■ to help restore and stabilize the intestinal flora

■ for fever blisters and canker sores of herpetic origin

LACTINEX contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

First introduced to help restore the flora of the intestinal tract in infants and adults,[1, 2, 3, 4] LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.[5, 6, 7, 8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

in alcoholism:

B and C vitamins aid therapy. Therapeutic amounts of B and C vitamins can be important in the management of the alcoholic patient. In alcoholism, as in many chronic illnesses, STRESSCAPS vitamins aid therapy.

Stresscaps®

Stress Formula Vitamins Lederle

FOR PROFESSIONAL RECOMMENDATION ONLY

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

DORSEY "FLU-GRAM"

DON'T BE LULLED BY RELATIVE LACK OF FLU LAST WINTER. THIS WINTER BE PREPARED: WHEN THE COMPLAINTS ARE COUGH AND CONGESTION, YOU CAN RELIEVE THESE SYMPTOMS WITH TUSSAGESIC TABLETS. ONE TIMED-RELEASE TABLET AT MORNING, MIDAFTERNOON AND BEDTIME BRINGS UP TO 24 HOURS' RELIEF FROM TROUBLESOME COUGH AND STUFFED AND RUNNY NOSE. TUSSAGESIC IS THE FAMOUS TRIAMINIC FORMULA, PLUS THREE OTHER PROVED CONSTITUENTS. MAKES PATIENTS MORE COMFORTABLE. FAST. ASK YOUR DORSEY REPRESENTATIVE FOR SUPPLY OF STARTER SAMPLES, OR IF FLU IS ALREADY EPIDEMIC, PHONE COLLECT. SEE BELOW.

each

Tussagesic®

timed-release tablet contains:

Triaminic® (phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	50 mg.
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. Side effects: Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. Precautions: The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

President's Letter

THE TIME has come again for a changing of the guard, though the mainstream of medicine goes on with little regard for these minor surface alterations. Nonetheless, we should commend Doctor Sheppard for his stewardship in the last year, with the full knowledge that his participation and contributions will continue. We should hail also the Council of the State Medical Association and its able chairman, Doctor Sather. These physicians have given generously of their time in shaping the destiny of our Association. Finally, let us salute Mr. Brunn and his staff, newly ensconced in shiny quarters, a fitting environment for these competent and dedicated assistants.

Medicine is never without its problems, and these are likely to be highlighted in an election year. Throughout the forthcoming months, it is hoped that we can explore these areas with the advice and assistance of the splinter societies which come under the state organization umbrella. In such event, this President's page will feature officers of these societies.

On behalf of the Minnesota State Medical Association, its Council and Officers, and the Executive Secretary and Staff, I offer greetings in this new year. May it be prosperous, healthy and interesting!

O. L. N. Nelson, M.D.
President
Minnesota State Medical Association

Food for Thought (radio commentary): A few make things happen; a slightly greater number watch things happen; the large majority is unaware that anything is happening. Does this apply to our medical community?

Little did we guess that what has been called "The Century of the Common Man" would witness as its outstanding feature more common men killing each other with greater facilities than any other five centuries put together in the history of the world.—Winston Churchill, 1949

Patriotism

He is most worthy of his country who loves it, and refuses to live on *it, but lives* for *it.—Sunshine Magazine*

EFFORTS AT DEVELOPING a suitable pump for use in constructing an artificial heart have led to the evolution of many novel devices. As yet no device has exhibited sufficient all around performance to permit it to serve as a satisfactory heart substitute. Failures can be attributed basically to two inherent problems common to all devices currently under study: the inefficiency of the units and destruction of blood elements. The former deficiency seems to have presented the more formidable obstacle.

Practically all efforts to date have centered on a study of pumps producing a pulsatile type of flow. Selection of such pumps seems to have been predicated on reasoning that it would be wise to duplicate the normal physiological state (pulsatile flow), and that such units seem to lend themselves to design features by which blood destruction can more readily be prevented.

Nonpulsatile pumps have been described as the ideal heart substitute from the engineering point of view because they possess hydrodynamic characteristics analogous to the mammalian heart.[5] Such pumps do not contain valves; the advantage related to this characteristic has been recognized.[1-4] In addition, they are the most efficient type pump known. Despite these advantages such pumps have been almost universally ignored and apparently no serious efforts have been made to utilize them as artificial heart pumps. This unpopularity has stemmed from the fact that such units have had the characteristic of producing high shear and turbulence and, when tested, have produced a "Waring Blender effect" with marked destruction of the formed elements of the blood.[5] It occurred to us that, since in all other respects such pumps were potentially ideal for use as artificial hearts, attention should be focused on overcoming this single drawback. We felt that with imag-

*Veterans Administration Hospital, Houston, Texas.
**Veterans Administration Hospital, Syracuse, New York.

inative design conception this problem could be surmounted.

With this view in mind we designed, constructed, and tested a nonpulsatile pump. Results of tests carried out on this prototype are described herein. The findings indicate that the objectives have been met in fashioning a pump which retains the desirable engineering features of a nonpulsatile pump while at the same time possessing the capability to circulate blood atraumatically.

Description

The nonpulsatile pump tested operates on the principle of force-vortex or rigid-body motion. For force-vortex motion the tangential velocity is $v_\theta = \omega r$ where ω is the angular velocity and r is equal to the radius. Substitution in the differential equation for pressure gives

$$dp = \rho\omega^2 r dr - \rho g dz$$

where p = pressure, ρ = density, g = gravitational acceleration, and z = elevation.

The pressure difference between any two points in the fluid is

$$p_2 - p_1 = \rho\omega^2 (r_2^2 - r_1^2)/2 - \rho g (z_2 - z_1)$$

where r_1 and r_2 = the radial distances from the center of rotation to points 1 and 2 respectively

p_1 and p_2 = the pressures at points 1 and 2 respectively

z_1 and z_2 = the elevations at points 1 and 2 respectively (3)

In the pump tested, the fluid was constrained from taking the shape of a paraboloid of revolution by the rigid rotator. Therefore, the pressure difference is

$$p_2 - p_1 = \rho\omega^2 (r_2^2 - r_1^2)/2$$

where p_2 = outlet pressure

p_1 = inlet pressure

r_2 = outer radius of rotator

r_1 = inlet radius

This principle of pumping was selected because it offered the least amount of impact on the blood to obtain the pressures and flow rates necessary. The pressures and flow rates were

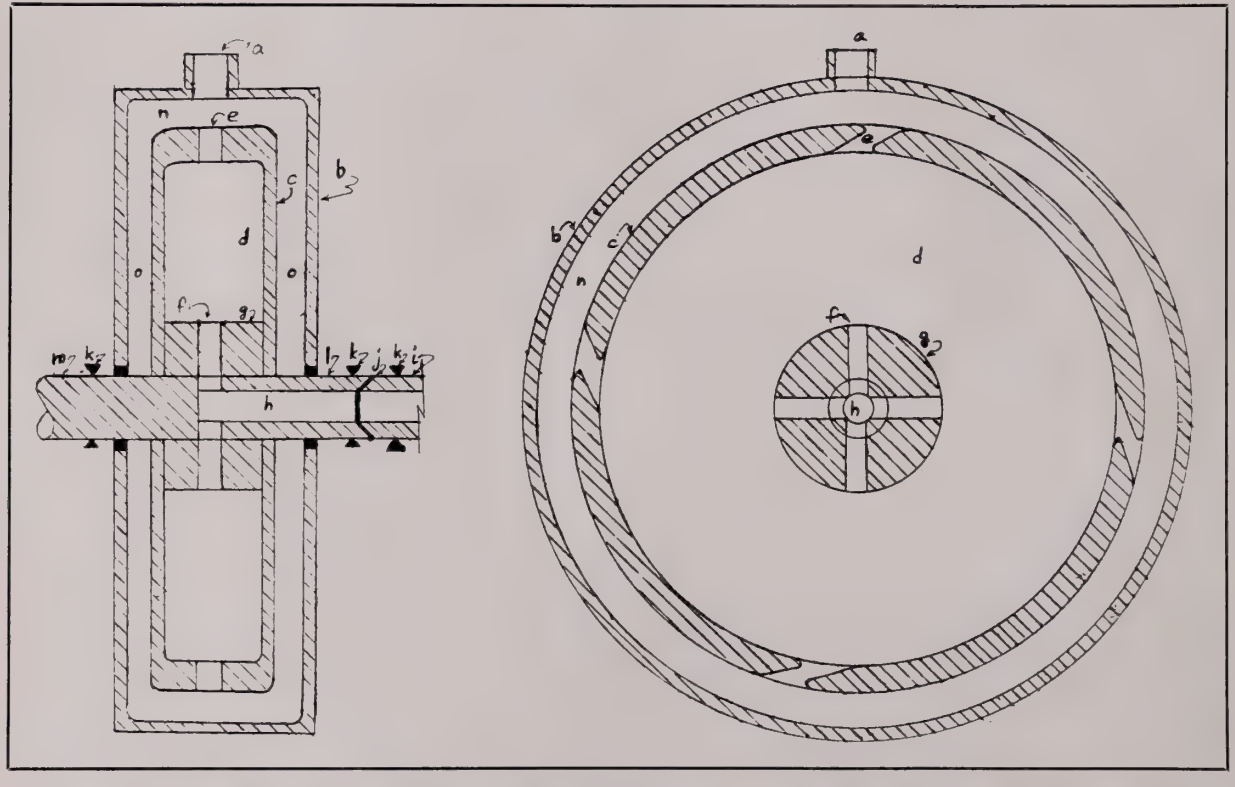

Fig. 1—Schematic cross-sections of artificial heart: (a)—pump outlet, (b)—pump housing, (c)—rotator, (d)—rotator chamber, (e)—rotator outlet, (f)—rotator inlet, (g)—shaft-to-rotator connector, (h)—pump inlet, (i)—stationary teflon inlet, (j)—teflon-to-teflon seal, (k)—bearings, (l)—rotating inlet shaft, (m)—stainless steel pump shaft, (n)—head space, (o)—side space. Plexiglass was used as the construction material for a, b, c, and g. Dimensions: External diameter, rotator, 8½″; External width, rotator, 1¾″; Internal diameter, pump housing, 11⅛″; Internal width, pump housing, 3¼″; Internal diameter, teflon inlet, ½″; Internal diameter, pump outlet, ½″; Outlet and inlet diameters, rotator, ⅜″.

obtained from this principle by imparting a revolutionary motion to the fluid through contact with the rotator walls. The particles of fluid in contact with the rotator walls have imparted on them, due to shear forces, an acceleration. Again, due to shear forces between fluid particles, these particles in turn exert a similar acceleration and force on their neighboring particles. Therefore, in essence, once the initial fluid particles have been accelerated, the rest of the fluid rotates through contact with other fluid particles. Hence, after this initial acceleration the fluid itself (rather than an impeller) becomes the prime mover. This action results in very gentle handling of the fluid.

Figure 1 schematically shows in cross sections the design features of the pump.

Methodology

The pump was subjected to *in-vitro* studies with water, saline, and blood each separately used as the circulating fluid. Performance was then measured by determining pressure head developed, volume output, and efficiency at r.p.m. between 425 and 820. Pooled citrated dogs' blood was used to prime the unit after the internal chambers of the pump were siliconized. The blood was then continuously circulated by the pump through a semi-closed system (Figure 2) for 3½ hours. Temperatures were kept normothermic by producing the proper friction on the bearing surrounding the input port. Serial hematocrit and plasma hemoglobin determinations were done at the beginning and hourly after institution of circulation. Red blood count, white blood count, and platelet determinations were done prior to commencement of and at the conclusion of the period of circulation. Blood samples were collected from the reservoir. Clotting time, clot retraction, and fibrin studies were performed at the conclusion of the experiments. R.p.m.s were measured by means of a stroboscope. In addition, stroboscopic analysis was utilized to study characteristics of fluid flow with water and saline.

Pump efficiency determinations were made by using a calibrated motor to determine input power to the pump at various r.p.m.s, and pressure and flow readings were taken to determine hydraulic power.

Results

Pump efficiencies in the order of 45% were attained.

Figure 3 depicts flow rates achieved against various heads of pressure with water as the circulating fluid with an input pressure of zero. Approximately doubling the r.p.m.s resulted in a 2-to-4 fold increase in flow rate depending on the given peripheral resistance. Essentially similar patterns were obtained when either saline or blood was used as the circulating fluid at a given r.p.m.

During the test periods there was no increase in plasma hemoglobin. No change was detected in the red blood count, white blood count, or hematocrit. Platelets were normal in appearance and numbers at the conclusion of the period of circulation. No defibrinization took place. Neutralization of the citrate effect on the blood with calcium chloride at the conclusion of the tests resulted in prompt clotting of the blood (2½ minutes). Clot retraction in quality and time was normal from blood samples collected at the end of the experiment.

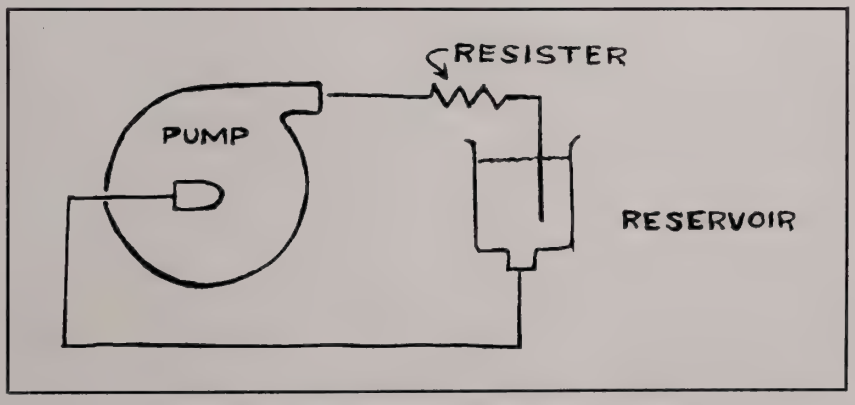

Fig. 2—Schematic diagram of semi-closed system.

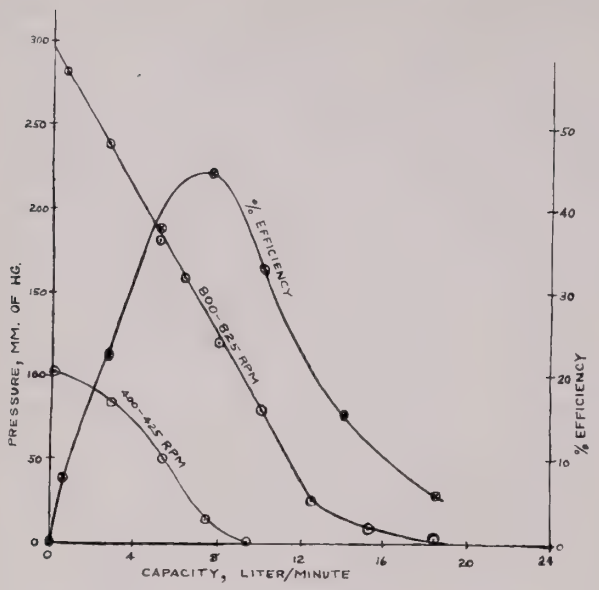

Fig. 3—Capacity vs. pressure and % efficiency.

Discussion

The nonpulsatile pump described exhibits high performance characteristics from the standpoint of efficiency (on the order of 45%) and ability to pump blood without detectable damage.

The prototype which was constructed for these experiments represented only a very crude device fashioned from available "odds and ends." It was fabricated with the sole purpose of establishing the validity of the pumping principle involved. Higher efficiencies should be attainable in more refined models. Streamlining the design, based on data gathered from prototype studies, and careful selection of compatible construction materials should extend the already very impressive blood tolerance characteristics of the pump.

Optimization will involve studies as to the most desirable rotator configuration. Figure 4 depicts three alternate rotator designs immediately under study as possible configurations to supplant disc-shaped rotators. Figure 5 schematically illustrates what we feel may ultimately constitute the optimum mechanical design of this pump. The most desirable number of rotators and their spacing in a given pump have yet to be determined. In the experimental model, for sake of convenience of construction, the inner walls of the housing were stationary; engineering principles suggest that if rotary motion were imparted in the same direction as the rotators to those portions of the pump, it would enhance efficiency and reduce turbulence and shear even further. An even more attractive approach currently under study by our group would be to eliminate the head and side space portion of the pump altogether. Because of the nature of this pump the head and side space can be eliminated in order to achieve

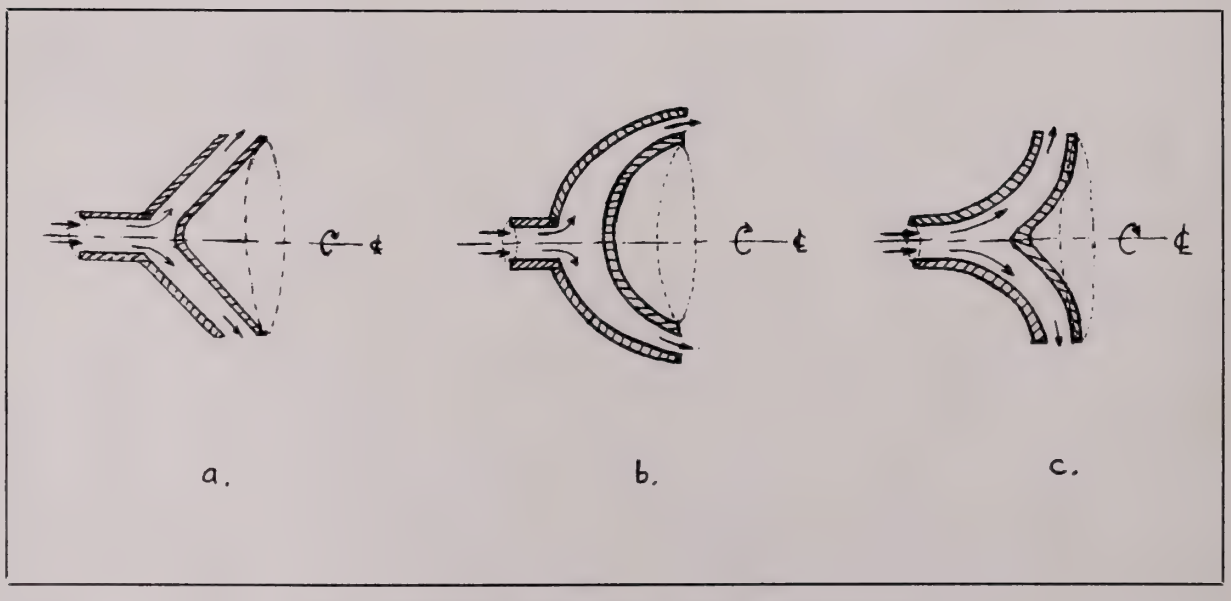

Fig. 4—Schematic Cross-Sections of Three Types of Rotators.

a more compact unit. Studies have been carried out in our laboratory in connection with the staging of such pumps. It has been found that it is possible in this fashion to trade off r.p.m.s for stages to reduce the former to the desired speed. The effect is to lengthen the device at the expense of width. Calculations indicate that a very compact unit can be constructed in this manner and yet obtain the pressure heads and flow rates desired.

The physiological necessity of pulsatile flow is still a moot question.[1,2] From studies we have done it appears possible to easily convert a nonpulsatile to a pulsatile type flow. Thus, should the latter type flow in the future be found to be physiologically necessary, the present type pumping unit is readily adaptable to such conversion. In the meantime, this pump provides an ideal model for use in the study of nonpulsatile flow in both *in-vitro* and *in-vivo* experiments. It should also find application as an atraumatic, efficient heart-lung machine pump.

It is worthy of mention that the only animals available at the time these experiments were carried out were unfasted sick dogs suffering from distemper and heart-worm infestations. Use of blood from these animals we feel resulted in a more critical test of the pump's ability to handle blood atraumatically.

Our observations are in accord with those of Saxton and Andrews,[5] namely, that such pumps as these are auto-regulatory according to physiological requirements, and with right and left heart units operating simultaneously would automatically maintain balanced flows between the two sides. In the nonpulsatile pump they tested (a centrifugal pump) they noted a marked decrease in output when blood was substituted for saline. We found in our pump that there was essentially no difference in flow rates or pressure heads developed, whether water, saline, or blood was used as the circulating fluid.

We agree with the contention of Saxton and Andrews that these type pumps embody qualities which make them potentially ideal artificial heart pumps.[5] However, they found the particular unit which they tested caused marked destruction of the formed elements of the blood. We feel they got the "Waring Blender effect" they noted because, in essence, they used a "Waring Blender." We postulate that the drop in efficiency and output they experienced on using blood was due to the "Waring-Blender effect" causing cavitation of this fluid because of the dissolved gases. The cavitation undoubtedly also contributed to the hemolysis.

Conclusions

A nonpulsatile pump is described embodying

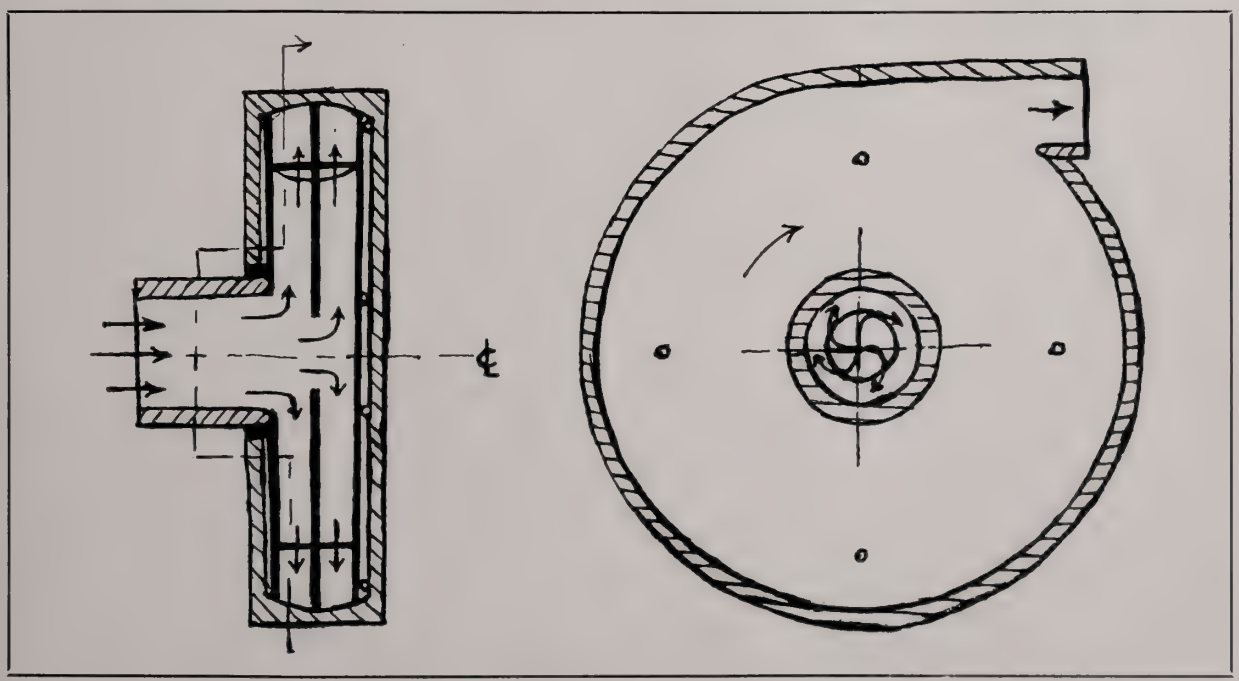

Fig. 5—Schematic cross-sections of optimized design.

a unique pumping principle. It has high efficiency and the ability to handle blood atraumatically. It is proposed that it will find application for both intracorporeal and extracorporeal uses, and for use in other situations when gentle handling of a fluid medium is desired. Based on our preliminary *in-vitro* findings it is our opinion that the perfection of this type of pump could represent a breakthrough in the search for a pump to ultimately serve as an artificial heart. Further studies are under way to optimize the unit.

Acknowledgments

We are deeply grateful to Dr. Fred B. Vogt, Chairman, Department of Biomedical Engineering, Graduate School of Biomedical Sciences at Houston, and Louis Meharg, Ph.D. (E.E.) of the Department of Biomedical Engineering, Graduate School of Biomedical Sciences at Houston for their review and analysis of our results and calculations.

Ortner's Syndrome

Laryngeal paralysis due to compression of the recurrent laryngeal nerve has been reported to occur in certain types of heart disease. Alexander first described these related conditions in 1904. The syndrome has been reported in one patient with mitral disease and in another patient who showed cardiosclerosis with hypertension and heart failure. When the laryngeal paralysis occurs on the left side, it is a result of recurrent nerve compression caused by dilatation of the left branch of the pulmonary artery just below the arch of the aorta.

What Is Wrong?

When you talk with the patient, you should listen first for what he wants to tell, secondly, for what he does not want to tell, thirdly, for what he cannot tell. He does not want to tell things the telling of which is shameful or painful. He cannot tell you his implicit assumptions that are unknown to him, such as the assumption that all action not perfectly good is bad, such as the assumption that everything that is not perfectly successful is failure, such as the assumption that everything that is not perfectly safe is dangerous.*

Cesarean Hysterectomy*

DONALD R. JANES, M.D.**
REGINALD A. SMITH, M.D.†
TIFFANY J. WILLIAMS, M.D.‡
Rochester, Minnesota

BECAUSE OF A recent trend in some centers toward performing hysterectomy after indicated cesarean section when future pregnancy was contraindicated, we reviewed the experience with cesarean hysterectomy at the Mayo Clinic in the past 15 years.

History of Cesarean Hysterectomy

Early in the 16th century the first cesarean section was performed. The operation at that time was used primarily to save the life of the infant. The mother often died of exsanguination or peritonitis, since the uterine wound was usually left open. The first cesarean hysterectomy, a subtotal procedure to control bleeding, was reported by Bixby[1] in 1869; unfortunately, the woman died 78 hours after the procedure. In 1874, Porro first showed experimentally in rabbits that the death rate was reduced after cesarean section by removal of the uterus. This principle was applied by Porro[2] in 1876, when he performed the first successful cesarean hysterectomy. Harris[3] reported that from 1876 to 1880 there were 50 cases of cesarean hysterectomy, with a maternal mortality rate of 58%. Opposition to the removal of the uterus was voiced in 1882 by Sänger,[4] who indicated that closure of the uterine wound with sutures eliminated the necessity for removal of the uterus. Early in the 20th century, intrapartum infection became the most important indication for cesarean hysterectomy. In 1952, however, Kobak and associates[5] reported that none of the 200 women severely infected after cesarean section who were treated with antibiotics died; thus, infection as an indication for cesarean hysterectomy was seemingly eliminated.

Prior to 1950, cesarean hysterectomy was usually carried out as emergency treatment for overwhelming infection or for control of hemorrhage. Of late, the operation has been done electively in some centers for a variety of indications, most commonly in women near the end of their reproductive period in whom the uterus no longer serves a useful function. Davis,[6] after a review in 1951 of 140 cases of total cesarean hysterectomy, and Montague,[7] after a study in 1959 of 75 such cases, stated that cesarean hysterectomy is the procedure of choice when both cesarean section and sterilization are required. Pletsch and Sandberg,[8] in 1963, also supported this thesis. They stated the belief that a relatively minor operation cannot be entirely justified if a more extensive procedure offers greater advantages to the patient without unduly increasing the risk. A rather different viewpoint was expressed by O'Leary and Steer[9] in 1964. They concluded that cesarean hysterectomy was associated with greater blood loss at surgery, an increased incidence of urinary tract injury, and a higher rate of morbidity. This statement was based on the review of 165 cases of cesarean hysterectomy. Two thirds of the patients required blood transfusions during or after the procedure. There were four bladder perforations and two vesicovaginal fistulas. The morbidity rate was approximately twice as great when compared to the morbidity rate associated with cesarean section followed by tubal ligation. They also noted that it was difficult to determine whether the cervix was totally removed at cesarean hysterectomy. This difficulty partially defeated the purpose of the procedure in prevention of future gynecologic disorders. In 1957 Dyer[10] reported cerebral thrombosis, peritonitis, and pulmonary embolus in his extensive series involving cesarean hysterectomy.

Present Study

The records of patients who had had cesarean section performed at the Mayo Clinic from January 1952 to September 1966 were reviewed. During this period there were 23,189 deliveries, of which 789 were by cesarean section. Tubal ligation was done at cesarean section on 64 occasions, and there were 25 cesarean hysterectomies.

*See Test Your Word Score Page 53.

The 25 cesarean hysterectomies may be subdivided into two major groups: emergency cesarean hysterectomy as a life-saving procedure to prevent exsanguination during cesarean section, and elective cesarean hysterectomy when the operator judged that the future health and well-being of the patient would be best served by removal of the uterus at cesarean section. Elective cesarean section was always performed for obstetric indication and hysterectomy for a separate indication. There were 23 total cesarean hysterectomies, and two subtotal procedures. One subtotal hysterectomy was performed because of hemorrhage and shock and the other because of sepsis. Emergency cesarean hysterectomy was carried out in seven instances: four for abruptio placenta, two for acute rupture of the uterus, and one for placenta percreta.*

Indications

Malignancy

Eighteen of the cesarean hysterectomies were classified as elective: five involved cancer and 13 involved benign conditions. In two cases the Wertheim-type hysterectomy was carried out at cesarean section for stage I carcinoma of the cervix. In two cases—one of carcinoma of the ovary associated with pregnancy and the other of carcinoma of the bowel associated with pregnancy—radical procedures were done. The fifth case was one of cancer of the breast, with metastatically involved axillary lymph nodes in which oophorectomy was indicated. The uterus was also removed at that time. In the 13 cases in which the uterus was removed because of various benign conditions, the most frequent indication was the presence of multiple uterine leiomyomata; these were noted in five cases. The next most frequent indication was that of a defective uterine scar, occurring in four instances. Two uteri were removed because of prolonged labor with incipient intra-uterine infection. Two others were removed because of extensive uterine damage not associated with hemorrhage. There was one case in which the mother had undergone multiple procedures for an imperforate anus; an anomalous uterus was removed at cesarean section. In no case was cesarean section carried out solely for the purpose of steri-

lization.

Morbidity and Complications

As might be expected in the group who underwent emergency cesarean hysterectomy, the incidences of blood loss and morbidity were high (morbidity being defined as a temperature of 100.4 F on any two postoperative days). In one patient with placenta percreta, 31 units of blood were infused. This patient had had a temperature of more than 100.4 F. on 11 postoperative days. Cardiac arrest occurred, requiring defibrillation, and a tracheotomy was necessary to relieve obstruction. The patient is alive and well. One woman with abruptio placenta required eight units of whole blood during removal of the uterus and had fever for three days. Another woman, with traumatic extension of the uterine incision, also required eight units of blood and had fever for four days.

The morbidity associated with elective cesarean hysterectomy for cancer was surprisingly low. One patient with stage I cancer of the cervix required two units of whole blood during surgery and had a temperature of more than 100.4 F. for three days. In the group undergoing elective surgery because of benign conditions, one patient required three units of whole blood during removal of the uterus for multiple uterine fibroids, and another required two units of whole blood during hysterectomy for prolonged labor and probable uterine infection. The first patient had a fever for two days, and the second for four days. In the group undergoing elective cesarean hysterectomy, there was one maternal death, a 42-year-old woman, gravida 1, who underwent cesarean section because of pelvic contraction and nulliparity. This patient had suffered for years from a congenital prolapse of the uterus in which the cervix and lower uterine segment protruded 4 cm. beyond the vulva. During the course of the hysterectomy the bladder was opened. Intravenous tetracycline was administered during the postoperative course. Azotemia and jaundice developed, and the patient died on the twelfth postoperative day. Autopsy revealed acute, yellow atrophy (fatty infiltration) of the liver, with bile necrosis.

Thus for both the emergency and the elective group, the rate of morbidity was 24%, and for the elective group alone it was 15.4%. All patients who had morbidity also had significant blood loss.

Fetal Outcome

In the group undergoing emergency cesarean section, there were five full-term infants, three of which were stillborn and two of which survived; there were two premature infants, both of them stillborn. In the five cases involving treatment of carcinoma, two infants weighing more than 2,500 cm. survived, and three infants weighing less than 2,500 cm. were stillborn. All infants in the 13 remaining cases of elective cesarean section survived.

Discussion

If the results of cesarean section followed by hysterectomy are to be compared with those of cesarean section followed by tubal ligation, only conditions that allow a choice of either procedure should be studied. Eliminated, therefore, from the comparison should be all cases of emergency cesarean hysterectomy carried out as a life-saving measure in which no choice but removal of the uterus was available. Also eliminated from comparison should be cases in which extensive surgical procedures for treatment of carcinoma are involved. We are left with a group of truly elective conditions, in which the surgeon is faced with a choice of removing the uterus or ligating the tubes. Specifically, in this series are the cases that involved uterine myomas, defective uterine scar, probable uterine infection, uterine prolapse, and multiple congenital anomalies.

In 1965, Jensen and Aaro[11] reviewed all cases involving cesarean sections at the Mayo Clinic during the previous 10 years and reported that there were 532 cesarean sections carried out—an incidence of 3.3% of all deliveries. Morbidity, as defined by the joint committee of maternal welfare, was noted in 10.3% of the cases. The most common causes were endometritis, urinary-tract infection, and pneumonitis. There were three cases of wound infection, one case of deep thrombophlebitis, and one of pelvic hematoma. The average number of febrile days in their series was 2.8.

Thirty-five patients in Jensen and Aaro's series had tubal ligation; none required blood transfusion and six experienced morbidity (17.1%). There were no complications or deaths in the group that underwent cesarean section and tubal ligation.

Also to be considered is the patient with uterine disease necessitating hysterectomy. Some authors have stated that cesarean hysterectomy is indicated in these cases. When defined in terms of temperature, morbidity in cesarean hysterectomy is comparable to that in hysterectomy alone. However, the serious complications of urinary-tract injury and excessive blood loss associated with cesarean hysterectomy eliminate this operation as an elective procedure.

Conclusion

Throughout the literature and in the present series, cesarean hysterectomy has been shown to be a life-saving measure in conditions causing acute blood loss during indicated cesarean section. But elective cesarean hysterectomy, both in this series and in others, is associated with an unacceptably high primary morbidity and complication rate. However, balanced against this increased morbidity and complication rate is the long-term consequence of leaving an abnormal uterus in situ. Large fibroids may degenerate, or they may be associated with subinvolution of the uterus and delayed hemorrhage. Low-grade endometritis, especially in an extensively damaged and repaired uterus, may become an overwhelming peritonitis. Ligated uterine tubes occasionally regain patency. The surgeon, then, must weigh the acceptable morbidity in cesarean hysterectomy against the seriousness of the disease present. When indicated cesarean section is associated with relatively minor uterine disease, the conservative course favors cesarean section and tubal ligation. Cesarean hysterectomy should never be carried out when sterilization is the only indication.

Zonotherapy

One Dr. Fitzgerald of Hartford, Connecticut, has divided the body into zones, lengthwise and crosswise, and heals disease in one zone by pressing on others. To keep the pressure going he developed little wire springs. For instance, a toothache on the right side may be "cured" by fastening a little spring around the second toe of the left foot. Naturally, Fitzgerald has never convinced anyone with ordinary reasoning powers that there is anything in his system—except what he gets out of it.*

Nafcillin for Prophylaxis in Oral Surgery

DANIEL E. WAITE, D.D.S.*
WILLIAM J. MARTIN, M.D.**
ALEXANDER SCHIRGER, M.D.**
Rochester, Minnesota

Members of our group have previously reported data on the use of phenoxymethyl penicillin, erythromycin, and cloxacillin for the prevention of postoperative bacterial invasion of blood after oral surgical procedures.[1-5] In continuing these studies, nafcillin (Unipen), a semisynthetic penicillin containing an ethoxynaphthyl side chain, was used. On oral administration, nafcillin produces serum levels that may be lower than those obtained with oxacillin, but nafcillin persists longer in the serum and may provide better tissue penetration.[6] The purpose of this study, as it has been with the others, was to test the effectiveness of the selected antibiotic agent under the conditions outlined.

Methods and Materials

The patients were selected for this study solely on the basis of their need of oral surgical procedures. The surgical problems consisted mostly of impacted third molars and full-mouth extractions because of periodontal disease or caries or both. Nafcillin† in capsule form was administered orally to 29 patients in four successive doses of 250 mg., beginning 18 hours prior to operation. An additional 25 patients received 500 mg. of nafcillin orally in four successive doses, also beginning 18 hours prior to operation. Blood for cultures was drawn immediately after the operative procedure, while the patient was still in the operating room, and again approximately 18 hours later. No patient was included who had either preexisting or known infection, valvular heart disease, or a combination of these problems. Of the initial group of 29 patients, 10 had positive cultures of the blood obtained immediately after the surgical procedure (Table). In all 10, cultures of the blood obtained 18 hours after operation were negative. Of the 25 patients to whom 500 mg. of nafcil-

*Mayo Clinic and Mayo Foundation: Section of Dentistry.
**Mayo Clinic and Mayo Foundation: Section of Medicine.
†Supplied as Unipen, courtesy of Wyeth Laboratories, Philadelphia.

lin had been administered, three had positive cultures of the blood obtained immediately after the surgical procedure. However, all three cultures obtained 18 hours after operation were negative.

Comment

It is noteworthy that blood cultures in eight of the 10 patients receiving the 250-mg. dosage of nafcillin yielded *Streptococcus mitis*. The remaining two cultures were positive for *Bacteroides* and an anaerobic streptococcus. Of the three patients having positive cultures after oral administration of the 500-mg. dosage of nafcillin, all cultures yielded *S. mitis*. Despite the improved results after the higher dose of nafcillin, they did not approximate those noted in our patients who received optimal amounts of phenoxymethyl penicillin[1-3] or erythromycin[5] before operation and in whom cultures for *S. mitis* were consistently negative. As was true in our study of cloxacillin, these findings were not anticipated prior to our investigation, since nafcillin is generally considered effective against *S. mitis*. We had concluded a priori that the effect of nafcillin would likely be similar to that of phenoxymethyl penicillin and erythromycin against most organisms inhabiting the oral cavity, and that its antistaphylococcal effect would be greater than that of phenoxymethyl penicillin. The latter effect appears to have been achieved, since blood cultures from patients in the present series failed to grow staphylococci, in contrast to that seen in six of 94 patients receiving phenoxymethyl penicillin.[1-3] Nafcillin's antistaphylococcal effect under the conditions outlined is similar to that of erythromycin[4] and exceeds that of cloxacillin.[5] No patient who received nafcillin in either dosage form had positive cultures of blood taken 18 hours after operation. This finding can be contrasted to that encountered in our study employing cloxacillin, wherein two of 52 patients had positive cultures 18 hours after surgery.[5]

Data from the present study indicate that patients undergoing dental surgery should receive individual doses of 500 mg. of nafcillin rather than 250 mg. In this regard, there is general agreement that serum levels of nafcillin are higher when the subject is fasting and has had repeated doses. If decreased intestinal absorption of nafcillin were due to food ingested in the 18 hours before surgery, perhaps the increased dosage would result in higher serum levels and a more desirable antibacterial effect. Perhaps a more desirable antistreptococcal effect would result from the administration of nafcillin at intervals of every four hours for 24 hours, or even 48 hours, preoperatively. In any event, we recommend nafcillin in the dosage of 500 mg. in attempts to prevent bacterial invasion of the blood after oral surgical procedures.

Summary

Twenty-nine patients received nafcillin in amounts of 250 mg. in four doses by the oral route beginning 18 hours before oral surgery. In 10 of the 29 patients, cultures of blood drawn immediately after the operation grew bacteria. Eight of the 10 positive cultures grew *S. mitis*, one culture grew *Bacteroides*, and another grew an anaerobic streptococcus. Cultures of blood drawn 18 hours after operation in all 29 patients failed to grow any bacteria.

Twenty-five patients received nafcillin in amounts of 500 mg. in four doses by the oral route beginning 18 hours before oral surgery. Three of these patients had positive cultures of blood drawn immediately after operation.

TABLE
Positive Blood Cultures After Oral Operations With Nafcillin Administered Preoperatively in 54 Patients

Group	Dose*	Microorganism	Time after operation	
			Immediately	18 hours
29 patients	250 mg.	*S. mitis*	8	0
		Bacteroides	1	0
		Anaerobic streptococcus	1	0
25 patients	500 mg.	*S. mitis*	3	0

*Every four hours for four doses beginning 18 hours before operation.

All three were positive for *S. mitis*. Cultures of blood drawn 18 hours after operation in these 25 patients failed to grow any bacteria.

These findings can be contrasted to our experiences with patients who have received optimal amounts of phenoxymethyl penicillin or erythromycin preoperatively and in whom cultures for *S. mitis* have been consistently negative. Under the conditions of our studies, nafcillin's antistaphylococcal effect was similar to that of erythromycin and exceeded that of cloxacillin. In this same regard, nafcillin was more effective than cloxacillin in assuring negativity of cultures of blood obtained 18 hours after operation.

Papyrus Ebers
For Pains in the Limbs

'For Pains in All the Limbs' the Scribe (of the Egyptian Papyrus) made a good start by instructing the Patient to mix up Castor Oil with Honey; but in the next few lines he spoilt everything by telling him to smear this all over the outside of his body instead of swallowing it and allowing it to do its work internally. Of course having got off the track at the start he found it impossible to right himself and accordingly went from bad to worse, his next effort being a poultice of Locusts which have been ground up in a mortar with Butter and Spices. For 'Pains in the Bones in Every Limb according to the Truth,' he recommended a poultice of Black Knife-stone with Fat, Honey, and Saltpetre as adjuvants. But according to the truth as we know it the use of Black Knife-stone, with or without Fat, Honey, and Saltpetre, in this connection is entirely fallacious, and not to be commended. The same can be said of the special poultice for the Thigh:

Bean-meal
Meal-of-the-pesen-bread
Sea-salt
Human Urine
Cook into one and apply as a Poultice.

And also for the Front-of-the-Shins, which was, however, let down more lightly:

The Inner-of-the-Shadfish; what is found in its Head.
Soak in Honey and apply as a Poultice.
It will heal the patient forthwith.*

The Clyster

The clyster or enema was practiced by the Egyptians in all its intimate refinements. They were reputed to have learnt it from the sacred ibis. When constipated this intelligent bird relieved itself with its curved beak aided by its very long neck. The Egyptians were quick to learn and imitated the ibis, using an instrument in the shape of the bird's beak. In the fifteenth century the clyster syringe was rediscovered by Professor Gatenaria of Pavia.

This syringe was hailed with undisguised joy, particularly in France. For three hundred years the enema was one of the favourite remedies in all cases of physical discomfort. During the first years of the reign of Louis XIV, it was the mode at the French court. Ladies and dandies alike had three to four enemas a day in order to acquire a fresh and healthy complexion and the rich bourgeoisie did not lag behind.

There was a great choice of cylster mixtures, including extracts of orange blossom, angelica, bergamot and roses. The ladies of the Faubourg St. Germain, that classical home of boudoir erotics, concocted their own clysters from secret recipes whose ingredients they would not betray even to their best friends.

In those gallant days of the Rococo Age, when the syringe stood at its peak of fame, artists vied with each other to combine esthetic shapes with elegance and convenience in handling. Instruments, real works of art in their way, were made from tortoiseshell or mother-of-pearl inlaid with silver gilt. The expensive decoration delighted the eye and made people forget the unappetising purpose of the instrument.

To administer an enema "professionally" was considered a high art. The operator must not take the place by storm but like a trained sharp-shooter prepare for action and fire as soon as he catches sight of the enemy. The operator must also behave with dexterity and consideration and refrain from any movement until he has the target in sight. Then he must kneel down with deference, bring up the instrument with the left hand without undue haste or eagerness, lower the pressure pump *amoroso,* and set it in motion *pianissimo,* with care and without jerking.

The clyster became the ally of blood-letting and purging—an unholy trinity which the doctors let loose on the human race. Persons of quality and crowned heads in particular who were in the hands of the leading physicians felt the healing lash of this three-thonged knout. Within six months Louis XIII of France was subjected to 47 bleedings, 215 purgings and 312 clysters —two every day except holidays. His son, Louis XIV, would presumably have suffered worse had he not rebelled against the prescriptions of his doctors. During his reign he got away with a mere 38 blood-lettings. Nor were enemas particularly to his taste, and the doctors only managed to force a few hundred on him. On the other hand, he endured several thousand purgings, which his gluttony necessitated, in order to unburden the royal bowels. The record of cathartic therapy was undoubtedly held by King Charles II of England, who had to endure untold agonies before he was allowed to die, presumably of a brain hemorrhage.*

Smears from the Cervix

Cancer Cell Detection

A. H. WELLS, M.D.*
D. W. KUNDEL, M.D.*
K. L. HELWIG, M.D.*
D. L. MICHAELIS, M.D.*
V. G. GOLDSCHMIDT, M.D.*
Duluth, Minnesota

THIS REPORT is limited to a study of the results of examinations of smears from the cervix uteri submitted to us for cancer cell detection over a ten-year period by 99 physicians in 28 regional cities. There were 62,185 patient examinations. An unknown number of these smears were repeat examinations on the same patients during this period. Our five pathologists found 1,042 of these examinations showed positive smears (Table 1). Among these cases there were 395 women with proven malignancies of the uterus. These patients were treated for their carcinomas of the uterus in many of the communities from which the smears were sent.

During the first year (1956) of this ten-year period there were 1,764 women whose smears were examined (Figure 1). In 1965 there were 11,377 patients' smears studied. Thus during the ten years there was an average increase of 1000 examinations a year for a total of 62,185. The percentage increase in number of examinations compared to the total tests performed per year gradually fell from 57% to 8%.

Diagnoses

Table 1 has the distribution of numbers of patients found to have positive smears in the Papanicolaou classes II to V using our modified definitions of the classes (Table 1). Since there were 395 women with malignancies, and only 26% or 105 of these malignancies were considered clearly cancer cells or class V, one must conclude that this probably reflects some uncertainty and lack of experience, especially in the early years of our study period.

Carcinoma in Situ

The informative Table 2 reveals that in those patients with *original* class II smears in which tissue diagnoses were made, there was a

*Pathology Service of St. Luke's Hospital, Duluth, Minnesota.

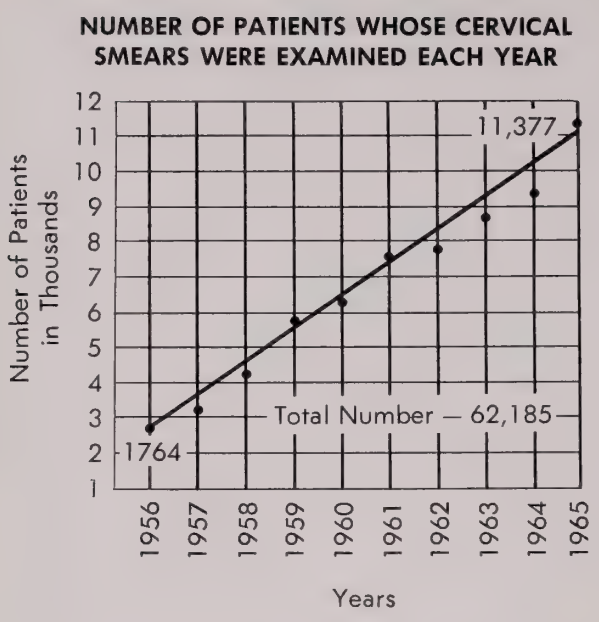

Figure 1

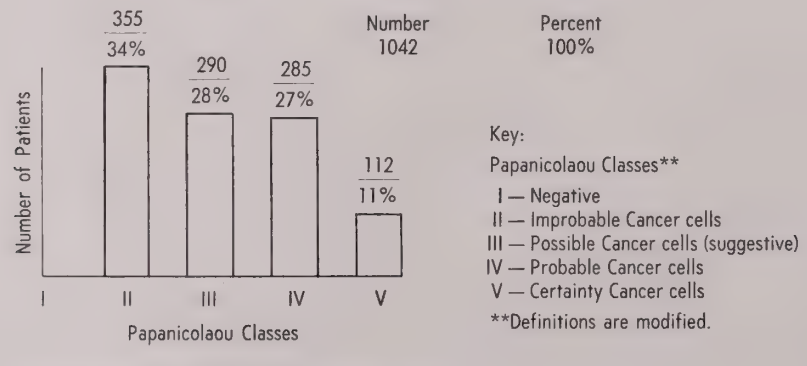
33% chance of the cervix having a carcinoma in situ. One should take into account that these patients had subsequent smears with higher class readings; otherwise a biopsy or more extensive surgical procedure probably would not have been done. As seen in Table 1, there were 355 class II readings, only 27 of which had tissue diagnoses. Ashe and Arey[1] found that 6.4% of their patients with cervical malignancies had class II readings on their original cervical smears.

Ninety-four per cent of the patients with carcinoma in situ of the cervix had original cervical smear readings in classes III, IV or V. With increasingly higher class readings the certainty of malignancy increased to class V where 91% of the patients had a uterine malignancy. During the ten-year period it was brought to our attention that we had made false-negative smear readings on two patients. These patients with carcinoma in situ of the cervix were found to have positive smears in the previous two weeks. The second cervical smear might very well be negative when a small area of malignancy has been rubbed off the cervix by the first examination. Time should be permitted for the cervix to recover from the trauma of the smear test before another smear or tissue diagnostic procedure is performed. The malignant lesion is sometimes lost as a result of surgical procedures. Thus a benign reading of tissue following conization may be a false-negative diagnosis and should have follow-up smears.

There were 334 patients with proven squamous cell carcinoma in situ of the cervix: 0.53% of the 62,185 examinations. This compares with 0.36% of 108,000 women found to have the same malignancy in a "Population Screening" project[2] in Memphis.



Invasive Carcinoma

It is apparent from Table 3 that conization of the cervix is valuable but not infallible in the diagnosis of carcinoma in situ. Eight or three per cent of the patients whose cone revealed an in-situ malignancy later were found to have an invasive squamous cell carcinoma in the hysterectomy specimen.

Ages of Patients

In Table 4 one finds the age groupings of

TABLE I
FREQUENCY OF POSITIVE DIAGNOSES IN FOUR CLASSES*

328 patients with carcinoma in situ of the cervix. The average age is 45.8 years—considerably younger than the average of 53 years in 51 women with invasive squamous cell carcinoma of the cervix (Table 5). Many authors[3,4,5] agree that one might expect to find either malignancy at almost any age. There is a ten-year variation in the average ages of women with either of these malignancies. Our averages are the highest found. In each group study, the eight to ten-year difference between the average of women with in-situ and invasive malignancies is constant and probably an indication of the time required for the in-situ carcinoma to become invasive.

Signs and Symptoms

carcinoma in situ was not possible with our sources of information. The frequency of symptoms and signs of cervices with this malignancy varies considerably in different groups reported.[3,4,5,8,9] Among others, Guseberg and Marshal[9] conclude that there are no characteristic signs or symptoms. Our physicians apparently did their surgical diagnostic procedures on the basis of the positive cervical smears and generally made little mention of the appearance of the cervix. Discussions with many of the physicians plus the great dominance of normal cervices when they were described in the charts lead to the speculation that in the majority of patients the cervices were entirely normal and the remainder probably had no more changes than might be expected in the average run of women.

It became apparent in this study that smears were frequently not taken from cervices with obvious carcinomas of the cervix. The great majority of these patients were diagnosed by small biopsies and immediately treated by radiation therapy. This accounts for the relatively few patients (51) with invasive carcinomas of the cervix in this study.

Treatment

Of the 226 attempts at cure of squamous cell carcinoma in situ of the cervix by hysterectomy there were five superficial recurrences on the adjacent vaginal surface (Table 6). These were discovered by follow-up smears and apparently cured by radiation therapy. There was a remarkable success of treatment of the 62 patients with in-situ carcinoma by conization and follow-up smear technique. Only 5% of this group had recurrence and were apparently cured by later hysterectomy. It will be noted in Table 3 that only 103 or 40% of the patients were apparently cured by the conization prior to hysterectomy. Our only explanation for this paradox is that some surgeons do a more extensive conization than others. This may be especially true if they wish to attempt a cure and not simply obtain tissue for a diagnosis. Giglio, Dowling and Jones[10] have concluded that conization alone is inadequate treatment, since in their experience 19% of the uteri had residual carcinoma after the conization.

A relatively high cure rate occurred in the invasive squamous cell carcinoma of the cervix group, where 30 of 36 patients were apparently cured by radiation therapy (Table 7). Hysterectomy alone in eleven women with superficial invasion (Stage 1) was followed by 10 apparent cures.

Non-Neoplastic Diagnoses

Trichomonas vaginalis* and Monilia require special attention and training to find them in cervical smears. Our early results had a much lower yield of positive organisms than later experience. Even today rushed examinations miss the diagnosis. Recently we have found 6 per cent of the patients to have trichomoniasis and 2 per cent moniliasis (Table 8).

A brief scan of a smear from the cervix in trained hands can permit an estimation of the maturation index of acceptable accuracy. It is generally agreed that a smear prepared from the surface cells of the vaginal wall in the

cul-de-sac area is more suited for cytohormone analysis. In spite of alterations by infections of the cervix and by scraping techniques of the cervical smear taken for cancer cell detection the rapid estimation of percentages of superficial cells, intermediate cells and parabasal cells yields sufficient information concerning the hormone status of most patients to warrant their usage routinely with cancer cell detection methods.

Costs

Handy and Wieben[11] report that their routine cervical smear examination of all hospital admissions in 25 participating hospitals during 1963 cost the New York State Health Department $718 (seven hundred and eighteen dollars) per confirmed case of malignancy found. Our ten-year experience with 62,185 women cost the patients examined $787 (seven hundred and eighty-seven dollars) per malignancy found. As indicated above, the great majority of our group of women with an obvious lesion of invasive carcinoma of the cervix did not receive a smear examination but did have the more efficient and direct biopsy. Thus the cost per case of malignancy found was increased in the remaining women examined. Considering the added sophisticated information on cytohormone analysis and trichomonas infestation given by our private enterprise, the added expense, if any, does appear to compare favorably with a large scale public health program.

Conclusions

1. A ten-year total of 62,185 patients had cervical smear examinations leading to the final diagnosis of uterine malignancies in 395 patients, an incidence of 0.63% in the examinations which included numerous repeat smears on the same patients.
2. Of the 62,185 examinations 1042 or 1.6% showed positive smear readings, 38% of these uterine malignancies.
3. Cervical smear examinations have increased by 1000 patients per year for the last ten years.
4. Although the average age of 328 women with squamous cell carcinoma in situ of the cervix was 45.8 years and that of the 51 women with the invasive variety was 53 years, both types of lesions occur at practically all ages.
5. Original class II readings on cervical smears should be followed by negative readings before being dismissed as unimportant.
6. With increasingly higher class readings on cervical smears the certainty of malignancy increased to class V where 91% of the patients had a malignancy.
7. The typical cervix with carcinoma in situ is a normal-appearing cervix.
8. All 226 patients treated by hysterectomy for carcinoma in situ of the cervix were apparently cured after five vaginal surface recurrences were detected by follow-up smears and treated.
9. There is a local trend to treat carcinoma in situ of selected patients by cervical conization and follow-up smears. Thus in 62 patients there were five recurrences which were then apparently cured by hysterectomy.
10. The question is raised whether bilateral oophorectomy at the time of hysterectomy for carcinoma in situ of the cervix does more harm than good?
11. Trichomonas vaginalis occurs in approximately 6% and moniliasis in 2% of the patients examined.
12. Routine maturation index estimations on cervical smears are frequently useful for selected patients.

A lady is a woman who makes a man behave like a gentleman.—Russell Lynes

Medicine and Religion

I have been to dinner with a group of doctors—they were talking freely among themselves, and they were sufficiently self-confident not to be afraid of saying unconventional things—when they began to discuss the possibility of a radical attack upon the degenerative disease known as old age. They did not consider it beyond all possibility of medical attack, but rather looked forward to the day—perhaps not too far in the future—when the time of inevitable death should be rolled back, perhaps into the indefinite future, and death would be accidental, as it seems to be with giant sequoias and perhaps some fish.

I am not saying that they were right in this conjecture (and I am quite sure that they would not claim it to be more than a conjecture), but the weight of the names supporting it was too great to allow me to reject the suggestion out of hand. Consoling as the suggestion may seem at first sight, it is in reality very terrifying, and above all for the doctors. For if one thing is clear, it is that humanity as such could not long survive the indefinite prolongation of all lives which come into being. Not only would the nonself-supporting part of humanity come to outweigh the part on which its continued existence depends, but we should be under such a perpetual debt to the men of the past that we should be totally unprepared to face the new problems of the future.

It is unthinkable that all lives should be prolonged in an indiscriminate way. If, however, there exists the possibility of indefinite prolongation, the termination of a life or even the refusal or neglect to prolong it involves a moral decision of the doctors. What will become of the traditional prestige of the medical profession as priests of the battle against death and as ministers of mercy? I will grant that there are cases even at present when doctors qualify this mission of theirs and decide not to prolong a useless and miserable life.

But what if such decisions, instead of being rare and unmentioned, will have to be made, not in a few special cases, but in the case of almost every death? What if every patient comes to regard every doctor, not only as his savior but his ultimate executioner? Can the doctor survive this power of good and evil that will be thrust upon him? Can mankind itself survive this new order of things?*

*Norbert Wiener: God and Golem, Inc., M.I.T. Press, 1964.

DERIVATIVELY SPEAKING

Scrofula—from Latin *scrofa* (brood sow), perhaps from a fanciful resemblance of the glandular swellings to little pigs.

The Journal of the American Medical Association reports this incident at the Mayo Clinic: A lady psychiatrist was questioning a patient and asked: "What would you say would be the difference between a little boy and a dwarf?" . . . The patient thought a while and said: "Well, there might be a lot of difference."

"What for instance?" asked the psychiatrist encouragingly.

"Well", replied the patient, "the dwarf might be a girl."

The Difference

"Hurrah!" cried the optimist, "I am finally at the end of my difficulties!" "Yes," murmured the pessimist, "but at which end?"

Dermoid Cyst Coincident with Stein-Leventhal Syndrome

Report of Case

IMMANUEL BENJAMIN, M.D.*
JOSEPH H. PRATT, M.D.**
Rochester, Minnesota

CONCOMITANT OVARIAN neoplasms in Stein-Leventhal syndrome are rare. Only isolated cases have been reported. Papillary cystadenoma,[1] thecoma,[2] arrhenoblastoma,[3,4] Leydig cell tumor,[5] adenofibroma,[6] and papilloma[6] have been present in ovaries affected by Stein-Leventhal syndrome.

In an analysis of 241 cases of Stein-Leventhal syndrome, Hutchison and associates[6] recently reported 11 cases in which various neoplasms of the ovaries were found. It is of interest that in five of the 11 cases the neoplasms were benign cystic teratomas. Recently, while doing a wedge resection we encountered a dermoid cyst in a polycystic ovary and, because of the rarity of this pathologic finding, we consider the case worth reporting.

Report of Case

A 21-year-old nulligravida Caucasoid woman came to the Mayo Clinic with the presenting complaints of primary sterility and oligomenorrhea. She had been married for 2½ years. Her menarche started when she was eight years old, and the next menstrual period came one year later. Menstruation had always occurred irregularly at intervals of two to 13 months. She had been taking Ortho-novum for about three months. During the course of medication her menstrual periods became regular, but after she discontinued taking this drug, her menses were again irregular.

The patient was five feet, five inches tall and weighed 166½ pounds. The pulse was 100 beats per minute and the blood pressure, 114 mm. Hg. systolic and 78 diastolic. She had moderate acne and the distribution of hair was normal. Her breasts were pendulous and her uterus was small. Results of laboratory tests were as follows: hemoglobin 14.3 Gm.; leukocytes 6,700; sedimentation rate 12 mm. in 1 hour; blood sugar 81 mg/100 ml.; VDRL negative. Urinalysis showed a specific gravity of 1.012, pH acid, sugar negative, and protein grade 1. Seventeen-Ketosteroids measured 10.8 mg. and ketogenic steroids 15.5 mg. The cervical pap smear was negative. Roentgenograms of the chest and skull showed no abnormality. On culdoscopic examination both ovaries were found to be twice the normal size. The capsule of each ovary was grayish white, smooth, and glistening. No evidence of ovulation was noted. Both tubes were visualized and appeared normal.

* Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Surgery.
** Mayo Clinic and Mayo Foundation: Section of Gynecologic Surgery.

A clinical impression of Stein-Leventhal syndrome was made and bilateral wedge resection was advised.

At laparotomy, preliminary dilatation and curettage showed proliferative endometrium. The abdomen was opened through a lower midline incision. There was no endometriosis. A 2-cm. fimbrial cyst was removed from the left tube. The ovaries measured 6 by 4 by 2 cm. with smooth capsules and no evidence of formation of corpus luteum; they were wedged longitudinally and enlarged with considerable cortical fibrous thickening, multiple follicular cysts 0.5 cm. in diameter to microscopic size, numerous developing primordial follicles with corpora atretica, and no corpora lutea. A 2-cm. dermoid cyst of the left ovary was found and removed (Figure). The patient's postoperative course was uneventful and she was dismissed after 11 days.

Figure. Longitudinal wedges from both ovaries with deep-seated dermoid in left ovary.

Comment and Summary

In Stein-Leventhal syndrome, ovarian neoplasia may be benign as well as malignant; thus any ovarian enlargement should be explored. Hormonal therapy is being utilized more commonly to treat these patients,[7-9] and unless one is aware of such coincident pathologic findings, moderate ovarian enlargement may be ignored. A culdoscopic examination should be performed, although in the patient whose case is reported this examination did not reveal the dermoid cyst, and even on exploration it was not obvious.

Appendicitis on the Frontier

Appendicitis was rare enough to disconcert a cowboy doctor suddenly confronted with it. In eastern Oregon, Dr. J. H. Fell and Dr. James Ashfor diagnosed a cattleman's severe abdominal pain as appendicitis, but neither doctor had ever seen an appendectomy. They anxiously questioned one another as to how the operation should be done. U. G. Cozad, bailiff of the court, overheard the doctors. He told them that a prisoner had committed suicide in the jail the night before.

"Maybe he had inflammation of the bowels," he said pointedly, and suggested a post mortem.

The two surgeons carried out the "post mortem," opened the dead man's abdomen, carefully reviewed their surgical technique, and planned their entry into their living patient. Satisfied with their dress rehearsal, they placed the appendicitis victim on a door stretched between two saw horses in a kitchen and successfully removed his appendix.*

Chronic Obstructive Airway Disease

Comparison of Match Test and Vitalor with Standard Pulmonary Function Tests

DAVID E. DINES, M.D.*
WARD S. FOWLER, M.D.**
Rochester, Minnesota

RECOGNITION OF breathlessness is not difficult, but describing the resultant impairment requires readily available and accurate estimates of pulmonary function. Such estimates may be obtained by using certain tests of pulmonary function. Although the tests are adjunctive to an adequate history and physical examination, an accurate diagnosis of the condition as well as management and treatment of the patient with pulmonary disease may depend on them. Roentgenograms of the chest, electrocardiograms and, in selected cases, blood gas determinations, pulmonary scanning, and angiograms may also be necessary in the appraisal of a pulmonary problem. Estimation of adequacy of pulmonary function is essential in the assessment of operative risk. Significant chronic obstructive emphysema was frequently associated with fatal postoperative complications in a series of 199 surgical procedures.[1]

A type of pulmonary-function testing equipment should be familiar to each of us as clinicians—to enable us to recognize the early reversible cases of chronic pulmonary disease and to follow the course of patients under treatment. More widespread use of tests providing accurate measurements will lead to more effective care of patients. Testing of pulmonary function need not require elaborate equipment.[2] Two relatively simple procedures will be described.

Testing Procedures

Match Test

The patient's attempts, by rapid exhalation through the open mouth, to extinguish a paper match at a distance of six inches (Figure 1) provide an estimate of the severity of pulmonary insufficiency. The test does not differentiate between an obstructive ventilatory impairment and a severe restrictive defect. A positive result to the match test implies a diminution of the 1-second vital capacity to

*Mayo Clinic and Mayo Foundation: Section of Medicine.
**Mayo Clinic and Mayo Foundation: Section of Physiology.

less than about 1,500 ml[3] and of the maximal breathing capacity (MBC) to less than 40 liters/min. or 50% of the predicted MBC.[4] Olsen[5] suggested that the match test may identify not only patients who have maximal breathing capacities of 40 liters/min. or less but also those who have maximal midexpiratory flow rates of 0.6 liter/sec. or less.

Vitalor

A bellows apparatus, such as the McKesson Vitalor (Figure 2), can be employed in the office or on the hospital ward to obtain the total vital capacity (VC), timed vital capacity or forced expiratory volume (FEV), and maximal expiratory flow rate (MEFR).[6,7] A nose clamp may be used to prevent escape of air. The patient inhales as deeply as possible. When the maximal inspiration is attained, an electric switch button on the instrument is closed to activate the recorder, and the patient is asked to exhale completely through the disposable mouthpiece into the bellows. This measures the total VC, provided it does not exceed the bellows' capacity of 4.8 liters. The timed VC is performed similarly with the patient making a forced, maximally rapid expiration after a maximal inspiration. The record showing several measurements is illustrated in Figure 3. The total volume expired represents the vital capacity, which may be compared with predicted normal values. Also shown is the volume expired in the first second, which normally represents about 80 to 85% of the forced VC.[8] The MEFR is calculated from that portion of the expiration curve beginning at 200 ml. and ending at 1,200 ml. The time required for the subject to exhale this liter of air is recorded. The average slope of this curve, properly located on the chart, indicates the MEFR, which normally exceeds 300 liters/min.[9,10] The record is also suitable for another measurement which determines the average flow rate of the middle 50% of the VC; this is designated as maximal midexpiratory flow rate and is expressed in liters per second.[11]

Impairment of ventilation is classified into three types: restrictive, obstructive, and combined. Restrictive ventilatory insufficiency (e.g., pulmonary fibrosis, pleural effusion, and resection of lung tissue) is indicated by reduction of the total VC but without slowing of expiratory air flow. Obstructive ventilatory insufficiency (emphysema, etc.) is indicated by time-volume relationships. The volume that is expired by maximal effort in the first second may be expressed in liters or as a percentage of the vital capacity performed. This is a valuable test in patients who have obstructive pulmonary disease and can readily be determined by the Vitalor. Figure 4 shows the expiratory pattern in chronic obstructive pulmonary disease. With advanced impairment, the total VC is reduced, but not as greatly as the expiratory flow rate. This is shown by the reduction in the volume expired in the first second (FEV_1) and its relation to the total VC, as well as in the midexpiratory flow rate.

Relation of Tests to Results

This report presents the relation of these simpler ventilatory tests to results obtained with more extensive established pulmonary function tests usually done on the same day.

Fig. 1—Position for match test. Match is held 6 inches from wide open mouth, and patient forcefully exhales after deep inspiration.

Fig. 2—Use of bellows apparatus (Vitalor). Results are recorded on graph at top of instrument.

The tests were conducted on 50 patients who had clinical evidence of pulmonary disease, usually of the chronic obstructive type, of varying degrees of severity. The group included 41 men and nine women, whose ages varied from 28 to 74 years (mean, 55 years).

Table 1 summarizes the results of the match test and spirometric tests measured with the Vitalor. No patient with FEV of less than 1.5 liters passed the match test. However, seven patients with FEV of greater than 1.5 liters failed. No patient with MEFR of less than 100 liters/min. passed, but seven with MEFR of 100 liters/min. or more failed. No patient with MMF of 0.6 liter/sec. or less passed, but four with values of 1.3 liters/sec. or more failed. It is possible that the patients with relatively good ventilatory tests who failed the match test might have passed with further testing efforts.

Table 2 presents results of other pulmonary function tests. Only one of 26 patients with maximal breathing capacity values of less than 60 liters/min. passed, but four with values of 90 liters/min. or more failed. The ratio of residual volume to total lung capacity (RV/TC), long used in evaluating severity of obstructive pulmonary disease, is associated with a progressive incidence of failure as RV/TC increases. Only one of 25 patients with RV/TC of 50% or greater passed, but three with RV/TC of 39% or less failed. All patients with obstructive disease who passed the match test maintained a normal level of arterial oxygen saturation during moderate exercise. The one patient who passed the match test, but in whom arterial desaturation developed, had diffuse pulmonary fibrosis without impaired expiratory flow.

These results agree with reports of Snider and associates[3] who found that passing the

match test implies that the FEV_1 is likely to exceed about 1.5 liters. Barry [12] similarly reported that passing indicates the $FEV_{0.75}$ to exceed 1.0 liter. We observed three patients who failed the match test despite values exceeding 2.0 liters. Also, passing the match test indicates MEFR to exceed 100 liters/min. and MMF to exceed 0.6 liter/sec. Olsen[5] related MMF to the match test using a shorter mouth-to-match distance (three inches); practically all failures were associated with MMF values of 0.6 liter/sec. or less; but at this distance many patients passed. Our results with MBC are similar to those of Snider and associates and indicate that passing the match test implies MBC values of 60 liters/min. or more; however, failures occurred above this level.

To assess the utility of the tests obtained with the Vitalor (VC, FEV, MMF, MEFR) relative to more complete tests, including the MBC and RV/TC ratio, the severity of obstructive impairment was graded separately for each group of measurements on a scale of 0 to 4, with 0 representing the least and 4 the greatest degree of impairment. The mean score (2.9) was the same for the two methods. In 60% of the patients the scores were the same by the two methods; differences of 1 scale unit occurred in the other 40%, with greater severity being indicated by Vitalor in 20% and by the extended tests in 20% (Table 3).

Summary

Fifty adult patients having chronic pulmonary disease, mainly of the obstructive type, were studied by the match test, with the Vitalor apparatus, and with more complete tests of pulmonary function. Ability to pass the match test was associated with values of FEV_1 greater than 1.5 liters, MEFR greater than 100 liters/min., MMF greater than 0.6 liter/sec., and MBC greater than 60 liters/min. Some failures were observed above all the levels listed. Arterial oxygen unsaturation during exercise by patients with obstructive disease was observed only in some of the patients who failed the match test. Similar gradation of severity of impairment was indicated by both Vitalor and more extensive tests.

In the physician's office, early detection of obstructive pulmonary disease, periodic evaluations, and assessment of operative risk are facilitated by relatively simple pulmonary function tests, particularly if the forced or timed vital capacity is recorded. These are useful adjuncts to the history, physical examination, and roentgenogram of the chest.

Case Report

A nine-year-old white female was admitted to the University of Minnesota Hospitals for the twelfth time on January 9, 1966. She was hospitalized for repair of an esophageal stricture present since March 1965. Starting at age 30 months this Caucasian child was repeatedly hospitalized because of recurrent staphylococcal infections, manifested primarily by furunculosis and pneumonia. Chronic pulmonary disease and bronchiectasis had developed by four years of age. At five years hypergammaglobulinemia with a normal distribution of immunoglobulins was found and there was a normal antibody response to immunization with typhoid and polio antigens. Serum antibodies to staphylococcal alpha hemolysin were present in low titer, with no detectable antibody to staphylokinase. The phagocytic and bactericidal capacity of polymorphonuclear leukocytes were found to be comparable to normal controls.[1]

In February 1965 there developed diffuse vasculitis with necrosis and eventual auto-amputation of three digits on each hand. Progressive stricture of the esophagus developed during this episode of vasculitis. No bacteria were recovered from blood, urine or exudate fluid.

Treatment for extended periods with either oxacillin or methacillin had been initiated in 1961 and the patient had received oxacillin daily for approximately 10 months before her final hospital admission. Oxacillin (150 mg/kg/day orally) was continued in the hospital. She was afebrile until eight days after admission when fever of 104° suddenly developed. Pneumococci were cultured from the blood. A sputum culture revealed *P. aeruginosa.* Penicillin (12,000,000 units/day I.V.) was given, and 18 hours after start of this therapy the patient was afebrile. A cervical esophagostomy was performed four weeks after admission; however, pneumonia, atelectasis and cardiac failure developed postoperatively and she expired seven days after surgery. Post-mortem blood cultures were sterile.

The pneumococcus isolated from the blood was type 9. Repeated tube dilution sensitivities with inoculum of approximately 1 x 10^6 bacteria per ml. showed resistance of the organisms to oxacillin at concentrations ranging from 3.1 μg/ml.-5 μg/ml. This degree of resistance was demonstrable after at least five subcultures of the organism on nutrient agar plates. Additional sensitivity

From the Department of Pediatrics, University of Minnesota College of Medical Sciences.

**Associate Professor of Pediatrics, University of Minnesota College of Medical Sciences.

studies (courtesy J. H. Lennon, Bristol Laboratories, Syracuse, New York) showed that in addition to increased resistance to oxacillin there was resistance to cloxacillin at 6.25 μg/ml. but sensitivity to penicillin G at 0.39 μg/ml.

Discussion

In 1963 reports appeared describing tetracycline-resistant pneumococcal strains.[2,3,4] Presently 18 isolates with resistance to this antibiotic have been recorded.[5,6] All but one of these strains were of pulmonary origin in patients with chronic bronchitis and many appeared in patients who had been treated with tetracycline for more than 12 days.[3,4] In addition to tetracycline resistance *D. pneumoniae* strains resistant to erythromycin and lincomycin have recently been reported.[7]

The sensitivity of clinical isolates *D. pneumoniae* to oxacillin has been reported to range from 0.04 to 0.8 μg/ml. Methicillin sensitivity ranged from 0.1 to 1.6 μg/ml. and sensitivity to penicillin G was 0.1 μg/ml.[8] It has been suggested that, since the minimal inhibitory concentrations of oxacillin, cloxacillin and nafcillin against non-penicillinase-producing gram-positive organisms are so relatively close to those of penicillin G, one of these agents could be used as initial therapy in all severe gram-positive coccal infections.[9] The recovery of a strain of *D. pneumoniae* with increased resistance to oxacillin and cloxacillin from a patient on oxacillin therapy indicates the need for determination of antibiotic sensitivity of pneumococci isolated from patients receiving antibiotics.

Recourse to History

Hippocrates made his mental cases drink human blood. He maintained that the blood of sound persons had a sound soul.

Some 400 years ago a theory was circulated that a man would become brave and generous if he takes blood from one who possesses either of these qualities.

Marie de' Medici, who lived in the early 17th century and was known for her cruelty, dreaded the prospect of old age and its attendant ailments. One of her court physicians suggested that she drink human blood.

At the close of the 15th century Pope Innocent VIII was treated with a potion also prepared from human blood.

Naturally, all these instances cost the lives of those whose blood was taken for the various potions. But they show that the idea of utilizing the healing powers of blood has occupied men's minds through the centuries.

The first blood transfusion from man to man was made early in the 19th century. It was made to a patient suffering from stomach cancer—a patient who in that day was doomed to die. . . . Andre Blondel, the physician who treated him, decided to try a blood transfusion. He had read about its prospects in medical journals, and had even tried it himself on animals. Though the journals condemned the idea as contrary to age-old medical precepts, the physician reasoned that his patient had nothing to lose.

The dying man was transferred to a hospital. One of the attendants agreed to give some of his blood. The transfusion was successful. A day passed, a second, a third, and there were no ill effects. The patient lived longer.

That was the first blood transfusion in history. It dates back to 1818.*

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

HALT DIARRHEA!
SHERIFF

LOMOTIL®

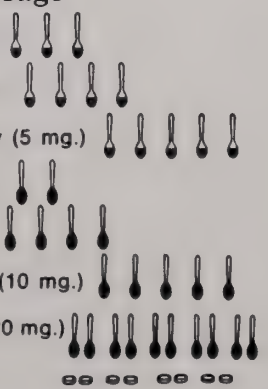
TABLETS / LIQUID

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride . . . . . 2.5 mg.
(Warning: may be habit forming)
atropine sulfate . . . . . 0.025 mg.

Halts Diarrhea Promptly

in children with . . . Gastroenteritis ▪ Spastic bowel
Influenza-like infections ▪ Antibiotic-induced diarrhea

Lomotil helps get children with diarrhea off toast and tea and back to normal diets and normal activity with gratifying dispatch. ▪ Lomotil lowers intestinal motility and permits absorption of excess fluid. This usually controls diarrhea promptly. ▪ Moreover, lowered intestinal motility achieved with Lomotil often relieves the abdominal cramps and discomfort so distressing to children.

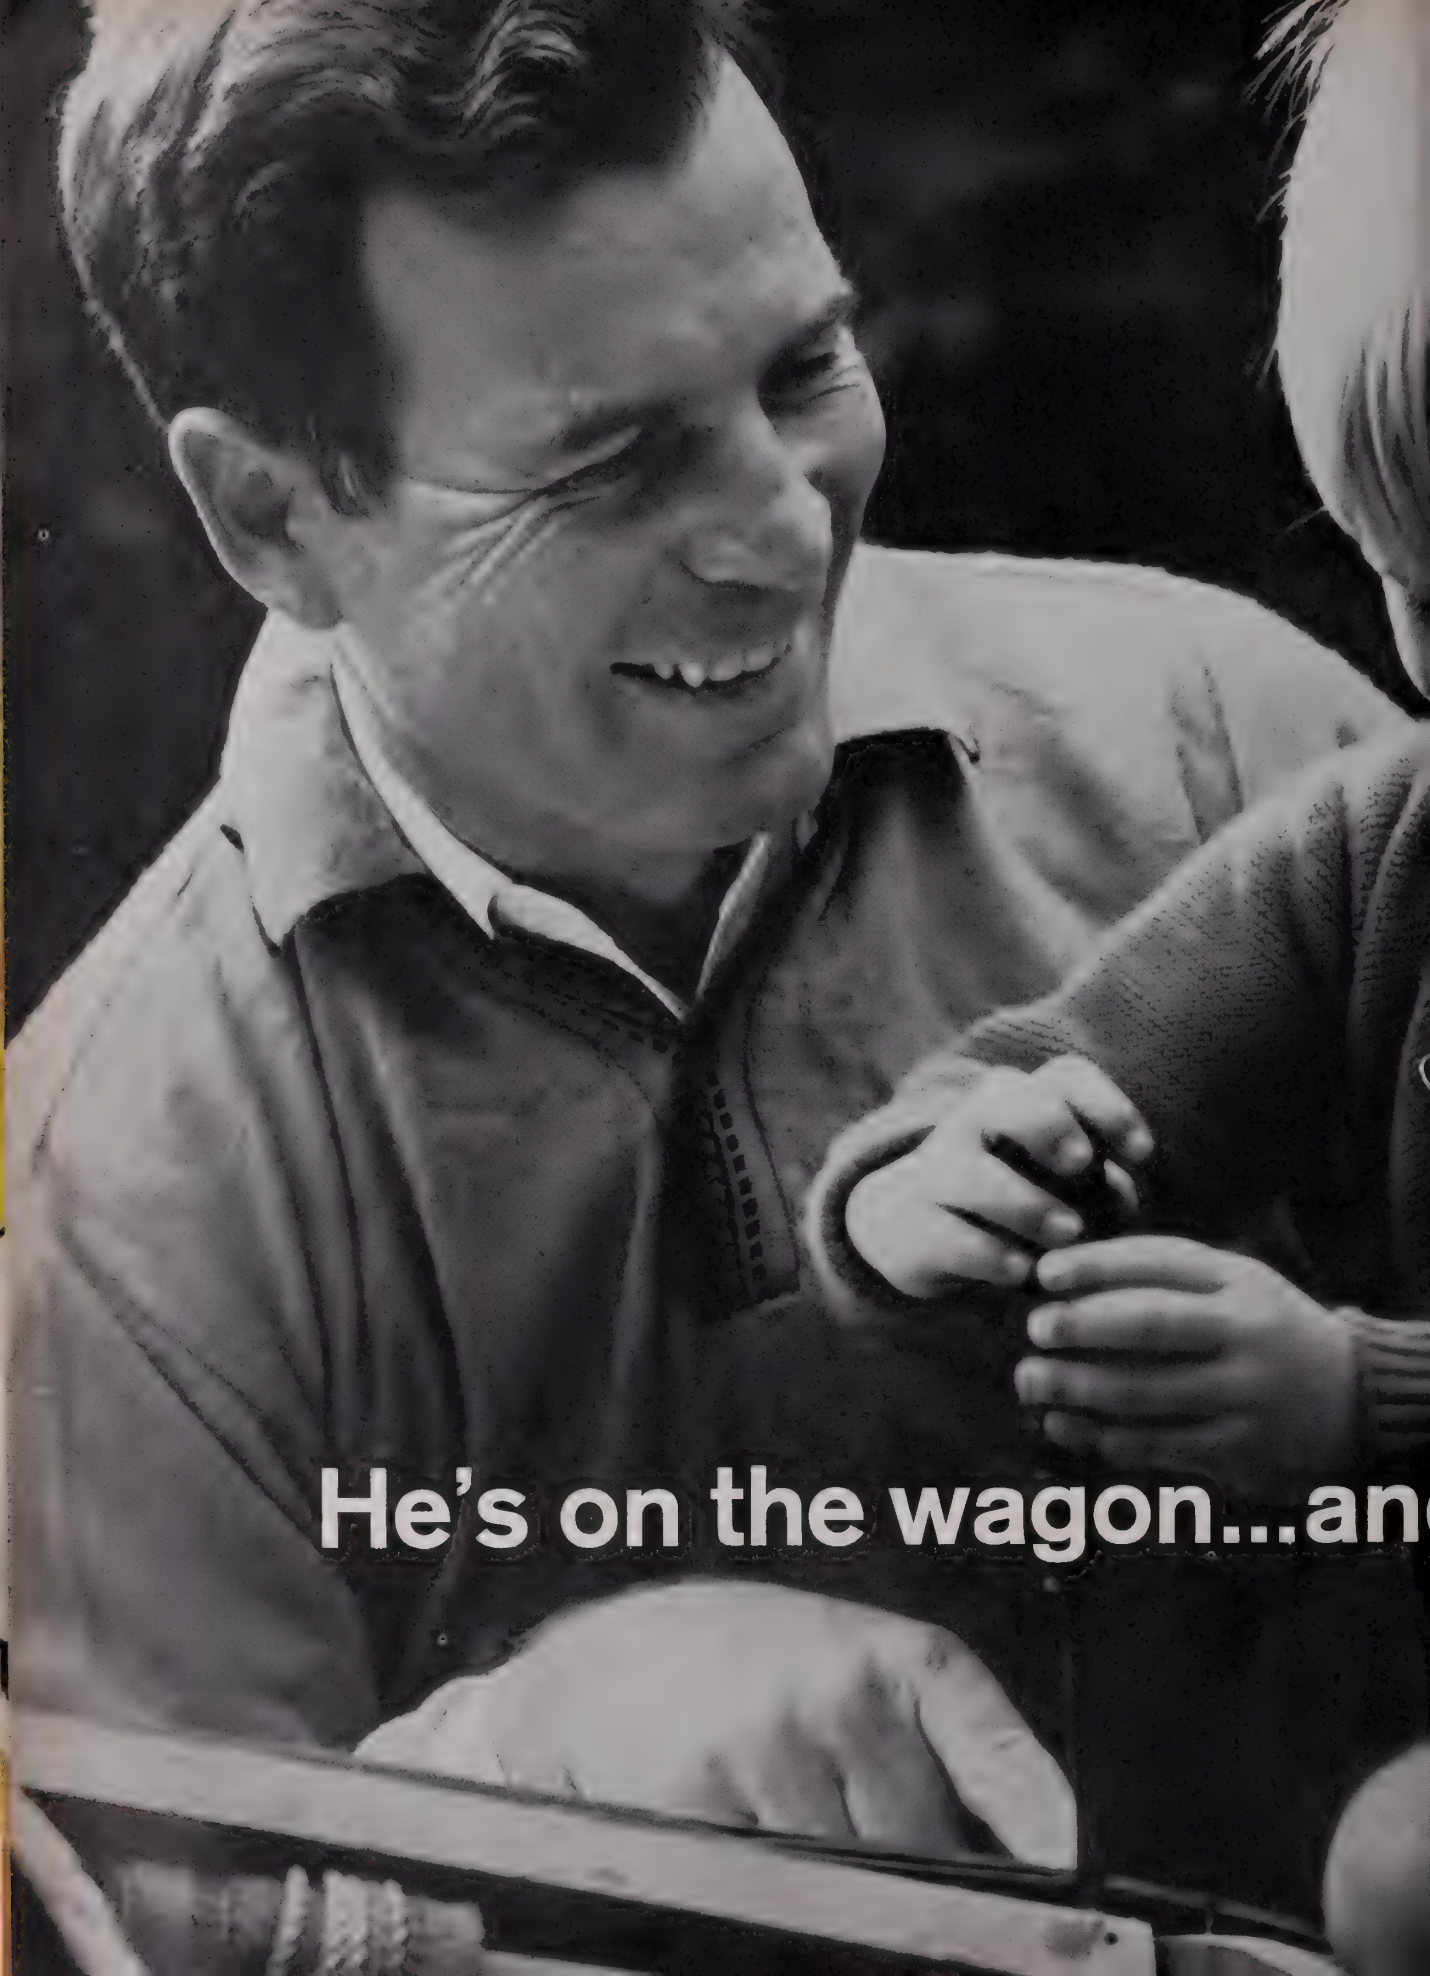


Precautions: Lomotil is a Federally exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded, and medication should be kept out of reach of children. Should accidental overdosage occur signs may include severe respiratory depression, flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia; continuous observation is recommended. Lomotil should be used with caution in patients with impaired liver function or those taking addicting drugs or barbiturates.

Side Effects: Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness, insomnia, numbness of the extremities, headache, blurring of vision, swelling of the gums, euphoria, depression and general malaise.

Dosage: The recommended initial daily dosages, given in divided doses until diarrhea is controlled, are:

Children: Total Daily Dosage



3-6 mo. . .½ tsp.* t.i.d. (3 mg.)
6-12 mo. .½ tsp. q.i.d. (4 mg.)
1-2 yr. . . .½ tsp. 5 times daily (5 mg.)
2-5 yr. . . .1 tsp. t.i.d. (6 mg.)
5-8 yr. . . .1 tsp. q.i.d. (8 mg.)
8-12 yr. . .1 tsp. 5 times daily (10 mg.)
Adults: . .2 tsp. 5 times daily (20 mg.)
or 2 tablets q.i.d.

*Based on 4 cc. per teaspoonful.

Maintenance dosage may be as low as one-fourth the initial daily dosage.

SEARLE *Research in the Service of Medicine*

He's on the wagon...an

How well does Vistaril relieve the symptoms that plague an alcoholic during the recovery period? Doctors Knott and Beard of the Alcoholic Rehabilitation Unit, Tennessee Psychiatric Hospital and Institute, recently conducted a double-blind study comparing Vistaril and another well-established antianxiety agent with placebo in 60 chronic alcoholic patients.[1]

The investigators conclude: "It was the opinion of the staff that hydroxyzine was generally more effective than chlordiazepoxide, for the following reasons: hydroxyzine was equally if not more effective in reducing anxiety and tension and it produced less daytime sedation...."[1] (See results on succeeding pages.)

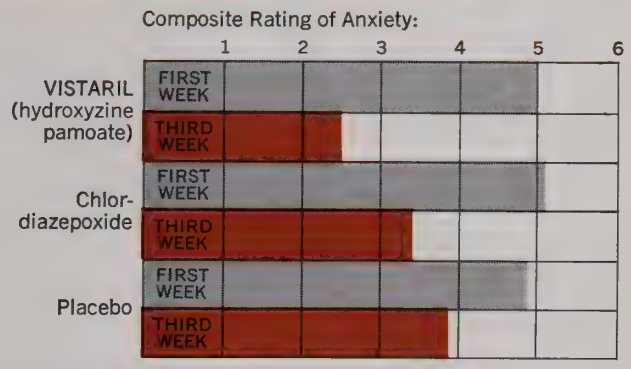
Here is new evidence that Vistaril can ease tension, allay anxiety in chronic, hospitalized alcoholic patients. *But you might also choose Vistaril for what it doesn't do.* Although not evaluated in this study, Vistaril is reported to be non-euphoriant, and its low toxicity makes it relatively safe. Best of all, Vistaril is non-habituating. To date, after more than ten years of clinical use, there have been no reports of dependency in patients receiving Vistaril.

With Vistaril, it is as easy to stop therapy as it is to start.

Vistaril®
(HYDROXYZINE PAMOATE)

the study: Sixty chronic alcoholic patients were hospitalized and randomly assigned to one of three oral double-blind treatment regimens for three weeks. Twenty patients received hydroxyzine (Vistaril®), 100 mg. q.i.d.; twenty others were given chlordiazepoxide, 25 mg. q.i.d.; and the remaining twenty received placebo capsules q.i.d. The capsule code was not made known until after completion of the study and analysis of the data. Response was measured with a modification of the Brief Psychiatric Rating Scale as originally outlined by Overall and Gorham.* Subjects were rated daily by trained staff members.

SYMPTOM RATING KEY



1=Not Present	4=Moderately Severe
2=Mild	5=Severe
3=Moderate	6=Extremely Severe

The figures which are given below represent the composite conclusions of the staff based on daily ratings during initial and final weeks of the study.

Vistaril®

(HYDROXYZINE PAMOATE)

BRIEF SUMMARY

Contraindications: Hypersensitivity to hydroxyzine. The parenteral solution, for intramuscular or intravenous use, *must not* be injected subcutaneously or intra-arterially.

Hydroxyzine, when administered to the pregnant mouse, rat, and rabbit induced fetal abnormalities in the rat at doses substantially above the human therapeutic range. Clinical data in human beings are inadequate. Until adequate data are available to establish safety in early pregnancy, hydroxyzine is contraindicated during this period.

Precautions: Hydroxyzine may potentiate the action of central nervous system depressants such as narcotics and barbiturates. In conjunctive use, dosage for these drugs should be decreased, as much as 50%. Because drowsiness may occur, patients should be cautioned against driving a car or operating dangerous machinery. The usual precautions for intramuscular injection should be followed; soft-tissue reactions have rarely been reported when proper technique has been used. Hydroxyzine parenteral solution for intramuscular use should be injected well within the body of a relatively large muscle. In adults, the preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus), or the mid-lateral thigh. In children, preferably the mid-lateral muscle of the thigh. In infants and small children the upper outer quadrant of the gluteal region should only be used when necessary, as in burn patients, in order to minimize the possibility of damage to the sciatic nerve. The deltoid area should be used only if well developed, such as in certain adults and older children, and only with caution to avoid radial nerve injury. Injections should not be made in the lower and middle thirds of the upper arm. Aspiration should be done to help avoid intravascular injection. On reported intravenous injection a few instances of digital gangrene have occurred distal to the injection site, considered to be due to inadvertent intra-arterial injection or possibly periarterial extravasation. Therefore, particular caution (aspiration and site injection) should be observed to insure injection only into intact veins; avoid either intra-arterial injection or extravasation. Intravenous administration should be accomplished slowly, no faster than 25 mg. per minute, and not to exceed 100 mg. in any single dose. In order to avoid possible adverse effects it is recommended that hydroxyzine parenteral solution be diluted to at least 50 cc. with sterile normal saline and administered over a period of four minutes or more, preferably into the tubing of a running intravenous infusion.

Adverse Reactions: Drowsiness may occur; if so, it is usually transitory and may disappear in a few days of continued therapy or upon dosage reduction. Dryness of the mouth may occur with higher doses. Involuntary motor activity, including rare instances of tremor and convulsions, has been reported, usually with higher than recommended dosage.

When this product is given intravenously undiluted, minimal amounts of intravascular hemolysis occur at the site of injection. Giving the maximum recommended intravenous dose (100 mg.) to adults results in immediate transient hemolysis with the liberation of a total of 2-3 grams of hemoglobin, which, in some individuals, can cause small amounts of hemoglobinuria. This compares with the normal red cell destruction from which approximately 8 Gm. of hemoglobin are liberated every 24 hours. If the hydroxyzine is diluted with 50 cc. of normal saline and given during a period of four minutes or more, this phenomenon does not occur.

Supply: Vistaril (hydroxyzine pamoate) Capsules: Equivalent to 25 mg., 50 mg., 100 mg. hydroxyzine HCl. Vistaril (hydroxyzine pamoate) Oral Suspension: Equivalent to 25 mg. hydroxyzine HCl per 5 cc. teaspoonful. Vistaril (hydroxyzine HCl) Parenteral Solution: 25 mg./cc.—10 cc. vial and 50 mg./cc.—2 cc. and 10 cc. vial; Isoject,® 25 and 50 mg. per cc., 1 cc. per unit.

Night Leg Cramps . . . Unwelcome Bedfellow

In Diabetes[1], Arthritis[2], and Peripheral Vascular Disorders[2]

now . . . specific therapy for night leg cramps

Walker

QUINAMM™

Consistently effective, QUINAMM provided complete relief in 94% of 200 patients studied, many of whom were severe cases refractory to other medication.[3] Your prescription for one tablet at bedtime often controls painful night cramps with the initial dose . . . helps restore restful sleep.

THE NATIONAL DRUG COMPANY
DIVISION OF RICHARDSON-MERRELL INC
PHILADELPHIA, PENNSYLVANIA 19144

Prescribing Information: Composition: Each white, beveled, compressed tablet contains: Quinine Sulfate 260 mg. and Aminophylline 195 mg. **Contraindication:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Porphyria*

THE DRAMATIC effect of confirming the diagnosis of porphyria by the finding of abnormal amounts of porphyrins or porphyrin precursors, or both, in the blood, urine, or stool has increased the clinical interest in this relatively rare metabolic disorder. The patient with acute intermittent porphyria who presents variations in the triad of classic findings consisting of recurrent colicky abdominal pain, psychic disturbances, and peripheral neuropathies has, at times, confounded even the most astute internist, neurologist, or surgeon. Unusual combinations of findings occurring in the patient with acute intermittent porphyria, as reported by Shuman and Snively,[1] demonstrate the importance of considering altered porphyrin metabolism as being responsible for varied and unusual combinations of symptoms.

Dermatologists have long been interested in another form of the disease, namely porphyria cutanea tarda.[2] In this condition, various photosensitive or blistering dermatoses have been considered as causes of such reactions because the skin of the sun-exposed areas of the hands and forearms, face, and neck are readily susceptible to trauma and blistering. Among these dermatoses are included epidermolysis bullosa, hydroa aestivale,** bullous impetigo, erythema multiforme, and drug reactions.

Secondary changes, such as suffusion of the face and upper trunk, scleral injection, ulceration, scarring sclerosis, and hyperpigmentation of the skin, usually permit ready clinical diagnosis of porphyria cutanea tarda. At times, milia, hirsutism, and darkening of the hair, or all of these, add confirmatory evidence to the diagnosis. A degree of liver dysfunction is usually present.

Some drugs can precipitate or cause a recurrence of porphyria cutanea tarda, as they do acute intermittent porphyria. Estrogenic preparations have been known to precipitate flares of acute intermittent porphyria, and overt signs of porphyria cutanea tarda can be seen in a middle-aged man who is taking estrogens as a part of therapy for carcinoma of the prostate.[3] The antimalarial drugs, used as anti-inflammatory agents in some diseases (lupus erythematosus and arthritis), also may precipitate a flare of porphyria.[4] Hexachlorobenzene,[5] which had been used as an antifungal agent in the treatment of wheat sent to Turkey, precipitated a form of porphyria characterized by severe mutilation of the skin and hirsutism and was referred to as Turkish porphyria.

Griseofulvin, a drug now commonly used in the clinical management of superficial fungous infections of the skin, was recognized as altering the metabolism of porphyria in mice.[6] Later, this same alteration was noted in patients with porphyria who were given this drug,[7,8] at times with exacerbations of their symptoms.

The presumption in the drug-exacerbated

For the taste you never get tired of.

porphyrias is that in some manner these drugs interfere with the biosynthesis of heme, with the production of the porphyrin products characteristic of the particular clinical type of the disease. For example, Levere,[9] after the finding of increased levels of aminolevulinic acid synthesis in chemically induced hepatic porphyria, demonstrated increased levels of this same rate-limiting enzyme in a patient who had signs of porphyria cutanea tarda while receiving diethylstilbestrol.

As the details of porphyrin metabolism have become known, some diseases previously considered "idiopathic" are now recognized as being associated with altered porphyrin metabolism. These include solar urticaria,[10] eczema solare,[11] and hydroa aestivale,[12] all of which are associated with protoporphyrin.

Cesarean Hysterectomy

THERE HAS been controversy in recent years concerning the advisability of cesarean hysterectomy replacing cesarean section with tubal ligation for sterilization. Janes, Smith and Williams* elsewhere in this issue in a series of 25 cesarean hysterectomies have shown that significant complications occur. Excessive blood loss and bladder injury are the most frequently encountered. Bladder injury led directly to one death. It must be emphasized that seven hysterectomies were performed as life-saving procedures and five patients had malignant disease. Another two patients had impending intrauterine infection, and hysterectomy or extraperitoneal cesarean section may have been mandatory. In considering the role of cesarean hysterectomy for sterilization these 14 cases must be excluded.

Seven patients had uterine myomas or congenital anomalies and, although sterilization was a likely consideration in these cases, it was only the remaining four patients with defective uterine scars whose pelvic pathology would not present problems in the nonpregnant state. It is this small group which must be compared with cesarean section and tubal ligation. Nevertheless, the added risk of complications associated with removal of the normal uterus, although admittedly small, is probably not justified as an elective procedure even when balanced against the one to two percent probability of cancer of the cervix developing in the subsequent 50 years.[1]

The patient with pelvic pathology may have a definite indication for hysterectomy, but since cesarean section is frequently unscheduled, it is usually best to perform the definitive surgery at a later time when conditions are optimal.

treat one . . . six people benefit

The brunt of senility falls on the family as much as the patient. But usually within one or two days, 'Thorazine' can control senile anxiety and fear . . . dispel the confusion shown by nighttime wandering and chattering . . . restore appetite and interest in personal grooming. Treat the senile patient with 'Thorazine'—the whole family can benefit.

Before prescribing, see complete information, including adverse effects reported with phenothiazines and symptoms and treatment of overdosage, in SK&F literature or *PDR*. The following is a brief precautionary statement.

Contraindications: Comatose states or the presence of large amounts of C.N.S. depressants.

Precautions: Potentiation of C.N.S. depressants may occur (reduce dosage of such agents when used concomitantly). Use with caution in patients with chronic respiratory disorders. Antiemetic effect may mask overdosage of toxic drugs or obscure other conditions. Administer in pregnancy only when necessary. Because of possible drowsiness use cautiously and warn patients who operate vehicles or machinery.

Adverse Reactions: Drowsiness; dry mouth; nasal congestion; constipation; amenorrhea; miosis; mild fever; weight gain; hypotensive effects, sometimes severe with I.M. administration; epinephrine effects may be reversed; dermatological reactions; parkinsonism-like symptoms on high dosages (in rare instances, may persist); lactation and moderate breast engorgement (in females on high dosages); and less frequently, cholestatic jaundice (use cautiously in patients with liver disease). Adverse reactions occurring rarely, include: mydriasis; agranulocytosis; skin pigmentation; epithelial keratopathy; lenticular and corneal deposits (after prolonged substantial doses).

Available: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg.; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg.; Injection, 25 mg./cc.; Syrup, 10 mg./5 cc.; Suppositories, 25 mg. and 100 mg.

Episodic Vertigo

In few conditions encountered in the practice of medicine is the etiologic diagnosis more difficult than that of episodic vertigo. Dr. Williams'* plea that we seek the specific cause for each case of episodic vertigo is of extreme importance for the success of the treatment, especially if one of the many surgical procedures is to be considered. Failure is certain if an unnecessary or inappropriate operation is performed. It follows that, in order to make an accurate diagnosis, every patient with episodic vertigo should have a thorough neuro-otologic examination with special attention to the history. Minimally, the tests should include audiography for pure-tone and speech discrimination, caloric vestibular tests (preferably by electronystagmography), and roentgenograms of the temporal bones. These examinations are relatively inexpensive and far less difficult to interpret than the electrocardiogram which is now routinely included in any thorough cardiac examination.

Should the vestibular and audiometric tests indicate a specific region of involvement, more extensive audiometric examination may be done. Intracranial disease likewise requires specific testing: for example, roentgenologic study with contrast medium for tumors of the cerebellopontine angle, cerebrospinal fluid electrophoresis for multiple sclerosis, electroencephalogram for temporal lobe brain abscess, or electronystagmography to detect directional preponderance for brain-stem viral encephalitis. A trial of anticoagulants may be the only way a diagnosis of basilar artery insufficiency may be confirmed; or a trial of diphenylhydantoin (Dilantin) to relieve the attacks of vertiginous epilepsy may be necessary.

As Dr. Williams points out, the most common cause of episodic vertigo seems to be a stimulus affecting the righting reflexes in the head or neck. We see such patients with cervical spondylitis, sprained cervical muscles, and cervical injury. Although we have no treatment which will immediately cure these disorders, symptomatic treatment to the neck and the use of antivertiginous drugs will often give relief.

With a careful analysis of every patient and the development of greater knowledge about the cause of vertigo, it is hoped that fewer patients will have a diagnosis of psychogenic vertigo or a nonspecific diagnosis, such as "Meniere's syndrome."

Communication Disorders in Children

"Deafness in Young Children" by John E. Bordley,* M.D., Professor of Otolaryngology at Johns Hopkins University School of Medicine, covers more than inability to hear. The broad concept of communication disorder, rather than the narrow concept of hearing disorder, should be considered when training or treating the child whose ability to communicate is delayed.

Hearing is an important part of communication, and indeed without hearing, the child develops verbal language skills only after much hard work by both the child himself and his teacher; and at best, these skills are limited in scope and are of poor quality. At the same time, factors other than deafness may contribute to the delayed development of language. These are mental retardation, brain damage, and some forms of aphasia. One can-

If hypothyroidism leaves your patient feeling like this...

consider

LETTER®

(SODIUM LEVOTHYROXINE, ARMOUR) TABLETS

Synthetic Thyroid Replacement Therapy

Letter® provides all the advantages of the synthetically pure chemical sodium levothyroxine. Dosage is precise and potency is consistently uniform.

and

Letter® is micronized to provide maximum opportunity for full absorption and clinical response.

In addition Letter® is distinctively color coded with an identifying number stamped on each tablet to provide accurate dosage control.

Indications: Hypothyroid conditions. **Contraindications:** Thyrotoxicosis, acute myocardial infarctions unless associated with hypothyroidism. In hypothyroidism with hypoadrenalism coadministration of corticoids with LETTER® is recommended. **Precautions and Side Effects:** Excessive dosage may result in diarrhea, cramps, palpitation, nervousness, rapid pulse, sweating. If symptoms appear, discontinue medication for several days, then reinstitute at a lower level. Since myxedema patients with heart disease may suffer seriously from abrupt increases in dosage, caution should be exercised in adjusting dosage. **Dosage:** Generally, the initial adult dosage is 0.1 mg. daily. This may be increased in small increments every one to three weeks until proper metabolic balance is achieved. **Available:** Bottles of 100 tablets, in six potencies: 0.025 mg. (violet), 0.05 mg. (peach), 0.1 mg. (pink), 0.2 mg. (green), 0.3 mg. (yellow), and 0.5 mg. (white).

ARMOUR PHARMACEUTICAL COMPANY • CHICAGO, ILLINOIS

not assume that delayed language development is the result of any one of these factors, and the child who does not develop normal communication patterns should be studied in sufficient detail to determine which of the several possible defects is the cause of the delay. Only with such knowledge can an appropriate system of training or treatment be developed. Doctor Bordley's paper covers this field with clarity and comprehension. It should be of great value to all physicians who deal with children.

Neoplasia of the Parotid Gland*

PAROTIDECTOMY—EITHER subtotal or total—is the surgical procedure of choice in the management of tumors of the parotid gland. These lesions should not be enucleated or excised; and the facial nerve should be sacrificed, in part or totally, only when a malignant tumor involves the nerve or a portion of it.

Commonly the parotid gland was spoken of as a bilobar structure—a superficial lobe and a deep lobe connected by an isthmus, with the facial nerve going around the isthmus. However, Winsten and Ward** proved that the gland is a unilobar structure, with the facial nerve and its branches transgressing the gland and dividing it into a superficial part and a deep part.

The facial nerve is very consistent in its relationship to adjacent anatomic structures as it leaves the styloid foramen and projects beyond the parotid gland at its periphery. The safest surgical approach to the facial nerve is for the main trunk to be identified immediately medial and deep to the mastoid process in the substance of parotid gland. The dissection can then be carried peripherally. To identify peripheral branches and carry the dissection proximally is time consuming and hazardous.

If function of the facial muscle is to be preserved (when indicated) and the results of treatment are to be the best for the individual patient, parotid surgery should be done only by surgeons who are well trained and experienced in the techniques of parotidectomy.

You May Be Right

I was happy to hear that you had selected some quotes from my book, "Birth Control and Conscience," to appear in the Book Review Section* of MINNESOTA MEDICINE.

In recent years I have realized that (figuratively speaking) the government is watering the weeds in the garden of human life, and is thereby aiding these weeds to multiply as never before. Since the weeds tend to crowd out the useful plants, the situation has some resemblance to a cancer.

Public opinion is encouraging the multiplication of these human weeds on the basis of conscientious good intentions which favor unconditional charity to those who are hereditarily weak or weak-minded. I, of course, favor help to these people provided they do not pass their heredity on to future generations in excessive amounts.

M. H. Mothersill, M.D.
Minneapolis, Minnesota

*See Minnesota Med 50:1911, 1967.

Without doubt, Medicare, used properly, can benefit the elderly indigent; but so can the Kerr-Mills Act. Now that Medicare is a law, we must deal with the future as well as with the present. Of course, no one can foretell the future; however, not only the cornerstone, but also the entire foundation has been laid to project into the future many possible and highly probable provisions of this act.

Many proponents of Medicare feel that dealing with the fiscal intermediary is analogous to dealing with the local facility. Little do they realize that projected into the future is the provision that every medical and dental office will be required to submit all its bills to the fiscal intermediary. We shall have no choice!

How will our government enforce this provision? Our hospitals are now billing the fiscal intermediary; many staffed M.D.s are doing likewise. The government's next step will be to issue an ultimatum to our hospitals to the effect that the government will not allow the fiscal intermediary to issue funds to the hospitals, unless all of the M.D.s on the staff will accept assignment. This has already been programmed for a scheduled release date!

Now, you may say, "What's so bad about that? We are guaranteed 80% of our fees." This is correct; but please note that "fees" is the key word. What are fees? Are they ordinary and customary? They will be, up to a point. When this point has been reached our beneficent government will say, "Look, boys, your fees are not realistic, and we shall therefore determine what shall be a customary fee." We all know that prior to the inception of Medicare our welfare fees were extremely archaic. Are we going to regress to that era now—especially in view of the greater expansion of our present medical practices? Will it also be mandatory that we use generic medicine,

some of which we have seen quite intact in the stools of our patients because of non-absorption?

Never before in the entire history of our nation did a bill invoke so much oppositional mail as did the Medicare bill. Nevertheless, this bill was inaugurated with great fanfare. Statements bordering on prevarication were released to the press. Propaganda such as we have never before seen now accompanies this act as it mushrooms like an atomic bomb. This law, like an atomic bomb. will encompass, and engulf, every individual in the medical profession.

Thus far there has not been an analytical statement of the cost or of the "benefit" of Medicare. From published literature we can quite safely assume that what Medicare recipients receive is basically incommensurate with their contributions.

In summation: the entire medical profession will be subjugated to governmental directives, procedures, reams of paper work and red tape unless we protest, not only as a group, but also as individuals. Protest to your county, state, and national academies as well as your county, state, and national representatives. In the case of welfare recipients, let the governmental agencies collect solely from each other. Let us keep our direct billing. As far as our regular Medicare patients are concerned, I believe you will find most of them completely honest; the elderly who come to our Clinic are very conscientious about paying us and do not want us to wait until they receive government remuneration. These people directly oppose Medicare but do not know what they can do about it. Advise them to write to their legislators and congressmen. Tell them also to write to the governor of their state.

Let's make this a campaign which will again give the people of this nation a voice in their government.

Cults and Quackeries

Of all the nations of the world, the United States is most afflicted by its healers. Besides those holding the degree M.D., signifying doctor of medicine and, nowadays, some seven years of study following high school graduation, a host of queer practitioners pervade the medical field. . . . Cult follows cult and quackery succeeds quackery, frequently with amazing rapidity. . . . A complete picture of the farcical scene would require endless research. The United States unquestionably bears the palm in every class so far as healing cults are concerned.

A cult is "excessive devotion to some person, idea, or thing, especially when pursued as an intellectual fad by a body of enthusiastic, self-constituted admirers." As applied particularly to medicine, a "sectarian" is one who in his practice follows a dogma, tenet, or principle, based on the authority of its promulgator to the exclusion of demonstration and experience.

The cults may be classified easily into mental healing cults, mechanical cults, electric cults, nature cults and similar divisions, since they adhere definitely to such single devices. Other cults may be classified as merely non-medical, since they deprecate the use of medicaments.

The complacency with which cultist leaders dispose of the fundamental facts of science in promoting their views may be taken as sound evidence of their essential eccentricities.*

Post Seasons Greetings

Kevin is a Hippie

Each year when the frost is off the pumpkin and the last trixertreat has been served for dessert, I sit down and write an inventory of family achievement. I take it to the printshop and have several hundred copies knocked out and then, with a sense of accomplishment and Christmas spirit, I send these letters to all points east and west. This is our family's Christmas Letter. After checking the galley proofs of our 1967 letter, and being a veteran of some ten years in my family's service, I decided that I had arrived at a point where I might be of aid as an instructor to individuals who will be entrusted with the task of composing their family's 1968 Letters.

As most of you are aware, the Christmas Letter is a relative newcomer on the scene of American letters. This hastily-written, carbon-smudged greeting captured the fancy of millions of us who saw in it the very medium for conveying to our distant friends not only that we lived but that we lived darned well and deservedly so.

The goal of the Christmas Letter author should be to set up his family as a tightly-knit group of well-adjusted, forward-thinking, public-spirited overachievers, moving with the sure-footedness of a Grand-Canyon mule from December to December.

Some cardinal points to remember are that honesty is often brutality, no one loves a failure, and "weep and you weep alone." One should strive for modesty and good taste in exposition: not, "John had a whale of a year; it looks as if we'll clear fifty grand!" but, "John has really worked much, much too hard."

When selecting which of the many accomplishments and honors to stress, it is well to bear in mind that some attainments rate higher than others in affecting a really fine family image. They could be listed roughly in the order of importance:

1. Fulbright Scholarships
2. Students obtaining admission to the college of their choice.
3. American Fields Scholars: (Always referred to as AFS Students) "Mary had a most meaningful summer as an AFS student in Yucatan."
4. Some connection with the diplomatic service or an occupation with an international flavor: "Marge was just a teeny bit lonely as the family kept the home fires burning while Roswell was in New Delhi on the President's Survey of Far Eastern Economics and Cultural Developments in the Plumber's Helpers Market."
5. A new step up for the bread-winner: "Weldon has really been burning the candle at both ends since being made VP at International last April—you wouldn't believe the mess he inherited."
6. A European trip: "This time we rented a car and just loafed our way along seeing the things that we really wanted to see—the Basque country, the little English villages, Irish pubs—we arrived in Donegal just three days after Jackie had been there."
7. A wedding: "Of course they will live in an apartment until Spencer gets his Ph.D., but that's all to the good, since Iris will be writing her thesis and won't have time yet for housekeeping in the grand manner."

"All Interns are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.

8. New baby: "Honestly, we would never have believed what an utter joy it could be."
9. Skiing trips: "We feel that the family never actually got to know each other before—the doctor says that Morty's cast can come off on the 5th day of July."
10. Self-improvement courses: "Emily will be our spokesman when we get to Guadalajara. The instructor says he has never seen anyone with such a flare for languages."
11. Community Service: "Of course it's just plain hard work, but Harold can be justly proud that the Fifth District went over the top months before any other."

That should be a fair sampling.

Life being what it is, however, perhaps the greatest effort the Christmas Letter author will have to exert will lie in the area of what I call "interpretation." So I will set forth here some representative facts and their constructive interpretation.

Fact	Interpretation
Kevin is a Hippie.	Kevin, our young individualist, is a student at Berkeley. He is majoring in Political Science and Chinese Lute Playing. His professors feel that he shows marked freedom of thought and expression.
Roger did not get the Fulbright hinted at in last year's Christmas Letter.	Roger rather surprised us with his maturity. He feels that nothing is to be gained from an Ivory Tower attitude towards Education. He has very wisely accepted a position as head of the History Department at Podunk Junior Elementary School.
Mother did not win the School Board Election.	Even before the returns were counted we held a family council and unanimously decided that regardless of the outcome Mother's place is in the home. We feel that all too many wives and mothers are away from home during these invaluable formative years.
Junior flunked sixth grade.	We decided to hold Junior back a year. The school counselor thoroughly agreed with us. "Too many parents," he said, "are pressuring their children these days. If more parents had your courage and understanding . . ."
Eloise eloped at seventeen.	. . . a darling boy from a lovely family. Both he and Eloise are so mature for their years. There's such a difference in the maturation of children, don't you think?
Father lost his job.	We've always dreamed of John's taking a sabbatical. This year we just decided to take the bull by the horns. There are so many things he's always wanted to do. Maybe this year is the year to write The Book.

The Christmas Letter should finish on a note of restrained humility and well-bred religious feelings: "We are truly thankful that this Blessed Season

ASSURANCE COMPANY

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl®-1.

(norethindrone 1mg. & mestranol 0.05mg.)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Prescribing Information

Contraindications: Patients with any symptoms or history of thrombophlebitis, pulmonary embolism, liver dysfunction or disease, carcinoma of breast or genital organs, or undiagnosed vaginal bleeding.

Warnings: Discontinue medication pending examination if there is sudden partial or complete loss of vision, proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. The safety of Norinyl-1 in pregnancy has not been demonstrated. If a patient misses two consecutive periods, pregnancy should be ruled out before continuing the medication. If she has not adhered to the prescribed schedule, pregnancy should be considered at the first missed period. Active ingredients of oral contraceptives have been detected in the milk of mothers who received these drugs; the significance to infants has not been determined.

Precautions: Pretreatment physical should include examination of the breasts and pelvic organs, as well as a Papanicolaou smear. If endocrine or liver function tests are abnormal during therapy, repeat tests are recommended after the drug has been withdrawn for two months. Following administration of drug, preexisting uterine fibromyomata may increase in size. Careful observation and caution are required for patients with symptoms or history of epilepsy, migraine, asthma, cardiac or renal dysfunction, cerebrovascular accident, psychic depression, and diabetes. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. Possible long-term effects of the drug on pituitary, ovarian, adrenal, hepatic or uterine function must await further studies. The physician should be alert to the earliest manifestations of thrombophlebitis and pulmonary embolism. The drug should be used judiciously in those young patients in whom bone growth is not complete. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask symptoms of the climacteric. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

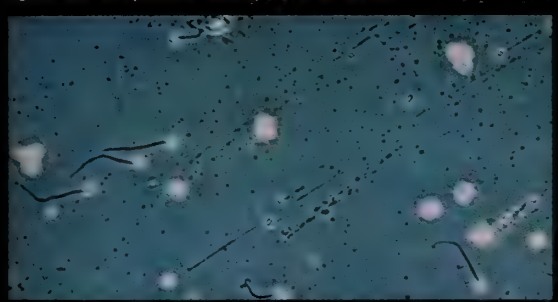
Side Effects: The following have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression. Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation posttreatment, premenstruallike syndrome, changes in libido, changes in appetite, cystitislike syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption, and itching. The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has neither been established nor disproved): thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory tests may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from

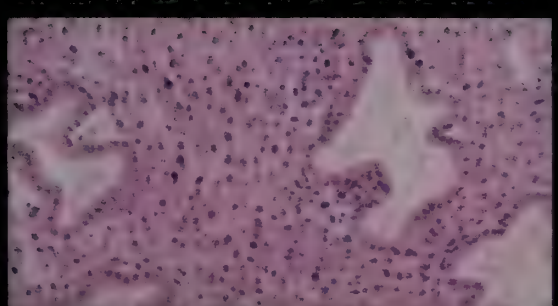
SYNTEX

LABORATORIES INC., PALO ALTO, CALIF.



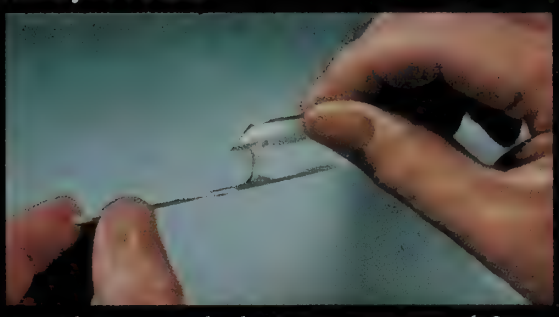
Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation. These effects are illustrated below.

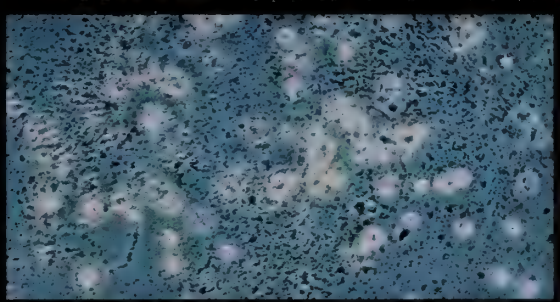


Untreated Patient

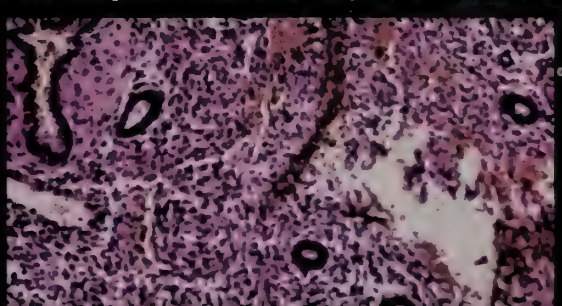
Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.



Spermatozoa appear healthy, active, freemoving.



Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.



Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.

Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl®-1 tablets
(norethindrone 1mg. & mestranol 0.05mg.)

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

An uncommon steroid for common inflammatory dermatoses

In everyday topical steroid therapy, Synalar produces rapid resolution of inflammation and itching in steroid-responsive dermatoses—and at relatively low cost to the patient.

Advanced molecular design enhances potency

Synalar combines the advantage of earlier corticosteroid compounds with unique structural innovations. As a result, preparations of Synalar 0.01% and Synalar 0.025% have been reported to be more potent topically and significantly more effective than hydrocortisone 1.0%. The unique fluocinolone acetonide molecule provides one of the most useful topical corticosteroids for everyday practice.

Impressive clinical results in a wide range of dermatologic problems

The clinical efficacy of Synalar has been extensively documented in the world literature. Commonly encountered diseases such as allergic and contact dermatitis, eczematous and seborrheic dermatitis, and neurodermatitis respond rapidly to Synalar, often where previous therapy with other topical corticosteroids has failed.

Low patient cost for wider usefulness

With Synalar, a high degree of efficacy does not mean high price. And—a small quantity goes a long way. Thus, your patients can often obtain the "economy" of a hydrocortisone preparation with the proved efficacy of a potent, truly advanced steroid.

Synalar®
fluocinolone acetonide

Turn page for contraindications, precautions and side effects.

For everyday topical steroid therapy

Synalar® 0.01%

fluocinolone acetonide provides economy in two practical dosage forms

For general use, the most economical and widely applicable concentration of Synalar is 0.01% Cream in a water-washable, vanishing cream base. Synalar Solution 0.01% is especially valuable in dermatoses involving moist, intertriginous areas or hairy sites where creams and ointments do not spread or penetrate readily. Synalar Solution is a unique dosage form—clear, nongreasy, cosmetically elegant.

Product Information

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. *Precautions:* Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. *Side Effects:* Side effects are uncommon with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. In such cases the agent should be discontinued and appropriate measures taken. *Availability:* Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Solution 0.01%—20 and 60 cc. plastic squeeze bottles. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

Curbstone Consultation

Hospital Laboratory

QUESTION: I am having trouble with the hospital laboratory. Today they claim to be unable to perform complement fixation tests for lues on one of my patients because his serum coagulates in the water bath at 56 C. What can be done about this?

ANSWER: This seemingly annoying complication during a routine laboratory procedure actually represents a great help in the diagnosis of this case. Coagulation at 56 C. establishes the presence of a pyroglobulin in the patient's serum. Pyroglobulinemia is found most commonly in multiple myeloma but occasionally in other protein disorders such as macroglobulinemia.

Sleep Disturbance in An Infant

QUESTION: Twice recently, shortly after retiring, I've been awakened by a call from two frantic mothers saying their children, aged 10 and 13 months respectively, had awakened from a deep sleep crying out in terror. "Would you come right over?" I did, only to find the children in each instance sound asleep! What's the explanation and what can the busy physician do to avoid such unwelcome calls?

ANSWER: No one yet knows fully why this phenomenon occurs, but it is not unexpected in children in this age range. The most logical explanation is that the child is carrying over unresolved tensions of the day into the night and he may be dreaming—a possibility which all too often is overlooked.

To avoid being called unnecessarily the physician can do two things: (1) he can discuss the possibility of such an occurrence with the parent and prepare him for its happening; (2) if it happens he can ask the parent to determine if the child (a) has a temperature, (b) is cold, (c) is hungry, (d) is wet or soiled. Provided everything is in order, the child should be thoroughly awakened, given comfort and reassurance for a while, and then placed in his crib, perhaps with a favorite toy. In the majority of instances the child will shortly resume his sleep. Parents should be discouraged from taking their children into bed with them under such circumstances. Inevitably this creates other problems.

The Viewing Box

Unusual Intra-Abdominal Calcification

This is a plain film of the abdomen obtained prior to exploratory laparotomy on a 30-year-old white male suspected of having intraperitoneal hemorrhage. He had suffered a deep stab wound in the left flank the evening of admission, but claimed to have been in excellent health all of his life prior to this episode. The abdominal films showed no visible free air or intraperitoneal fluid. At surgery a lacerated spleen was found and removed. The surgeon then correctly identified the obvious plain film finding of the right lower quadrant calcifications.

What is your diagnosis? (See next page.)

Figure

Diagnosis: Fecaliths in a Meckel's Diverticulum

A narrow-necked Meckel's diverticulum measuring 5 × 5 cm. was excised and found to contain five triangular-shaped stones which on subsequent section showed a soft fecal core. The diverticulum also contained a small focus of ectopic gastric mucosa and showed minimal chronic inflammatory changes.

In 1812 Meckel first described the entity as a true diverticulum, that is, one with a complete intestinal wall. The incidence of this diverticulum, which represents embryologic remnants of the yolk stalk and the omphalomesenteric attachment, is approximately 2% in autopsy and surgical material. It is seen three times as commonly in males as in females. The diverticulum is usually found one to three feet from the ileocecal valve on the antimesenteric side of the ileum, and most often is conical in shape with a wide mouth.

Many complications of a Meckel's diverticulum have been reported, such as peptic ulceration from heterotopic gastric mucosa, inflammation, intussusception, neoplasm, internal hernia, and volvulus. One of the rarest complications is coprolith formation. Even rarer is demonstration of the coprolith by x-ray.

Complications from the stones themselves have been reported, including hemorrhage, inflammation, and perforation with the stone lying free in the peritoneal cavity. Recently reported have been several cases of ileal obstruction distal to a diverticulum following passage of a stone that formed within it.

Diagnosis of this condition has been extremely rare, let alone the infrequent preoperative diagnosis of a diverticulum itself. With the use of barium studies and certain radiographic signs, Meckel's diverticulum might be diagnosed more often before the abdomen is opened. Certainly the finding of right lower quadrant calcifications, no matter what morphologic form they might have, should make one consider the possibility of stones within a Meckel's diverticulum. Lerner et al.[4] reported a calculus within a constant gas-filled pocket in the right lower quadrant. This should be highly suggestive of the diagnosis. When sought for, the diverticulum can often be outlined during the course of a barium meal study, occasionally showing an unexpected radiolucent stone as a negative filling defect. Bischoff and Stampfli[1] reported two cases of Meckel's stone in which the stones showed as a "ribbon-like" calcification which they thought might be characteristic.

To be included in the differential diagnosis of a right lower quadrant stone would be a coprolith in the vermiform appendix, or a stone in a low-lying gallbladder or a ptotic kidney.

Trauma Conference

Traumatic Rupture of the Testicle

BLUNT TRAUMA to the testicle resulting in rupture without an accompanying laceration of the scrotum has long been considered a rare event. Thirty-five cases have been reported in the literature to date.[3,18] This paper will discuss an additional case and will present a review of the literature.

Case Report

A 23-year-old active duty serviceman received a blow to his left testicle when he slipped and fell off a box. His initial pain was severe, and he was sent to a local hospital where he received conservative treatment consisting of scrotal elevation, ice packs to the scrotum, antibiotics, Chymoral and large doses of demerol with partial relief of symptoms.

Three days later he was transferred to the Minneapolis Veterans Administration Hospital. Initial examination revealed a swollen and painful left testicular mass which did not transilluminate along with ecchymotic areas on the penis and left side of the scrotum. The urine contained no red blood cells, and a number 16 Fr. Robinson catheter was easily passed through the entire length of the urethra. The remainder of the physical examination was normal except for a temperature of 100.2° F.

A preoperative diagnosis of either testicular rupture or torsion of the spermatic cord was made. Three days following admission, surgical exploration through a left scrotal incision was performed, revealing a 4.0 by 6.0-centimeter hematocele under tension (Figure 1). After the hematocele was evacuated, a 3.0-centimeter transverse laceration through the tunica albuginea with extrusion of testicular tissue was noted in the lower pole of the testis. The devitalized parenchymal tissue was debrided by sharp dissection. The tunica albuginea was then closed with interrupted 3-0 plain catgut sutures, and the scrotal incision was closed around a Penrose drain. The estimated reduction of testicular mass at surgery was 15 per cent. The postoperative course was uneventful.

A one-month follow-up examination revealed the left testicle to be of approximately normal size and non-tender, and the scrotal incision was well-healed.

Review of The Literature

The first reported case of traumatic rupture of the testis was by Cotton in 1906.[1] Since then additional cases have been reported.[2-10,13-18] McCormack[3] collected 27 cases and added five additional ones. No testicular disease was present in any of these cases prior to injury except in one case where a seminoma* was found to antedate the trauma.[8] No cases of ectopic testicular

*See Test Your Word Score Page 53.

rupture have been reported. More than half of the reported cases have occurred during participation in athletic events. Wesson[9] reported his experience with a case of traumatic rupture of a solitary testicle.

Most of the cases have occurred in patients less than 30 years of age with an age range of eight to 49 years. All patients have been younger than 50 years, substantiating McCrea's statement regarding the frequency of this injury being confined to the period of increased physical activity.[6]

It is the authors' personal conviction that this entity, along with undiagnosed torsion of the spermatic cord, may be far more frequent than has been reported, as evidenced by the large number of atrophic testicles found during routine physical examination. A more aggressive surgical approach, as recently recommended by a number of urologic surgeons, may show this to be the case.

Etiology

Contusions of the testicle are not an uncommon occurrence, but because of its shape and mobility in the scrotal sac and its tough inelastic capsule (tunica albuginea), a laceration of the testis is very rare. According to Wesson,[9] approximately 110 pounds of force is necessary to rupture the testis when the latter is caught between two unyielding objects. McCrea[6] feels that the blow must be delivered with a sudden compressing or crushing force and must be directed straight or obliquely upward in order to impinge the testicle between the pubic bone or thigh and the hard traumatizing object.

McCormack,[3] in two of his cases, questioned whether a missile traveling at moderate velocities might have caused the testicle hanging loose in the scrotum to literally explode on contact, although he did not rule out that the testis in these cases might have been forced against the pubis, permitting a crushing blow.

Pathology

The gross pathology of traumatic rupture of the testis includes:

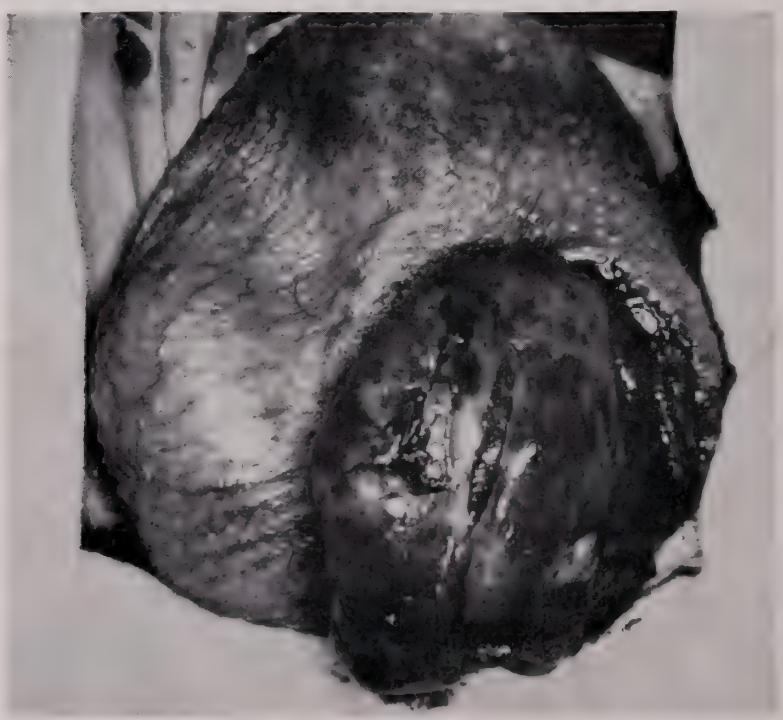

Fig. 1—Four-by-six centimeter hematocele surrounding the left testicle.

1. Ecchymosis and edema of the scrotum and contiguous areas.
2. Rupture of the visceral layer of the tunica vaginalis.
3. Hematocele with fresh blood or blood clots between the visceral and parietal layers of the tunica vaginalis.
4. Rupture of the tunica albuginea with resultant extrusion of testicular tissue which is usually devitalized. The tear is generally transverse; however, a longitudinal tear was reported by Dundon.[10]
5. Associated injuries of the epididymis, spermatic cord, penis, urethra or other testicle.

Signs, Symptoms and Diagnosis

The signs and symptoms following traumatic rupture of the testis are not distinct from those following other types of trauma, or from torsion of the spermatic cord, testicular tumors or inflammatory diseases such as epididymo-orchitis. In cases of traumatic rupture there may be pain, swelling, obliteration of the scrotal skin folds, ecchymosis, skin abrasions, nausea, vomiting, shock and fever.

Pain is usually present to some degree following the injury. It may be minimal to severe and may last from minutes to weeks. The scrotal swelling with resultant loss of skin folds is usually gradual. It seldom becomes excessive unless associated with further scrotal injury such as rupture of the spermatic cord. Occasionally when a patient is seen days or weeks following the injury, only a moderately enlarged epididymo-testicular mass is found, and a diagnosis of chronic epididymo-orchitis is mistakenly made. Ecchymosis along with abrasions of the scrotal skin is seen in most cases following the acute injury. These ecchymotic areas may extend onto the thighs, penis and perineum. Nausea, vomiting and shock have been reported following traumatic rupture of the testis; however, these have not been outstanding characteristics. Several patients with fevers ranging from 99° to 104° F. have been reported.[2-3]

The complications following traumatic rupture of the testicle are secondary infections, abscess formation and atrophy.[12] McCormack[3] has suggested the possibility of an auto-immune reaction to the patient's own extravasated sperm. Whether or not spermatozoa from extravasated testicular tissue actually act as antigens and cause the production of antibodies is not known.

Treatment

Treatment should be instituted as soon as possible when traumatic hematocele is suspected or diagnosed by needle aspiration of blood. Surgical exploration with evacuation of the hematocele and inspection of the testis, epididymis and spermatic cord should be undertaken promptly. If rupture of the testicle is found, the devitalized testicular tissue should be debrided and the defect in the tunica albuginea closed with interrupted horizontal mattress sutures of 3-0 plain catgut. The scrotal cavity is drained with a Penrose drain. Testicular rupture with total extrusion of testicular tissue may have to be treated by total orchiectomy. If, however, the tunica albuginea is not severely damaged or infarcted, the capsule might best be left in place, as in subcapsular orchiectomy, since the capsule has been shown to contain Leydig-like cells which are hormonally functional.[12]

Summary

Traumatic rupture of the testicle is rare. Only 36 cases including our own

have been reported in the literature. We feel that many cases of testicular atrophy found during routine physical examination are due to undiagnosed traumatic rupture of the testis or undiagnosed cases of spermatic cord torsion. We are also of the opinion that all cases of traumatic hematocele should be explored as soon as possible after the injury with the hope of salvaging more functional testicular tissue.

Avicenna* Cures a Melancholic

A certain prince was afflicted with melancholia and suffered from the delusion that he was a cow. Every day he would low like a cow, causing annoyance to everyone, and crying, "Kill me, so that a good stew may be prepared from my flesh"; until matters reached such a pass that he would eat nothing, while the physicians were unable to do him any good. Finally Avicenna, who was at this time acting as prime minister to 'Ala'u'd-Dawla ibn Kakuya, was persuaded to take the case in hand. First of all he sent a message to the patient bidding him to be of good cheer because the butcher was coming to slaughter him, whereat the sick man rejoiced. Some time afterwards Avicenna, holding a knife in his hand, entered the sick room, saying, "Where is this cow, that I may kill it?" The patient lowed like a cow to indicate where he was. By Avicenna's orders he was laid on the ground bound hand and foot. Avicenna then felt him all over and said, "He is too lean, and not ready to be killed; he must be fattened." Then they offered him suitable food, of which he now partook eagerly, and gradually he gained strength, got rid of his delusion, and was completely cured.**

Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.

SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.

ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q.* 4 *h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA SINUTAB® FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

Tumor Conference

Brotherly Lumps

Familial Occurrence of Chemodectoma

CAROTID BODY tumors are rare. Since Von Haller first described the carotid body in 1743, slightly over 500 tumors of that body have been reported. One of the side effects of their treatment is that it usually induces an uncontrollable desire to write in the surgeons who remove these tumors. It is possible we could have resisted had this not been a well confirmed familial occurrence.

Case Report

A 43-year-old white male sheetmetal worker was admitted to the Neurology Service of the Minneapolis Veterans Administration Hospital because of increasing difficulties in performing routine work. He complained of bifrontal headaches and difficulty remembering measurements in sheetmetal lay-outs.

The past history revealed the following positive findings: (1) Appendectomy in 1942, (2) Pilonidal cystectomy in 1949, (3) A left neck mass first noted while in the Navy in 1958 and slowly increasing in size, (4) Herniated nucleus polyposis in 1961, (5) Unroofing of a perirectal abscess in 1961.

Physical Findings

The patient was a well-muscled white male with mild bilateral exotropia with ptosis of the left eyelid and anisocoria,* the left pupil being smaller than the right. There was a 5 x 4 x 4 cm. mass in the left neck that transmitted a carotid pulse. The mass was prominent and easily palpable bimanually in the pharynx. The rest of his physical examination was within normal limits.

Laboratory Findings

Complete blood count and urinalysis were normal and the VDRL was negative. The 24-hour RAI 11%, alkaline phosphatase 11.2, serum creatinine 1.2, protein-bound iodine 8.3, calcium 9.7 mgm.%., phosphorous 3.8 mgm.%., CO_2 combining power 26.5 mgm.%., chlorides 105 mgm.%., sodium 142 mgm.% and potassium 4.6 mgm.%.

Chest x-ray, skull x-rays, brain scan and electroencephalogram were all normal. The thyroid scan was normal without any uptake over the left lateral neck mass.

A left carotid angiogram clearly demonstrated the extremely vascular mass in the left neck at the level of C2-C3 (Figure 1). A compression angiogram revealed excellent filling of the right cerebral vessels from the left, showing good circulation cross-over.

Operation

On the basis of the physical findings and the angiographic picture the patient had an exploration of the left neck. The carotid vessels were isolated above and below the carotid body tumor (Figure 2). Precautionary preparation for an intravascular shunt

*See Test Your Word Score Page 53.

was made but not required in the dissection. This tumor was excised by subadventitial dissection. The internal carotid artery was narrowed where compressed between tumor and the mastoid process. When undistended with blood the chemodectoma measured 3.5 x 2.5 x 2 cm. The histologic picture is shown in Figure 3. Postoperatively, the patient did well except for pain in the upper portion of the incision. He is being evaluated for possible hyperthyroidism.

The patient's brother, who is five years older, had been operated for a right-sided neck mass two months previously in Detroit. This was also a carotid body tumor.

Comment

This rare tumor represents a non-chromaffin paraganglioma of the carotid body. The normal carotid body measures about 6 x 4 x 2 mm. and is located medially and behind the carotid bifurcation. The blood supply is chiefly from the external carotid and possibly a branch from the thyrocervical trunk. The carotid body has no endocrine function, although an occasional tumor of the body may secrete epinephrine.[1] De Costra in 1926 was the first to suggest that the carotid body might be a chemoreceptor. Chemoreceptor bodies are located at the carotid bifurcation, jugular bulb, aortic arch, and on the auricular branch of the vagus nerve, tympanic branch of the glossopharyngeal nerve, inferior ganglion of the vagus nerve and bifurcation of the aorta.[1] Tumors in these other sites are even more rarely seen.

The usual carotid body tumors are ovoid, firm, encapsulated, trabeculated and vascular. Histologically, carotid body tumors consist of large, eosinophilic cuboid or polyhedral* cells arranged in alveolar pattern, separated by thick, vascular trabecula[1] (Figure 3).

Familial Incidence

Chase noted the familial incidence of carotid body tumors as early as 1933.[2] Familial incidences of chemodectomas have since been reported by several writers.[3-5] *Bilateral* carotid body tumors are more likely to occur on a familial basis than in a sporadically occurring carotid body tumor.[4,6]

Carotid body tumors do have a malignant potential that has been reported

*See Test Your Word Score Page 53.

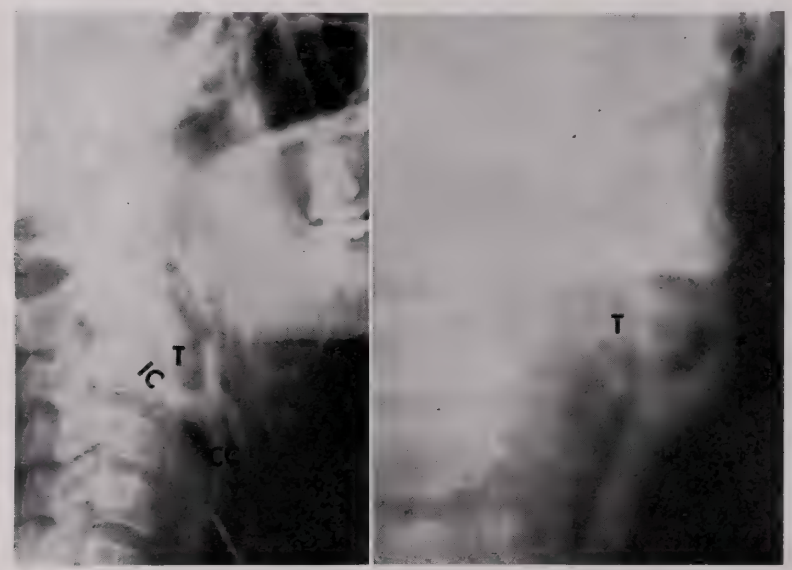

Fig. 1—(left) A lateral carotid angiogram showing the contrast material in the very vascular carotid body tumor. (right) An A-P angiogram showing the location of the carotid body tumor deep to the vessels. The internal carotid artery is displaced far laterally.

as 6.4% to 10%. Local and distant metastases have been reported.[6,7]

Differential Diagnosis

On a statistical basis, metastatic squamous cell carcinoma, brachial cleft cyst, metastatic cancer from the thyroid, lymphadenopathy, neurofibroma and metastasis from a distant site are all more likely diagnoses for a mass in the

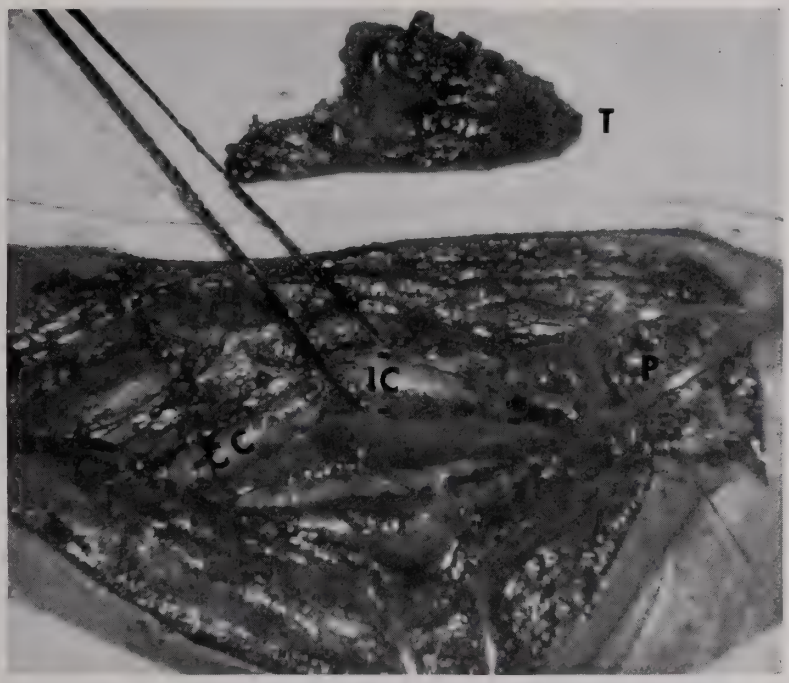

Fig. 2—A view at the time of operation. The markers show the narrowing of the internal carotid (IC) just under the parotid gland (P). The external carotid is behind the internal carotid. The tumor (T) is on the towel above.

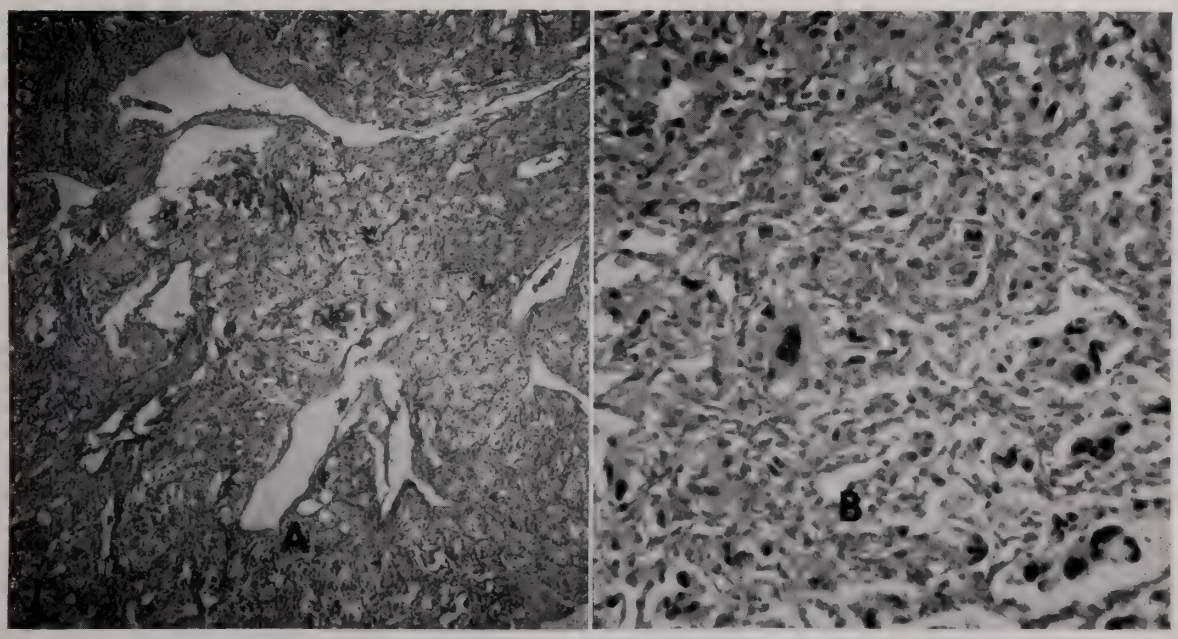

Fig. 3—(A-left) A low power view of the carotid body tumor showing the typical pattern and the numerous vascular spaces in the tumor. (B-right) A higher powered view of the tumor.

lateral neck.[8] The usual physical findings of a mass located just below the angle of the mandible that is non-tender and of long duration, that can be moved in the horizontal but not the vertical position, is characteristic but not diagnostic of a chemodectoma. Tumor involvement has been observed to induce a facial or accessory nerve weakness or, infrequently, a paralysis of the tongue or a Horner's syndrome. An occasional patient may have fainting with a carotid sinus syndrome.[9] Carotid body tumors extending deep to the carotid system can cause dysphagia.

Carotid angiography demonstrating the characteristic vascular tumor stain is the most reliable tool in the diagnosis of carotid body tumors. The angiogram may show an increase in the angle of the carotid bifurcation on the involved side and give helpful information on the cross-over of the cerebral circulation.

Risk of Operation

Any appreciation of the high-flow vascularity of these friable tumors would make it apparent that a casual incision biopsy would be a startling affair. In light of this vascularity and the position surrounding the carotid bifurcation, it is not surprising that Riegner's first attempt to excise a carotid body tumor in 1880 resulted in the patient's death. Mydl in 1886 resected a carotid body tumor. This patient survived—but with hemiplegia and aphasia. Albert in 1889 performed the first successful excision of a carotid body tumor without sacrificing the carotid vessels.

The fact that carotid body tumors do not regress but continue to grow, albeit slowly, has led surgeons to continue to attempt their removal. Radiation is of limited, if any, value.[6,7]

In earlier years when ligation of the carotid system was frequently performed, the operative mortality ranged from 20% to 58%—with more frequent brain damage. It is understandable then that up to a decade ago it was felt by many that attempts at removing carotid body tumors were not justified.[9] Two things have reduced surgical mortality to acceptable levels as low as 1.5% in Rushes' review:[10] wider familiarity with vascular surgical techniques, such as the internal vascular shunt, and diagnostic angiography.

As a final note to this case, it is difficult to know whether the narrowing of the internal carotid by the tumor contributed to the patient's neuropsychiatric problems. There has been no dramatic change to date.

"Man's best friend" in wintertime diarrheas

In winter "flu" and viral gastroenteritis, Donnagel (4 oz. size!) can bring aid and comfort to sufferers from both diarrhea and its discomforts because it contains kaolin and pectin plus belladonna alkaloids (as in Donnatal®). Donnagel treats the whole diarrhea problem. Available on your prescription or recommendation. A. H. Robins Company, Richmond, Va. 23220

A·H·ROBINS

CLEAR THE TRACT! ROBITUSSIN®

THERE'S A FORMULATION FOR EVERY COUGHING NEED

All the Robitussins contain glyceryl guaiacolate, the outstanding expectorant agent that greatly increases the output of lower respiratory tract fluid. Increased RTF volume exerts a demulcent effect on the tracheo-bronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise.

For coughs of colds and "flu"
ROBITUSSIN®
Each 5 cc. contains:
Glyceryl guaiacolate . . . . . 100 mg.
Alcohol, 3.5%

For unproductive allergic coughs
ROBITUSSIN® A-C
Each 5 cc. contains:

Neurological Conference

Stroke Convalescence*

This case represents one of the more perplexing problems that can be encountered in medical practice. The patient to be discussed has been partially disabled by a stroke in a way which is overtly inapparent to most people, and yet extremely obvious to him. Previously the patient had been a very good painter, but now he has lost the skill which had taken years of experience to develop. As the history and discussion are presented, the manifold ways in which this illness has affected both him and his family will become apparent. At this time, his future depends greatly on what we have to offer him.

History of Present Illness

Dr. Paul Martin:**

This 48-year-old painter first visited the University of Minnesota Medical Center on November 3, 1965. He was referred by his private physician for therapy to improve the function of his left arm. Prior to the present illness he had always enjoyed excellent health. On August 11, 1964, the patient had awakened and prepared to go to work; however, as he climbed into his truck, he noticed that he had difficulty raising his left arm to put the key into the ignition. Not thinking much of this at that time, he drove on to work. When he arrived at work, he found that he couldn't open the door of the truck to get out.

He was taken to his local hospital where he presented with a left hemiparesis involving primarily his left face and arm. An angiogram was performed which revealed a complete occlusion of the right internal carotid artery. Subsequently he was treated conservatively and much of the obvious paresis gradually cleared. The patient became increasingly aware of the fact that coordination in his left hand failed to improve. As a result, he found that he was unable to paint as he had before. After convalescing at home for about two weeks, he was seen by a neurosurgical consultant who recommended that an endarterectomy be performed. This was attempted, but the patency of the right internal carotid system was not re-established.

The patient returned to work for one month. Finding that he could not do the quality of work he had previously done, he became disgusted, quit his job and stayed home. Since then he has been extremely depressed and has resorted to drinking, which, according to him, made him feel "more normal." He had previously been quite successful as a painter, earning approximately $4.00 per hour as a foreman. Now his alcoholic intake is about one pint a day. Most of the time he sits at home doing nothing but brooding about his inadequacies. Prior to his present illness, he never had more than one to two shots in an evening.

While being questioned about his past history, the patient stated that he remembered two occasions during the previous three years when he had reached for an object with his left hand and missed. No other neurological symptoms were evident in the past history. He has had an elevated blood pressure occasionally in the past which was treated medically. During his initial hospitalization, a glucose tolerance test was suggestive of diabetes and he was placed on a diabetic diet.

*Neurological Conference held December 2, 1965. These conferences are an integral part of the comprehensive Clinic Program at the Universiiy of Minnesota Hospitals.

**Student Doctor, University of Minnesota Hospitals.

Physical Examination

On physical examination, the patient was a very well-appearing man with an outgoing, friendly personality. His blood pressure was 170/110 mm.Hg. bilaterally. Positive findings were confined to the lungs and nervous system. Regarding the former, a slight decrease in vital capacity was suggestive of early emphysematous changes. Neurological examination showed a mild persisting deficit in the left central seventh function and a slight incoordination of the left upper extremity. Dysmetria in the left arm and hand was apparent when he attempted volitional maneuvers. Questionable evidence of a peripheral neuropathy was found on sensory examination. Tests of reflex activity and motor strength showed no abnormalities. The visual fields were normal. A well healed surgical scar was present over the right anterior neck.

Routine laboratory data included a normal hemogram, urinalysis, and serology. The blood urea nitrogen was within normal limits. A glucose tolerance curve was again suggestive of mild diabetes, rising to 237 mg% at one hour and returning to 100 mg% at two hours. A chest x-ray was normal. Significantly, an electrocardiogram revealed evidence of a possible old posterior myocardial infarction, although this could not be documented historically.

Dr. Robert W. Soll:*

Surgical endarterectomy in the presence of a complete occlusion of the internal carotid artery must be done within the first six to eight hours after the occlusion occurs if it is to be successful. This is probably due to the formation of a thrombus distal to the occlusion extending through the carotid siphon in the base of the skull. The removal of such a thrombus is virtually impossible. On the other hand, if the thrombus is removed in the presence of a completed stroke, there is great danger of hemorrhage into the infarcted brain. An insufficiency resulting from a narrowing of the vascular lumen, on the other hand, is very amenable to surgery. Since this patient did have a complete occlusion of the right internal carotid artery and a prolonged interval had occurred between the onset of his symptoms and the attempted surgery, the likelihood for successful removal of the obstruction was virtually nonexistent.

Psychological Evaluation

Dr. John Brantner:**

Both the patient and his wife were interviewed. A thorough battery of brain function tests were administered to check for signs of brain damage. His I.Q. as measured by the full scale Wechsler Adult Intelligence test was 96, an average score which correlated well with his vocational achievement. On the other hand, the sub-test patterns were highly suggestive of brain damage. Both immediate and remote memory were reduced significantly. He was incapable of solving the Porteus Mazes, contrary to what would be expected on the basis of his intelligence. The most gross distortions appeared in his attempts to copy geometric figures since these involved hand-eye coordination. He was totally incapable of drawing a pencil line which would pass between two points 3/8 of an inch apart. Ballistic distortions appeared when he attempted to copy geometric figures; in other words, incoordination was quite gross and very evident. On the basis of this, it could be assumed that he would be completely incapable of painting in situations where one color met another. Although he was using his dominant hand, the left hand, his performance with that hand was quite similar to the performance usually seen with a nondominant hand.

Doctor Martin:

These findings correlate well with the patient's complaint of inability to "finish the wall." This is an expression used by painters for painting to the

*Neurologist, University of Minnesota Hospitals.
**Associate Professor, Clinical Psychology, University of Minnesota Hospitals.

line where the wall meets the ceiling.

Depression Following Stroke

Dr. Brantner:

The Minnesota Multiphasic Personality Inventory reflected a mild to moderate reactive depression in a passive somewhat dependent man. Many of these test results were ambiguous in view of his drinking, because similar findings such as incoordination can be obtained in persons following a period of intoxication. The patient's wife had mentioned that she disliked her husband's drinking although she understood why he did it and hoped someone would be able to do something about it. Other than housework, which he doesn't like, there is nothing for him to do. Apparently he has rarely been sober for a period of more than a few days during the past year. His drinking usually has been limited only to the point at which he staggers, never to coma.

The wife's multiphasic was entirely within normal limits. She appeared to be a mildly overcontrolled person and perhaps under very mild tension.

It would be interesting to maintain the patient in a controlled environment where he was not permitted any alcohol intake for a period of about 10 days, and then repeat the testing.

Physical Medicine Evaluation

Dr. Frank Meelhuysen:*

There was no decrease of strength in the patient's left extremities compared to his right. The range of motion in his left arm and leg was within normal limits except for diminished supination of the forearm. A persisting mild spasticity was still evident in the left biceps and forearm pronators. Mild proprioceptive loss was suggestive on the left side. These three factors produce most of the problems he has with coordination. It was felt, however, that these disturbances were not severe enough to require intensive therapy. Apparently the patient's private physician has suggested that the patient use his right hand more; however, I feel that increased use of his left hand also will gradually enable him to develop more skill, considering the mild degree of disability which seems to be present.

Location of Cerebral Lesion

Dr. Richard Magraw:**

Where is the probable location of the patient's lesion?

Dr. Soll:

The entire lesion may be diffuse, but most of the damage is probably located in the region of the genu and anterior portion of the posterior limb of the right internal capsule. The incoordination could be either on the basis of the spasticity or by virtue of the involvement of corticofugal fibers passing through this area and extending from the frontal lobe to the cerebellum via the pontine nuclei which bring the cerebellum under the control of psychosensory association areas of the cortex.

Doctor Martin:

The neurological findings were so minimal that he performed perfectly on finger to nose, but tended to error on reaching for a remote point in space. This mild disturbance as pointed out by Dr. Meelhuysen might be manifested

*Assistant Professor, Physical Medicine and Rehabilitation, University of Minnesota Hospitals.
**Director, Comprehensive Clinic Program, University of Minnesota Hospitals.

functionally by the fact that he tends to "streak" when painting.

Dr. Soll:

Such a loss, although minimal, can be as important to the patient as the loss of function of a finger would be to a pianist.

Dr. Magraw:

Why wasn't the patient attempting to improve himself if repeated use of his left hand would do this?

Dr. Meelhuysen:

I feel that the degree of cerebral damage directly correlates with the rehabilitation potential of a patient. Both physical as well as mental factors affect a patient's ability to recover from a disability, and certainly both are significantly involved in this case.

Social History

Mrs. Diane Crespin:*

I obtained the patient's permission to contact his former employer to learn more about his former job skills. The employer confirmed the fact that the patient had been a good worker and very dependable. He had been with them many years as a regular rather than seasonal worker. His salary was about $4.30 an hour or $170 a week as foreman of a painting crew. Following his convalescence, he failed to come to work on several occasions because of his drinking; however, prior to his present illness, drinking had never been a problem. The reasons given for his leaving the job was that the quality of his work was poor and it had to be done over again.

The patient now occupies his time by taking care of the housework and the dog. His current social security benefit is $124 a month. Since October, 1964, his wife has been working and she earns about $200 a month. Unfortunately they had accumulated no savings up to the time of his present illness.

Regarding the patient's reaction to his illness, he stated that he was having a difficult time adjusting to being unemployed. Also he found it hard to follow a diabetic diet since he was sitting home alone all day and eating. He would like to return to some type of work and had been trying to get employment as a taxi driver. He has shown some initiative in that he stated that he had been reading the want ads. Previously he had worked as a guitar player in restaurants and as a truck driver.

Other members of his family have all been in good health except one brother who died of a heart attack at age 48, a fact which has concerned the patient considerably. I feel that he would benefit by vocational rehabilitation. The best way to cope with his depression may be to find some way to return him to work. The former employer had thought the patient might like a job in a paint store, although this possibility has not been discussed with him.

Discussion

Dr. Meelhuysen:

Both the physical and psychological handicaps of the patient would tend to prevent his returning to his former job. Vocational counseling might be of benefit. This evaluation could be accomplished in the shop. I do not like the patient's idea of being a taxi driver, because of his reduced reaction time in case of an emergency as well as the responsibility involved in such

*Department of Social Service, University of Minnesota Hospitals.

a job. There are many other areas in which he might find a useful occupation. Painting might still represent the best type of work, not only on the basis of his past experience, but because it could be therapeutic by giving him a chance to use his left arm more. We should not expect the same quality of work that he has done in the past; for this reason, his supervisors should be informed of his present capability and the patient should be willing to take a lower position.

Dr. Magraw:

He has already tried painting and failed. It is possible that he has not yet recovered from the shock of this illness; consequently, simply returning to work may again leave him frustrated and more depressed. In addition to the patient's referral to rehabilitation, someone should work with him specifically in an attempt to stop his denial and face his loss. This would not have to be a formal psychiatric consultation; rather any one of his doctors could relate to him in this way.

Dr. Brantner:

This may be done during his contacts with skilled vocational counseling. The need for complete reorientation and vocational readjustment can be brought out. Factors which may help his reorientation are the occasional enthusiasm and eagerness which he has shown since his stroke. But he would have to be protected against failure which, if it occurred, would plunge him more deeply into depression.

Dr. Meelhuysen:

Special arrangements can be made with an employer which would enable the patient to work temporarily in a training capacity without pay. Similar arrangements have been made for many patients in the past. Prior to this the patient can spend one week, eight hours a day, in the pre-vocational shop to evaluate all of his present potential. Subsequently, admission to the hospital can be considered in order to obtain psychological testing in a more controlled environment.

Dr. Soll:

Short-term treatment of patients does not necessarily solve all of the problems an illness may present. This was true in this patient's case. A positive follow-through is a vital function for the physician in helping the patient return to a more normal life.

The plan for this patient was then summarized as follows:

1. Evaluation in the prevocational shop on an outpatient basis.
2. Appropriate vocational counseling and support with particular emphasis on protection against failure.
3. Reassurance by all therapists on the use of his left hand.
4. Psychological re-evaluation after the patient has been in a controlled environment one to two weeks in order to determine more definitely the degree of brain damage present.
5. Re-emphasizing to the patient the need for maintaining his diabetic diet.
6. Consideration of psychiatric consultation if the above plan fails to correct the patient's depression.

Phenaphen® with Codeine

the only leading compound analgesic that calms instead of caffeinates

Each capsule contains:

Phenobarbital (¼ gr.) ..... 16.2 mg.
(Warning: may be habit forming)
Aspirin (2½ gr.) .....162.0 mg.
Phenacetin (3 gr.) .....194.0 mg.
Hyoscyamine sulfate.....0.031 mg.
Codeine phosphate.....¼ gr. (No. 2),
½ gr. (No. 3), 1 gr. (No. 4)
(Warning: may be habit forming)

Contraindications: Hypersensitivity to any ingredient.

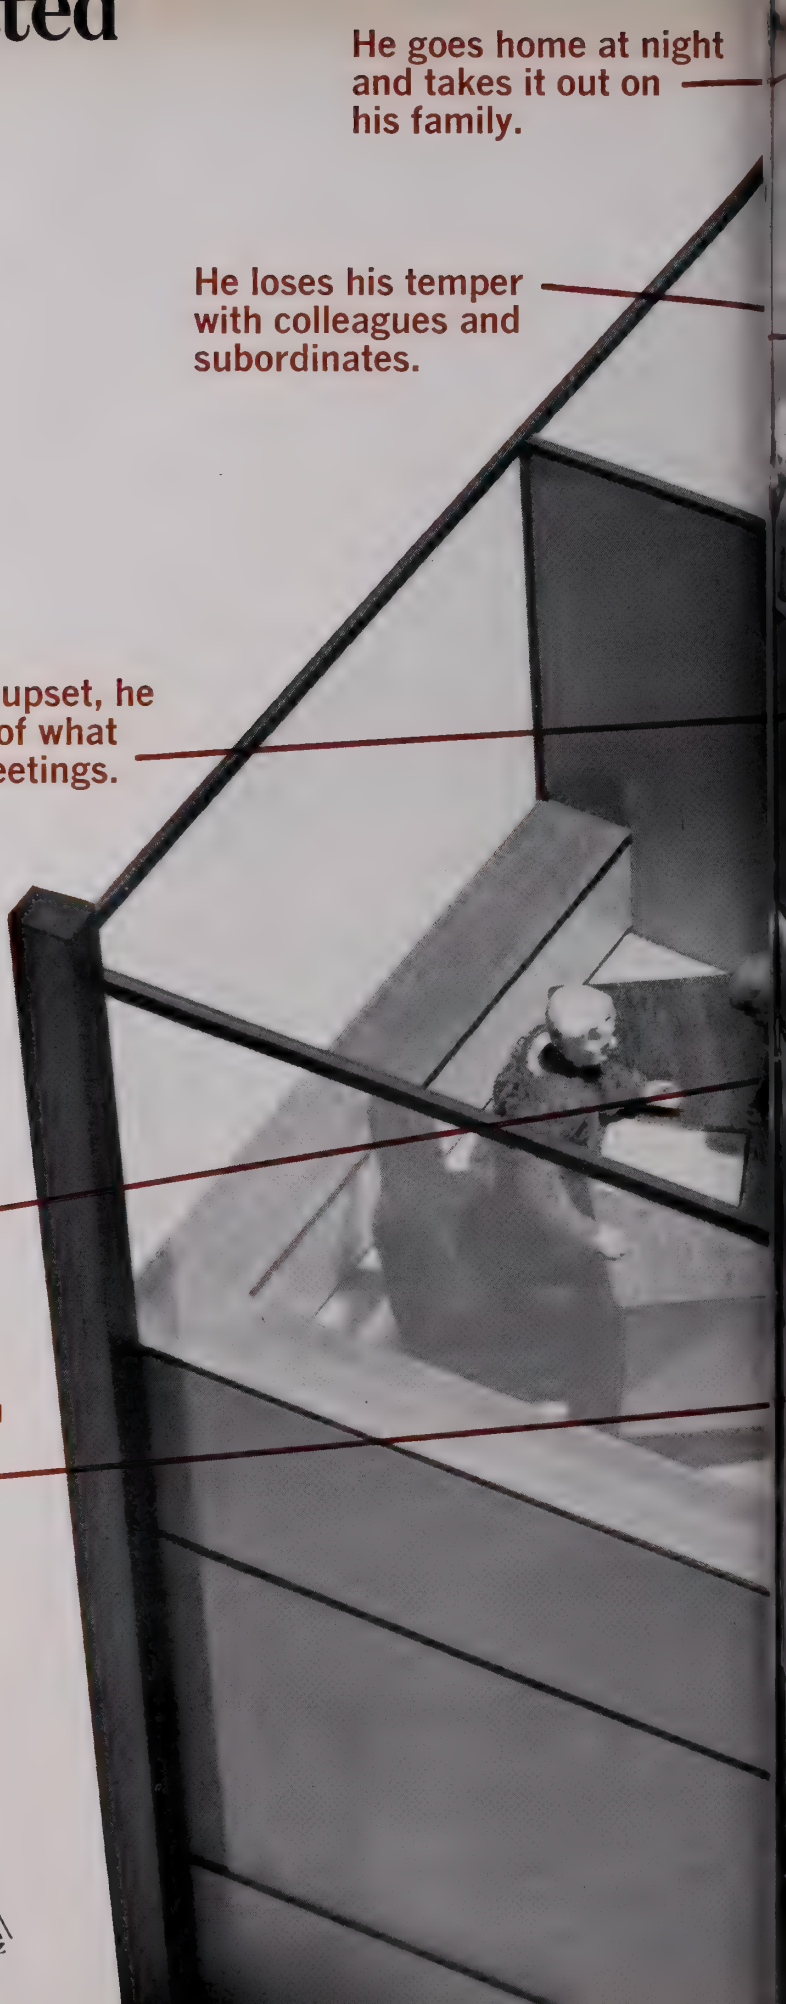
Precautions: As with all phenacetin-containing products, avoid excessive or prolonged use.

Side Effects: Side effects are uncommon—nausea, constipation, and drowsiness have been reported.

A-H-ROBINS

A. H. ROBINS CO., INC., Richmond, Va. 23220

When the agitated businessman goes to work...



He goes home at night and takes it out on his family.

He loses his temper with colleagues and subordinates.

Emotionally upset, he misses half of what is said at meetings.

He is always fearful about his standing with the boss.

He just can't seem to settle down to his work.

for moderate to severe anxiety

Mellaril®
(thioridazine)
25 mg. t.i.d.

SANDOZ

See following page for additional product information.

When the agitated businessman goes to work...

Anxiety that *seriously interferes* with the individual's performance at work, at home, or in the community may be regarded as *moderate to severe* in degree.

Mellaril often recommends itself to the treatment of moderate to severe anxiety because it

- helps control the most frequent symptoms: marked tension, agitation, apprehension, restlessness, hypermotility
- often alleviates anxiety-induced somatic complaints
- frequently helps strengthen emotional resources
- helps the patient maintain realistic contact with environment, closer harmony with family

Thus, when you consider the anxiety moderate to severe... consider Mellaril.

Contraindications: Severely depressed or comatose states from any cause, and in association with or following MAO inhibitors; severe hypertensive or hypotensive heart disease.

Precautions: Hypersensitivity reactions (e.g., leukopenia, agranulocytosis) and convulsive seizures are infrequent. Pigmentary retinopathy has been observed where doses in excess of those recommended were used for long periods of time. May potentiate central nervous system depressants, atropine, and phosphorus insecticides. Where complete mental alertness is required, administer the drug cautiously and increase dosage gradually. In addition, orthostatic hypotension (especially in female patients) has been observed. Epinephrine should be avoided in treatment of drug-induced hypotension.

Side Effects: Pseudoparkinsonism and other extrapyramidal disorders are infrequent; drowsiness, especially in high doses early in treatment, may occur; nocturnal confusion, dryness of the mouth, nasal stuffiness, headache, peripheral edema, lactation, galactorrhea, and inhibition of ejaculation are noted on occasion; photosensitivity and other allergic skin reactions may occur but are extremely rare.

Before prescribing, see package insert for full product information.

for moderate to severe anxiety

Mellaril®
(thioridazine)
25 mg. t.i.d.

SANDOZ

mudrane®

for

- EMPHYSEMA
- ASTHMA
- CHRONIC BRONCHITIS
- BRONCHIECTASIS

The fast-disintegrating uncoated tablet gives relief in 15 minutes

Each tablet contains:

Potassium Iodide	195 mg.
Aminophylline	130 mg.
Phenobarbital, Caution: May be habit forming...	21 mg.
Ephedrine HCl	16 mg.

FEDERAL LAW PROHIBITS
DISPENSING WITHOUT PRESCRIPTION

Precautions: Usual for aminophylline-ephedrine-phenobarbital. Iodides may cause nausea, long use may cause goiter. Discontinue if symptoms of iodism develop.

Iodide contraindications: tuberculosis, pregnancy.

DOSAGE

One tablet, with full glass of water, 3 or 4 times daily.

Dispensed in bottles of 100 and 1000 tablets.

MUDRANE GG—Formula, dosage and package identical to Mudrane—*except*—100 mg. glyceryl guaiacolate replaces the potassium iodide. The value of Mudrane cannot be enjoyed by a small group in which K.I. is contraindicated. Mudrane GG is prepared for this group.

MUDRANE GG ELIXIR—Four 5 cc teaspoonfuls is equivalent to one Mudrane GG tablet. Dosage adjusted to age and weight of child. Mudrane GG Elixir is for pediatric patients and those who think they cannot swallow tablets. Dispensed in pint and half gallon bottles.

Clinical Path Conference

Cyanosis, Seizures, and Hypernatremia in a Two-Week-Old Infant

Dr. W. Robert Anderson:*

A two-week-old infant was admitted to Hennepin County General Hospital for the second time because of "aspirating and a blue-gray color."

The child was born at Hennepin County General Hospital after a forty-week gestation complicated by slight first trimester spotting which lasted two weeks, and by rupture of the amniotic sac thirty-six hours prior to the delivery. The first stage of labor lasted five hours; the second stage was also rapid, being only five minutes in duration. No forceps were used. The third stage of labor lasted five minutes, and a circumvallate placenta with three cord vessels was delivered.

Postnatally the child did very well. He was noted to be minimally jaundiced on the third day of life. On the fourth day he was markedly jaundiced, and a bilirubin at this time was 24.5 mgm.%. An exchange transfusion was performed, which the child tolerated very well. There was no evidence of blood grouping incompatability and no sign of sepsis. The child remained vigorous throughout his hospital stay and was discharged on the tenth day, having received only the single exchange. On discharge he was given a complimentary pack of formula, containing six small bottles of ready-to-serve infant formula, and one can of concentrated infant formula, which required that it be diluted one to one with water before being given to the child. His discharge weight was 3390 grams.

During the first day after his discharge, he was fed the contents of the six small bottles, and then the contents of the can of concentrated formula without the necessary dilution. He was taking two ounces of this formula every two hours, and the mother noted that the child's diapers were consistently dry. He became increasingly fussy and irritable, and his respirations rapid. He then became cyanotic and was brought to the Emergency Room at Hennepin County General Hospital.

When first seen in the Emergency Room, he was acutely ill, cyanotic and in obvious shock. The respiratory rate was from 80 to 100 per minute, the heart rate was 60, the blood pressure was unobtainable, peripheral circulation was extremely poor, and the child was noted to be somewhat rigid. His temperature was 102° rectally and his weight 2,970 grams. The nares were clear, the mucous membranes of the mouth were dry and clear, the neck was supple and no masses were palpable. The lungs were clear to auscultation and the heart revealed no abnormalities. Peripheral pulses were unobtainable. Neurological examination revealed a severely distressed, agitated child whose movements were jerky and purposeless. No pathological reflexes were elicited.

---

*Associate Pathologist, Department of Pathology, Hennepin County General Hospital.

His admission laboratory results revealed him to have a hemoglobin of 14 Gm.%, a white blood count of 14,200, a sodium of 163, a chloride of 144 and a potassium of 3.3 meq/L. A saphenous cut-down was done. The child was flushed initially with .2% saline, following which the heart rate improved to 140 to 160 beats per minute, although the respirations remained rapid. The child voided, and then was begun on 1/3 normal saline at the rate of 3,000 cc. /m^2/day, which was calculated to replace his deficits and keep up with maintenance fluids over the next 36 to 48 hours. Six hours after admission the sodium was 159, chloride 144, and potassium 3.3 meq/L. As his color improved from cyanotic to pink, his tone went from slightly rigid to opisthotonic. He was also noted to be exhibiting jerky, tremulous movements of all extremities and a high-pitched, unusual, somewhat strangulated cry. He was then sedated with .66 cc. of paraldehyde rectally and was started on phenobarbital, 5 mg./kgm/day. Seventeen hours after admission the sodium was 173, potassium 6.5, chloride 143 and CO_2 9 meq/L. Calcium at this time was 10.8, BUN 108, and blood sugar 145 mg.%. Thirty hours after admission the child's urine output remained good; sodium was 145, potassium was 6.4, chloride 141, and CO_2 13 meq/L. He was continued on half normal saline. Thirty-nine hours after his admission the sodium was 153, potassium 5.7, chloride 132, CO_2 13, and BUN 84. The last serum electrolytes obtained just prior to cardio-respiratory arrest on the second day after admission were: sodium 147, potassium 3.5, chloride 125, and CO_2 11 meq/L. The calcium at this time was 9.5 mg.% and the BUN 46. Blood and spinal fluid cultures obtained on admission were sterile. Following the assumption of the opisthotonic position and the beginning of the tremors of the extremities which were interpreted as definite seizure activity, he remained in approximately the same status until approximately fifty hours after admission, when he suffered cardio-respiratory arrest.

Discussion

Paul G. Quie, M.D.:*

This two-week-old male infant was hospitalized for the second time at Hennepin County General Hospital for aspiration and cyanosis. He was born here after 40 weeks gestation. The mother was multiparous and the first trimester of pregnancy was complicated by spotting. This frequently occurs, but the significance is not known. However, it is worth while reporting, since this may be important in the evaluation of the spectrum of maternal viral infections that may occur: for example, rubella or cytomegalic virus disease. The amnionic sac ruptured 36 hours prior to delivery and this obviously may predispose to neonatal sepsis. In most series, it is recognized that there is a high incidence of sepsis in newborns when membranes have been ruptured for greater than 24 hours. However, it should also be emphasized that upwards of 70 to 80% of infants in such instances are perfectly normal. Consequently, each situation must be considered individually. The delivery was rapid but apparently not precipitous; however, the possibility of a traumatic delivery must be considered. There is no evidence that central nervous system damage was present at birth. The placenta and umbilical cord were normal and afforded no clue to the problem involved. The infant was normal at delivery.

He was minimally jaundiced on the third day and the bilirubin quite high, (over 24.5 mgm.%) on the fourth day. An exchange transfusion was performed which reduced the serum bilirubin. Only one exchange transfusion was necessary. There was no indication as to the cause of hyperbilirubinemia, although I would take exception to the protocol which states that there was no sign of sepsis. Jaundice itself is one of the best signs of sepsis, and recent studies published in the *Pediatric Clinics of North America* indicate that while respiratory distress is the leading manifestion of sepsis, it is closely followed by jaundice as a clinical manifestation of sepsis in the newborn. In such instances, there are probably cumulative factors which lead to hyperbilirubinemia, the most important probably being immaturity of liver function.

*Associate Professor, Department of Pediatrics, University of Minnesota Medical School.

Blood and spinal fluid cultures in this infant were negative, and this would seem to exclude bacteria as a cause of sepsis since negative blood cultures are infrequent in infantile sepsis.

The mother was given a complimentary pack of six cans of ready-to-serve formula and one pack of concentrated formula when the infant was discharged. The weight was normal on discharge. On the first day following discharge, he was given six small bottles of formula (24 ounces) which is not excessive and which in no way suggests diabetes insipidus. This was followed by the concentrated formula without the necessary dilution having been made. Prepared formulas are generally designed to simulate human milk and even when undiluted have protein, fat, carbohydrate, and mineral contents which are quite similar to cows milk (Table).

TABLE

Preparation	Protein	Fat	Carbohydrate	Minerals
Human	1.25%	3.5%	7.5%	.15%
Cow	3.5	3.5	4.7	.54
Similac	3.5	7.8	1.3	.75
Bakers	4.3	6.4	1.3	1.2

The infant apparently got only one bottle of the concentrated formula. The mother subsequently noted the diapers were consistently dry, and since this event took place in July, normally a hot month even in Minnesota, dehydration due to sweating from external heat could well have been an important contributing factor in this infant's dehydration.

During the second day at home he became irritable, developed respiratory distress, apparently aspirated, became cyanotic and was brought to the Emergency Room. Examination at that time revealed him to be cyanotic and in obvious shock with respirations of 100, a heart rate of 60, a rectal temperature of 102°, an unobtainable blood pressure, and poor peripheral circulation. The infant was moribund for all practical purposes, and neurologic examination revealed absent pathologic reflexes, jerky, purposeless movements, and increased tone. He had sustained a marked weight loss amounting to 12% of his body weight on discharge two days previously. Since his diapers had been consistently dry, it would seem that he had become dehydrated principally through sweating and increased respiration.

Several possibilities could be considered at this time which would be compatible with the history and clinical course. Birth injury cannot be excluded. It is also quite possible that this infant had a congenital infection even though the blood cultures were sterile. Organisms which do not grow on ordinary media are Toxoplasma or cytomegalic virus. The central nervous system signs this infant presented are compatible with infections with these organisms. One might also consider the possibility of a renal tubular abnormality with subsequent loss of fluids, inability to exchange ions, and concomitant retention of sodium and chloride. The electrolyte studies would be consistent with tubular acidosis or absence of antidiuretic hormones with associated diabetes insipidus.

On admission to the hospital, the infant was hydrated with initial improvement in heart rate and serum electrolytes, increased urinary flow and improved color. Signs of central nervous system damage persisted, however, characterized by irritability, a high pitched cry and tremulous movements of extremities.

It is quite possible that a combination of both increased electrolytes received in the concentrated formula together with excessive sweating culminated in

the dehydration and hypertonicity observed clinically. The irreversible downhill course in the hospital was probably on the basis of central nervous system damage and renal damage occurring during the shock episode. The etiology of shock, however, may have some other basis than dehydration. Neonatal sepsis is somewhat suggested by the history of premature ruptured membranes, subsequent unexplained hyperbilirubinemia, and antibiotic coverage following the exchange transfusion; but, with sterile cultures, such sepsis seems to be excluded. Cytomegalic virus infection or Toxoplasma infection is also a possibility. Serum levels of IgM in neonates may be helpful clues in the diagnosis of intrauterine fetal infection. Sera from newborns with IgM levels greater than 20% of the gamma globulin level are highly suggestive of previous intrauterine infection. It would seem that this procedure may be a helpful diagnostic measure in babies with unexplained jaundice.

Clinical Diagnoses

1. Probable central nervous system cytomegalic disease
2. Hypertonic dehydration
3. Secondary renal tubular acidosis

Pathology Discussion

Dr. Anderson:

Postmortem examination disclosed no evidence of sepsis, and, in particular, there were no changes suggestive of cytomegalic inclusion disease or toxoplasmosis. Findings, however, were those of a severe dehydration with its resultant complications. A definitive pathogenesis for this was not established, though probably a combination of excessive sweating together with intake of undiluted formula led to the state of dehydration and hypertonicity. At the time of hospitalization, central nervous system lesions were undoubtedly extensive and irreversible in spite of some initial improvement in the clinical course. The brain was the organ of most severe involvement, disclosing extensive engorgement and thrombosis of the major dural sinuses and intracerebral veins. There was extensive engorgement with virtually complete thrombosis of the superior sagittal sinus associated with focal hemorrhage into the adjacent falx cerebri. The major draining sinuses and

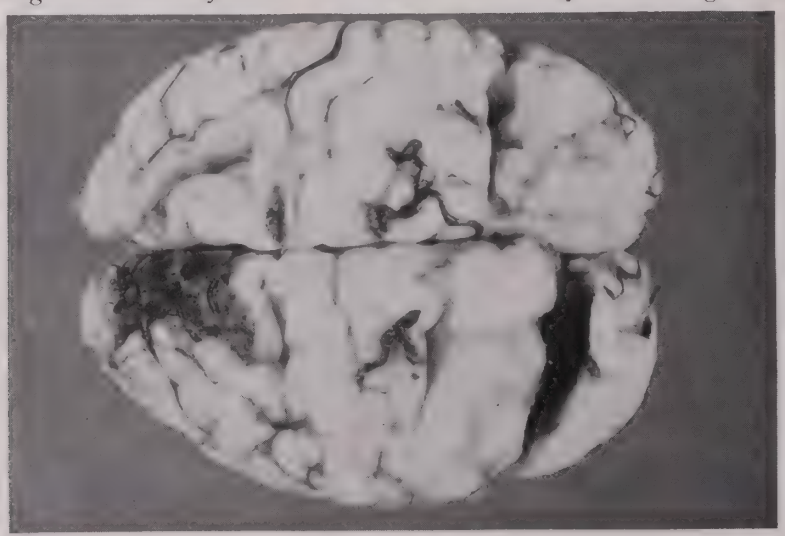

Fig. 1—Cerebral convexities showing distended thrombosed cortical veins and subarachnoid hemorrhage over the left superior frontal lobe.

cortical veins over the cerebral convexities also disclosed marked venous stasis and recent thrombosis. There was an extensive area of subarachnoid hemorrhage over the left superior frontal lobe that extended medially into the longitudinal cerebral fissure (Figure 1). Recent subarachnoid hemorrhages were also present bilaterally over the inferior cerebellar surfaces, and sectioning disclosed extensive hemorrhage throughout the ventricular system. The white matter of both cerebral hemispheres was the site of extensive necrosis of venous drainage areas characterized by widespread softening, cavitation, and hemorrhage into adjacent neural parenchyma (Figure 2). In these areas, venous engorgement and thrombosis were quite prominent. There was softening of the corpus collosum, and hemorrhagic softening of the internal capsule, caudate nuclei and thalamic nuclei bilaterally. The marked venous engorgement, stasis, distention, and early thrombosis of dural sinuses and intracerebral veins were confirmed in microscopic studies (Figure 3). Areas of venous infarction were characterized by dissolution and rarefaction of white matter, focal capillarization, and reactive astrocytosis.

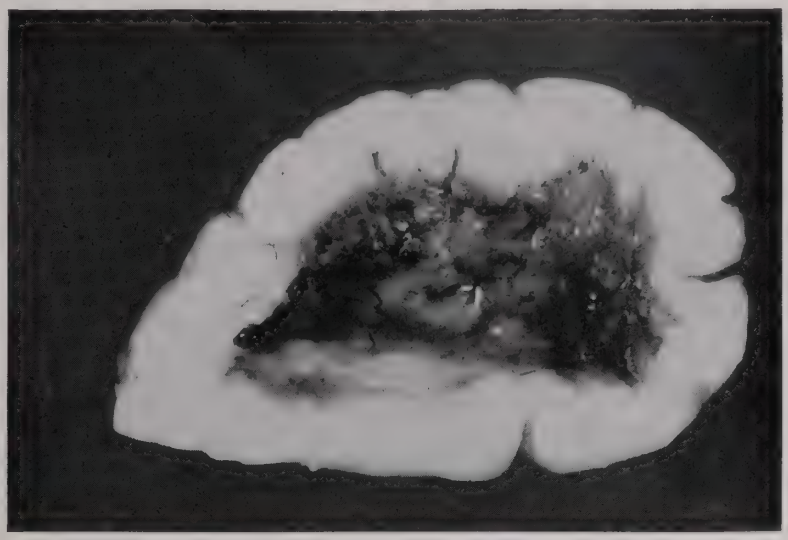

Fig. 2—Coronal section of cerebral hemisphere showing large cavitated area of necrosis involving white matter.

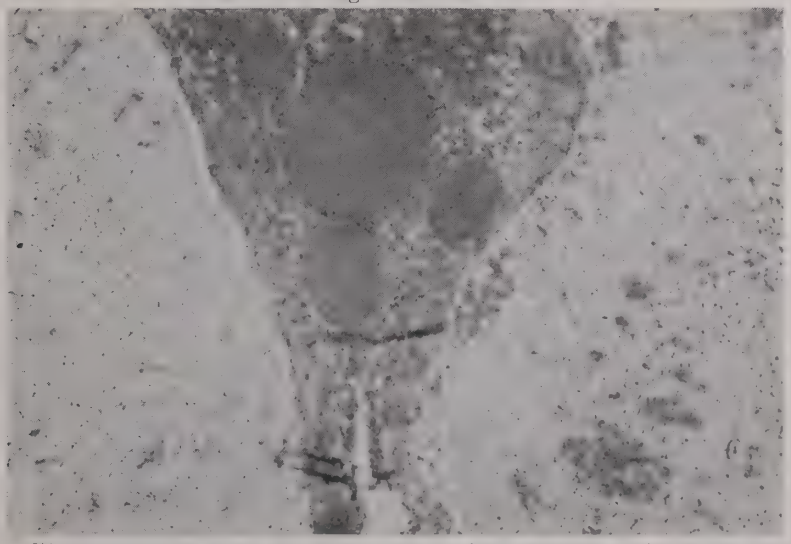

Fig. 3—Representative cerebral sulcus in which there is stasis and thrombosis of cortical veins, subarachnoid hemorrhage and focal cortical hemorrhages. Hematoxylin and eosin. x20.

Examination of other systems disclosed striking microscopic changes in the thymus, kidney and parotid gland. The thymus weighed 5 grams, whereas normal weight for this size infant would be 12 to 13 grams. Marked thymic involution was present, evidenced by a uniform depletion of cortical lymphocytes. These changes may be associated with sepsis, stress and dehydration, and probably the latter factors were both cumulative in this instance. The kidneys disclosed no abnormalities on gross examination. Microscopically, however, there was an extensive acute necrosis of proximal renal tubules that was attributed to both dehydration and shock with subsequent decreased renal blood flow (Figure 4). The parotid gland also showed effects of dehydration characterized by an acute sialadenitis with areas of interstitial inflammation and inflammatory destruction of acini. The lungs were not notably altered grossly, but microscopically did disclose pulmonary edema and an acute alveolitis, undoubtedly the precursor to a pneumonitis that would have ensued with longer survival.

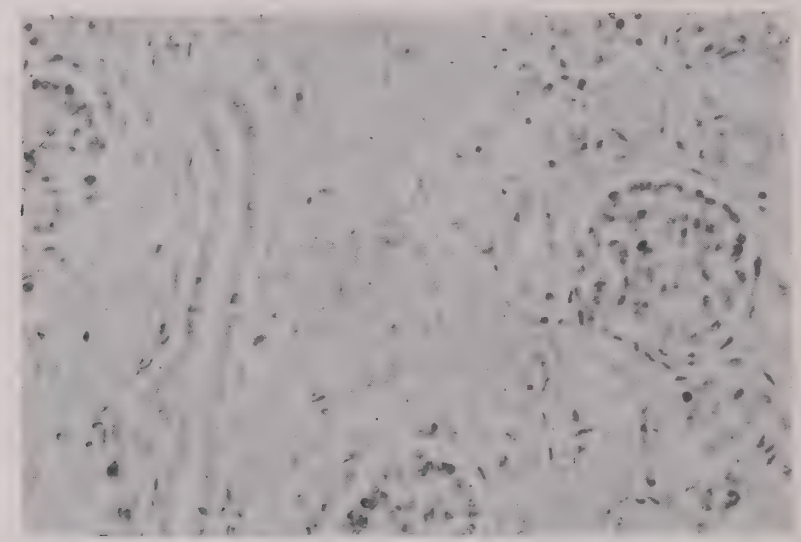

Fig. 4—Acute renal tubular necrosis in which proximal tubules are filled with desquamated granular necrotic lining epithelium. Hematoxylin and eosin. x50.

This case is illustrative of the not infrequent observation that subarachnoid and/or subdural hemorrhage may occur in states of dehydration with hypernatremia. Most observers attribute these changes to brain shrinkage and distortion. It is recognized that with hypertonicity, changes in brain size with shrinkage together with reduction in cerebrospinal volume and pressure do occur.[1-3] Furthermore, vessels in the brain receive some mechanical support from the surrounding neural parenchyma. With shrinkage this natural support is decreased; consequently these vessels may have increased liability to damage. It has been suggested that these factors are probably operative in hypertonic dehydration resulting in parenchymal shrinkage with secondary shearing and tearing of delicate bridging veins leading to subsequent subarachnoid and subdural hemorrhages.

A further point of interest is the frequent association of neurologic sequellae with states of dehydration and hypernatremia. In this particular instance, it is easy to relate neurologic symptoms with the widespread destructive lesions in the central nervous system. However, dehydration with hypernatremia has been frequently associated with neurologic symptoms in which there are no appreciable correlative anatomic findings.

Clinical and experimental studies suggest that in such instances there may be a biochemical derangement within the neuron due to cellular desiccation and to the formation of idiogenic osmols secondary to the breakdown of bound electrolytes.[1,2] In addition, hypocalcemia has also been observed in some instances of hypernatremic dehydration. Although its pathogenesis is not clear, nevertheless, this may further contribute to hyperirritability and other neurologic symptoms.[4]

Final Anatomic Diagnoses

1. Hypertonic dehydration with marked hypernatremia
2. Secondary thrombosis of dural sinuses and intracerebral veins with venous infarctions of cerebral hemispheres
3. Subarachnoid and intraventricular hemorrhages
4. Acute renal tubular necrosis
5. Acute sialadenitis
6. Involution of thymus

Darwin on Communal Society*

"The perfect equality among the individuals composing the Fuegian tribes,** must for a long time retard their civilization. As we see those animals, whose instinct compels them to live in society and obey a chief, are most capable of improvement, so it is with the races of mankind. Whether we look at it as a cause or consequence, the more civilized always have the most artificial governments. For instance, the inhabitants of Otaheite,† who, when first discovered, were governed by hereditary kings, had arrived at a far higher grade than another branch of the same people, the New Zealanders—who, although benefited by being compelled to turn their attention to agriculture, were republicans in the most absolute sense. In Tierra del Fuego, until some chief shall arise with power sufficient to secure any acquired advantage, such as the domesticated animals, it seems scarcely possible that the political state of the country can be improved. At present, even a piece of cloth given to one is torn to shreds and distributed; and no one individual becomes richer than another. On the other hand, it is difficult to understand how a chief can arise till there is property of some sort by which he might manifest his superiority and increase his power."—Stewart Lane Arey, M.D.

It's the Law

Suit Against Hospital for Breach of Express Warranty in Furnishing Contaminated Blood Dismissed*

A suit for damages against a hospital by the husband of a patient who died from serum hepatitis after she received a blood transfusion in the course of prenatal care was properly dismissed by trial court. The husband claimed that blood, administered by a hospital, carried an express and implied warranty of purity. After receiving the blood the patient developed serum hepatitis and expired.

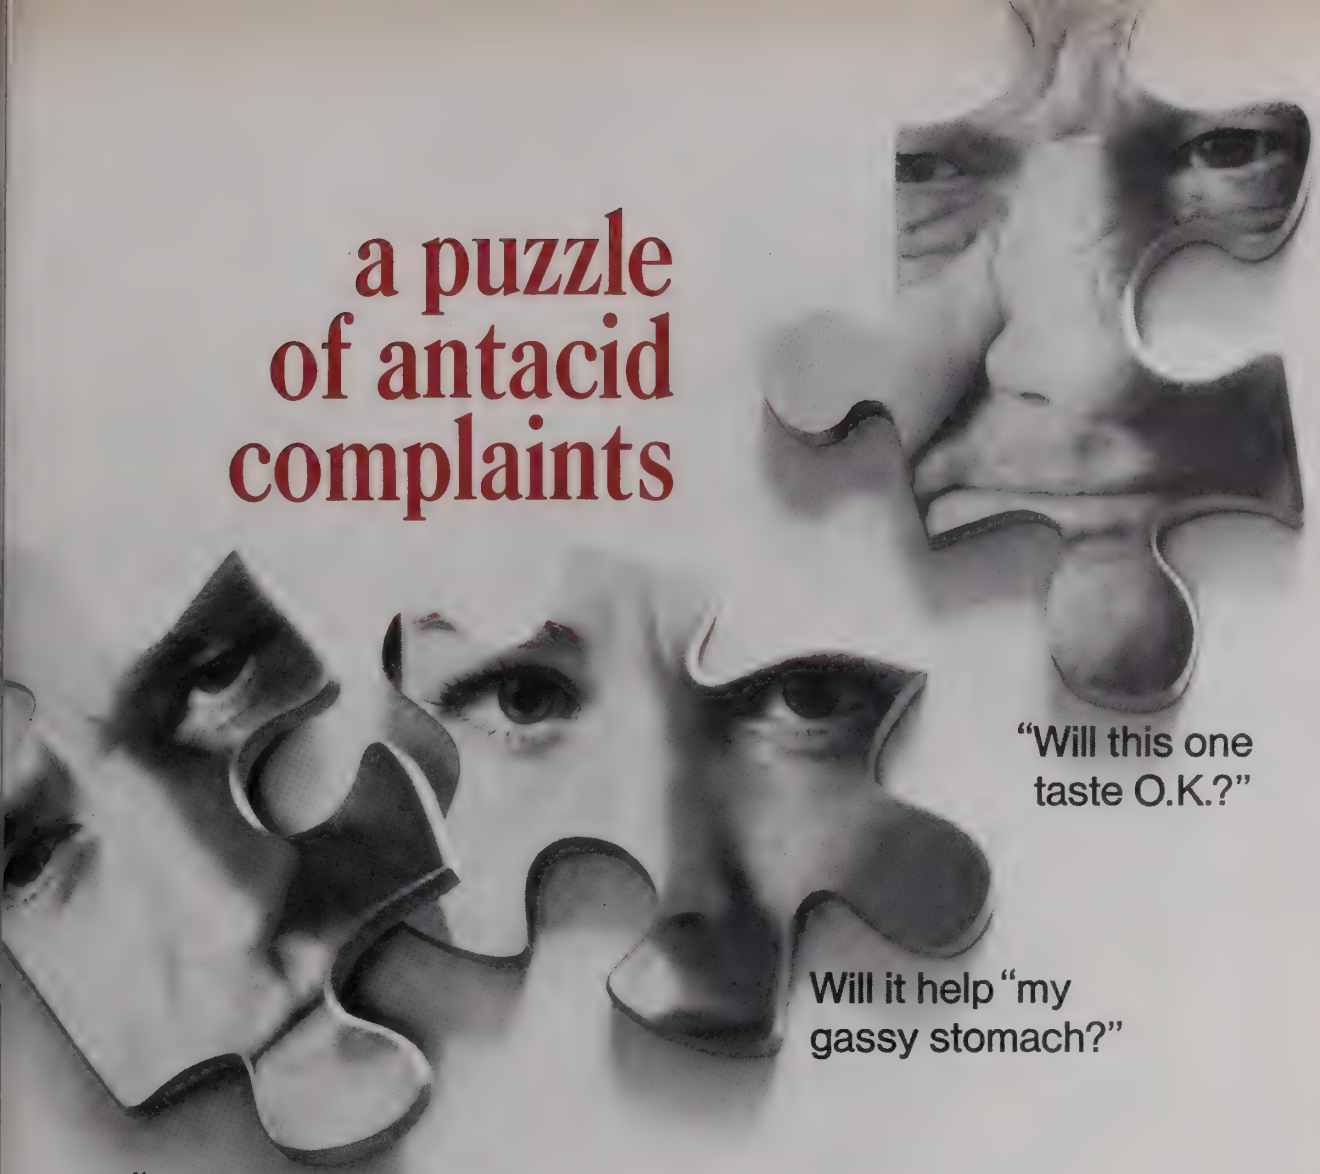
The rule, developed in prior cases against hospitals for damages for breach of implied warranty for having furnished contaminated blood, was applicable. A hospital's furnishing of blood for transfusion is termed a "service," not a "sale." Since there is no "sale," there is no cause of action for breach of warranty.

*Case Reference—Payton v. Brooklyn Hospital, 224 N. E. 2d 891 (N. Y., January 19, 1967) "The Citation" Vol. 15, No. 6, June 30, 1967.

All You Had to do Was to Take Stock of Yourself

I sat down with paper and pencil to plot my future . . . I tried to go back over my life and recall one useful thing I had done well and enjoyed doing, to dislodge from the debris of ineptitude a single small splinter of natural ability with which to prick my way into a career that would mean stability, security, and self-respect.

In turning back the pages I came eventually to Mr. Stilts. Mr. Stilts was a snow-white stork of entrancing ungainliness which had been given to me for my tenth birthday. Until the Revolution separated us Mr. Stilts and I were devoted companions during the summer vacations which I spent on our estate near Minsk. We both found the same delight in wading knee-deep in the marshy edges of a near-by stream and splashing muddy water up to our necks. He had a great flair for sticking his long neck and legs into the places it was unhealthy for a stork to be. My mother made quite a moral of it when as the result of straying he was carried home one day with a broken leg. I was in no mood for morals. Mr. Stilts was in trouble. For all I knew Mr. Stilts was dying.



I gathered Mr. Stilts up in my arms and ran with him to a shed some distance from the barn. There I laid him on a box and examined the leg to find the two ragged ends of bone. With infinite care I pressed them together and bound the leg rigid with splints cut from an old board and bandages extracted from my undershirt. In two weeks Mr. Stilts was as good as new.

It had been years since I had thought of my youthful career as an animal doctor, but in remembering it at long last I could still recapture a little of the thrill of success when Mr. Stilts came out of his bandages whole and without a limp. That was something I had done well and enjoyed doing. This great American game of planning one's future was beginning to make sense. There was nothing to it once you found the formula. All you had to do was to take stock of yourself, find the thing you would like doing, and then let nothing stand in the way of doing it.*

a puzzle of antacid complaints

Mylanta®

aluminum and magnesium hydroxide *plus* simethicone

a solution to peptic ulcer distress

Effective neutralization—
with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

Concomitant relief of G.I. gas distress—
with the proven[1] defoaming action of simethicone.

Prolonged acceptance confirmed—
in 87.5% of 104 patients after a total of 20,459 documented days of therapy.[2]

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

new evidence for TAO® (triacetyl-oleandomycin)

a macrolide antibiotic for the frequently seen respiratory infection in the office and for a problem pathogen* in the hospital.

*Staphylococcus aureus

study I[1]

Results of a 1967 **in vitro—in vivo** correlation study involving 116 patients with Gram-positive coccal infections in five institutions. All patients were given TAO prior to determining the susceptibility of the offending organism.

97.0%
of the organisms were susceptible to oleandomycin*

98.0%
of the patients responded favorably to TAO® (triacetyloleandomycin)

*In some cases more than one pathogenic organism was isolated from the patient.

study II[2]

Effect of oral therapy with TAO, erythromycin, and cloxacillin on the survival time of Rhesus monkeys after intravenous inoculations of lethal doses of staphylococci, phage type 80/81. (8 monkeys in each group)

conclusion:

*Under the conditions of this study and the doses employed, it was found that

TAO® (triacetyl-oleandomycin)

was far superior to erythromycin, as was cloxacillin, a bactericidal agent, and of particular interest, "...bacteriostatic triacetyloleandomycin was as effective or perhaps superior to cloxacillin in preventing lethal (staphylococcal, phage type 80/81) infection."

*It should be pointed out that results obtained in an experimental study of this nature may not necessarily be directly extrapolated to the clinical situation as it pertains to man.

TAO Rx Information

INDICATIONS: Include streptococci, staphylococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents. **CONTRAINDICATIONS AND PRECAUTIONS:** Not recommended for prophylaxis or in the treatment of infectious processes which may require more than ten days continuous therapy. In view of the possible hepatoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents should be used. If clinical judgement dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. When treating gonorrhea in which lesions of primary or secondary syphilis are suspected, proper diagnostic procedures, including darkfield examinations, should be followed. In other cases in which concomitant syphilis is suspected, monthly serological tests should be made for at least four months. Contraindicated in pre-existing liver disease or dysfunction, and in individuals hypersensitive to the drug. Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions. When used in streptococcal infections, therapy should be continued for ten days to prevent the development of rheumatic fever or glomerulonephritis. The use of antibiotics may occasionally permit overgrowth of nonsusceptible organisms. A resistant infection or superinfection requires re-evaluation of the patient's therapy. In the event such occurs with this drug the medication should be discontinued, and specific antibacterial and supportive therapy instituted.

For your impatient cold patients

Two sprays from NTZ Nasal Spray—and nasal congestion, rhinorrhea, sneezing are reduced for *immediate* comfort for patients with colds.

NTZ is more than a simple vasoconstrictor. It contains:

Neo-Synephrine® **(brand of phenylephrine) HCl 0.5 per cent,** the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction on contact.

Thenfadil® **(brand of thenyldiamine) HCl 0.1 per cent,** topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® **(brand of benzalkonium, as chloride, refined) 1:5000,** antiseptic preservative and wetting agent to promote penetration and spread of the formula.

NTZ is well tolerated. Used in a cold it may help prevent sinusitis by opening sinus ostia and permitting drainage. It may also be used in sinusitis to help establish drainage.

The spray is best used twice, the second a few minutes after the first, repeated every three or four hours as needed. NTZ is for temporary relief of nasal symptoms, and overdosage should be avoided.

Supplied: NTZ Nasal Spray, plastic squeeze bottles of 20 ml.; NTZ Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

Use of Lithium Carbonate in Private Psychiatric Practice

MOST DOCTORS well remember a disheveled, bizarrely-attired patient, bleary-eyed from lack of sleep, unable to sit still because of a frenzy of activity, and speaking in a flurry of words about grandiose personal plans. Treatment for this manic patient usually includes tranquilizers and/or electro-convulsive therapy. Tranquilizers often result in a rigid, lethargic patient who stays in the hospital for several months until the natural course of the attack is complete. Electro-convulsive therapy may result in a quicker recovery but is complicated by partial memory loss. These treatments are particularly detrimental to patients who need factual information to adequately perform their job and cannot afford to miss much work.

Early Use of Lithium Therapy

Within the past decade lithium salts have been popularized as a new therapy for this manic state. Cade's 1949 discovery that the lithium ion can erase endogenous excitement[1] found wide acceptance outside of the United States. Eighteen studies from 1954 to 1960 report 80-90% improvement in 370 manic patients treated with lithium.[2] Reports indicate that maintenance of lithium blood levels act as prophylaxis against recurring manic or depressive attacks.[3] Only recently have American psychiatrists tried the drug and recorded their favorable results.[2,4]

Establishment of Lithium Treatment in Minnesota

In 1955 Northwestern Hospital in Minneapolis began performing serum lithium determinations and dispensing 300-mgm. lithium carbonate capsules. These efforts were initiated by the author to provide lithium treatment for manic patients in the Twin Cities area. At the current time lithium carbonate is under thorough investigation, and physicians using it are requested to claim investigational exemption authorized by the Food and Drug Administration. The lack of physician familiarity with lithium carbonate in the treatment of manic disorders prompted the preparation of this paper, based on the author's experience with 15 patients.

Initial Treatment Procedure

The first step should be confirmation of the diagnosis of the manic state. The individual may suffer from organic illness or drug abuse. After the manic diagnosis is made, the patient should be hospitalized before the doctor begins treatment with lithium carbonate. (In three patients who were treated on an outpatient basis lithium therapy failed because of inadequate control of the patients and the medications.) Outpatient treatment can prove dangerous, as the psychotic patient may misinterpret drug instructions. There is no substitute for hospitalization. Once hospitalized, the patient is evaluated with a thorough examination, particularly as to cardiac and urinary status. Either coronary or kidney damage contraindicate use of the drug. Women of childbearing age are excluded to avoid possible fetal damage.

Control of Lithium Dosage

The selected patient is begun on 300 mg.

lithium carbonate capsules, t.i.d., given with meals to decrease any initial nausea and gastric distress. (One patient declined lithium because of this distress.) Most patients tolerate a rapid build-up of medication to the point of two capsules, t.i.d., or 1800 mg. of lithium carbonate per day. They are continued on this level until either their serum lithium level approaches 1.8 meq./liter or the manic attack "breaks." The latter phenomenon is comparable to a fever crisis before the antibiotic period and occurs usually within a week. To adequately control the patient until the serum lithium increases, sedative drugs are given. Thorazine or Taractan may be necessary up to 800 mg. per day during the first week, but then can be decreased rather rapidly. Patients are notified that lithium may cause gastric distress, fine tremors of the hands, and some sleepiness. They are advised to salt their food regularly to help prevent toxic build-up of the lithium salts.

Monitoring Lithium Levels

Serum lithium tests are started about four days after beginning the drug and should be performed at least twice a week. If the patient becomes clinically toxic with excessive somnolence, ataxia and slurred speech, serum lithium levels should be done more frequently. Levels are therapeutic between 1.5 and 1.8 meq./liter. Levels lower than this will probably not "break" the manic attack and levels higher approach a dangerous toxic range. Clinical impressions do not always correlate with the lithium level; therefore laboratory tests are essential. If toxic symptoms appear and the lithium level approaches 1.8 meq./liter, discontinuing the lithium for one or two days will bring the level under control. When the manic attack "breaks" the patient quickly becomes sensitive to the lithium. The dosage has to be decreased rapidly to one capsule, t.i.d. or q.i.d.; otherwise there is toxic danger to the patient. As the patient returns to a normal affective level a maintenance amount of lithium should be given. About three capsules per day will maintain him at a baseline of about 1 meq./liter, will provide safety from toxicity, and is at the level suggested to prevent recurrence of manic episodes.

Aftercare Treatment of Patient and Family

Much cooperation from the patient and his family is necessary for long-range success.[5] Individuals who resist medication and will not cooperate on drug programs should be handled by other treatment. Before a patient is released from the hospital a conference should be held with him and his family. At this time the danger signs of impending mania are discussed. Each individual has mannerisms which are clues to an impending manic attack. Thorough discussion of these clues familiarizes the family with these danger signs. The family and the patient will be instructed to call the doctor immediately if any of the mannerisms appear. The patient should be informed that a doctor's request at that time to go into a hospital and/or increase the lithium should be followed, even though the patient may not feel it is necessary. Also at the conference signs of lithium toxicity should be discussed with the family so that they will call the doctor in case of dangerous build-up of lithium salts.

Results of Treatment

Of the 15 study patients treated with lithium carbonate, 14 were manic-depressive patients, manic type. The other was a manic-depressive psychotic, depressed type, who suffered a recurring depression despite maintenance therapy with lithium carbonate. Three other treatment failures were study patients treated as outpatients. Poor medication control appears significant in their lack of improvement. All 11 patients hospitalized and adequately treated with lithium carbonate had their manic attack "break" within two weeks of beginning controlled treatment. Unfortunately two patients have had recurrent attacks despite maintenance lithium carbonate therapy. The second attack was adequately treated by hospitalization and increase of dosage. In three study individuals who became hypomanic on maintenance therapy, an increase of dosage aborted the attack and prevented hospitalization. Ten of the study patients continue on maintenance therapy. No serious side-effects have appeared and no discontinuation of medication has been necessary.

Summary

Lithium therapy in manic attacks is a new

mode of treatment which was successful in terminating manic attacks in all 11 patients hospitalized and adequately treated with lithium carbonate. It appears to offer a new range in therapy without the oversedation of tranquilizers and the forgetfulness of electroshock therapy, and without a prolonged hospitalization for the patient. Careful adherence to hospitalization, dosage schedule, and serum lithium tests is necessary for successful therapy. Otherwise dangerous toxic side-effects may jeopardize the patient's health. Selective use of lithium carbonate in private psychiatric practice appears beneficial and safe in treating manic patients.

Mr. President—Your Health*

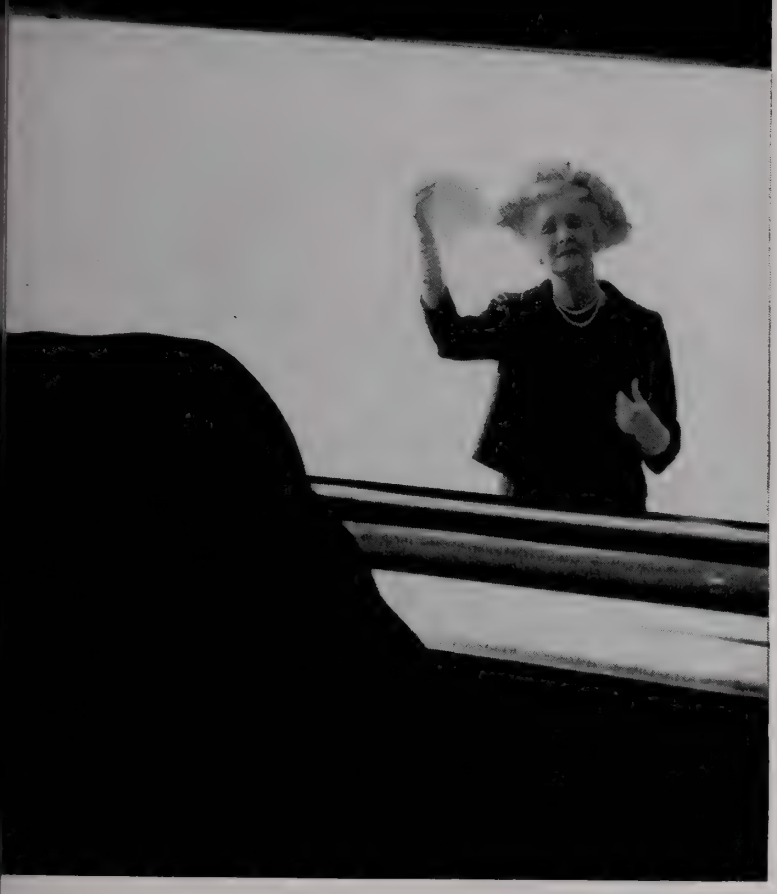
John Quincy Adams (1767-1848)

Deliberately and unremittingly imposing upon himself a regimen of walking, swimming, horseback riding and moderation, our sixth President, John Quincy Adams, kept himself physically fit right up into middle age. Despite good health, however, he was plagued with misgivings about his constitutional stamina. He complained of insomnia: "I get but five hours a night of disturbed sleep—full of tossings." Also he was unduly discouraged by bouts of laryngitis which impaired his public-speaking voice.

While Adams was a congressman, his health finally registered the full impact of over-strenuous and conscientious public service; one day after leaving the House he fell precipitately to the floor, gashing his forehead and dislocating a shoulder, the agonizing reduction of which took over an hour in time and stoic endurance on Adams' part. Whether he tripped on a mat or was the victim of a slight stroke was never determined; but thereafter his vision began to weaken and his hand to shake, symptoms he regarded as premonitory of final dissolution.

After a genuine stroke from which he only partially recovered, he was wont to reply with serene detachment to all queries about his health: "John Quincy Adams himself is quite well, thank you. But the house in which he has been living is now dilapidated. It totters on its foundations. Time and the seasons have nearly destroyed it. The walls are shattered, and the building trembles in every wind. Before long, John Quincy Adams will have to move out. But he himself is quite well."

One day at the age of eighty he collapsed in the House. Physicians tried to restore him by cupping, bleeding, poulticing, leeching, and rubbing—all to no avail. Under the dark shadow of death he recovered consciousness only sporadically, and his final words were: "This is the last of earth! I am content."



*With acknowledgements to Karl C. Wold, M.D.: Mr. President—How Is Your Health?

Perhaps we would never do all we do without the hope of doing more than we can.—Bernard de Fontenelle

Indications: Tofrānil is recommended for the treatment of depressive states of diverse psychopathology.
Contraindications: The concomitant use of Tofrānil and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 7 days after M.A.O.I. therapy has been discontinued should be allowed before Tofrānil may be substituted. Initial Tofrānil dosage should be low, increases should be gradual, and the patient's progress should be carefully observed.
Warning: Clinical reports have suggested that there may be a risk of teratogenesis associated with the use of this compound during the first trimester of pregnancy. Unless, in the opinion of the prescribing physician, the potential benefits outweigh the possible risks, Tofrānil should not be used during the first trimester of pregnancy.
Cardiovascular complications, including myocardial infarction and arrhythmias, have occasionally occurred in susceptible individuals. Patients with cardiovascular disease should be given the drug only under careful observation and in low dosage.
Precautions: Since suicide is always a possibility in severely depressed patients and one which may persist until significant remission occurs, such patients should be carefully supervised during early treatment with Tofrānil. Some severely depressed patients may also require hospitalization and/or concomitant electroconvulsive therapy.
Because of its anticholinergic effect, caution should be observed in prescribing Tofrānil for patients with increased intraocular pressure.
In rare instances, transient cardiac arrhythmias have occurred in hyperthyroid patients and in patients receiving thyroid medication when Tofrānil was added to the regimen.
Imipramine may block the pharmacologic activity of guanethidine and other related adrenergic neuron-blocking agents.
The drug is not recommended at the present time in patients under 12 years of age.
Adverse Reactions: Dryness of the mouth, tachycardia, constipation, disturbances of accommodation, sweating, dizziness, weight gain, urinary frequency or retention, nausea and vomiting, peripheral neuritis, mild parkinson-like syndrome, tremors, rare cases of falling in elderly patients, confusional states (with such symptoms as hallucinations and disorientation), activation of psychosis in schizophrenics and agitation (includ-

When a milestone in life is marred by depression...

Often in the mind of the lonely, widowed, depression-prone individual, she's not gaining a daughter...she's losing a son. The occasion may be marred by such symptoms of depression as feelings of sadness, incapacity, helplessness and hopelessness.

In about 3 out of 4 cases, Tofrānil relieves symptoms of primary depression.

As maintenance therapy in primary depressive illness, it helps prevent relapse.

Although toxic reactions severe enough to require discontinuation of Tofrānil are uncommon, in patients with cardiovascular disease, thyroid disorders, increased intraocular pressure, or in those receiving anticholinergics (including antiparkinsonism agents), the special precautions listed in the Prescribing Information should be carefully observed. The use of Tofrānil in patients receiving M.A.O.I.'s is contraindicated.

Tofrānil® imipramine hydrochloride Geigy

ing hypomanic and manic episodes) which may require dosage reduction and/or addition of a tranquilizer or temporary discontinuation of the drug, epileptiform seizures, orthostatic hypotension and substantial blood pressure fall in hypertensive patients, purpura, transient jaundice, bone marrow depression including agranulocytosis, sensitization and skin rash including photosensitization, eosinophilia, and mild withdrawal symptoms on sudden discontinuation after prolonged treatment with high doses. Occasional hormonal effects (impotence, decreased libido, and estrogenic effects) may be observed. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those using anticholinergic agents (including antiparkinsonism drugs).
Outpatient Adult Dosage: Initially, 75 mg. daily, increased, if necessary, to 150 or 200 mg. Maintenance dosage may be lower, 50 to 150 mg. daily, if possible.
Geriatric and Adolescent Dosage: Initially, 30 or 40 mg. daily, which may be increased according to response and tolerance. It is usually unnecessary to exceed 100 mg. daily.
A lag in therapeutic response, lasting from a few days to a few weeks, should be expected. When dosage recommendations are already being followed, increasing the dosage does not normally shorten this latency period and may increase the incidence of adverse reactions.
Availability: Tofrānil: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Dermatology

Melasma (Chloasma)

PIGMENTATION WHEN irregular in nature or unequal in intensity is cosmetically objectionable to many patients, men as well as women. The term melasma is used in a restricted sense to describe hyperpigmentation occurring in pregnancy, in menopause, with ovarian disorders, and with the use of oral contraceptives. It has also been reported in patients receiving hydantoin preparations. In pregnancy the areas most frequently involved are the face, areolae of the nipples, external genitals and the linea alba. Melasma varies in intensity and usually decreases after pregnancy. Melanin is responsible for this pigmentation and in pregnancy is probably due to the increased pituitary melanocyte-stimulating hormone circulating in the body. The mechanisms whereby melanin is increased in the other conditions are not clearly understood. With respect to hydantoin preparations it has been shown experimentally that in fish, at least, this drug has a direct effect consisting of dispersion of melanin and subsequent stimulation of melanin formation. Estrogen and progesterone are strong melanogenic stimulants which probably account for the action of the oral contraceptives in producing melasma-like changes. Of interest is the subjective darkening of the periocular skin and occasionally other areas noted in some women with relation to the menstrual

Figure

cycle. In young women a condition referred to as melasma peribuccale virginum is considered to be related to the tendency to menstrual pigmentation.

It should be noted that chlorpromazine therapy produces darkening due to the deposition of a melanin-like pigment in the dermis. This differs from melasma in that the color is more bluish and the eyes are involved, which is not the case with melasma.

Once the diagnosis of melasma is determined and the etiology clarified, treatment may be instituted, though it is not always successful. Treatment may be divided into three phases. First, removal of the exciting cause if possible. In this area the physician is limited, for in many instances, little can be done, except for the drugs mentioned. Second, an attempt to inhibit the tyrosine-tyrosinase reaction by the use of hydroquinone, which is available for topical application. But this drug must be used with caution, for it can be a potent topical sensitizer. Third, protection from sun exposure which further darkens areas of melasma. This may be achieved by the use of one of the several so-called "sun-screens." The patient should also be advised against such practices as sun-bathing.

In conclusion, it should be mentioned that other causes may be responsible for increased pigmentation, such as post-inflammatory melanosis; melanoderma secondary to malaria, pellagra, diabetes, Addison's disease, metastatic melanoma, to mention a few. All of these should be considered when one sees a patient with increased pigmentation.

The Progress Notes of Hippocrates

A man, in a heated state, took supper, and drank more than enough; he vomited the whole during the night; acute fever, pain of the right hyponchondrium, a softish inflammation from the inner part; passed an uncomfortable night; urine at the commencement thick, red, but when allowed to stand, had no sediment, tongue dry, and not very thirsty. On the fourth, acute fever, pains all over. On the fifth, urine smooth, oily, and copious; acute fever. On the sixth, in the evening, very incoherent, no sleep during the night. On the seventh, all the symptoms exacerbated; urine of the same characters; much talking, and he could not contain himself; the bowels being stimulated passed a watery discharge with lumbrici:* night equally painful. In the morning had a rigor; acute fever, hot sweat, appeared to be free of fever; did not sleep long; after the sleep a chill, ptyalism; in the evening, great incoherence; after a while, vomited a small quantity of dark bilious matters. On the ninth, coldness, much delirium, did not sleep. On the tenth, pains in the limbs, all the symptoms exacerbated; he was delirious. On the eleventh, he died.—Hippocrates

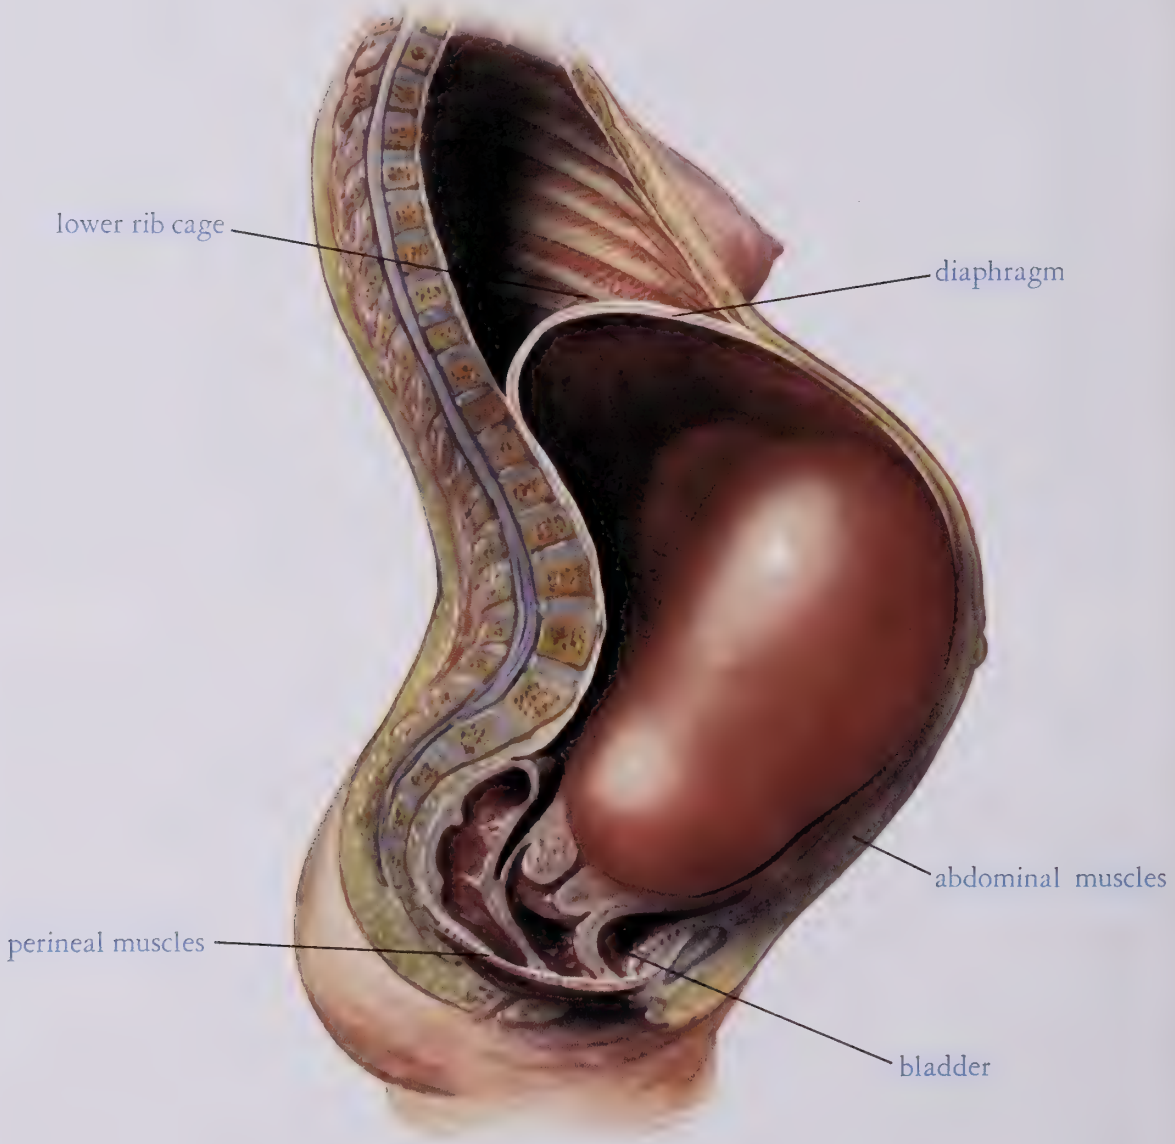
this issue: the cold in pregnancy...



The cold in pregnancy

Frederick W. Goodrich, Jr., M.D.
Senior Obstetrician and Gynecologist, Lawrence and Memorial Hospital, New London, Connecticut

Since pregnancy and the common cold are both ubiquitous, it is not surprising that they often occur at the same time in the same patient. Incidence figures are hard to come by, but the chances are very good that any given pregnant woman will have a cold at some time during the nine months of her gestation. When she does, she will tell you that it is the worst cold she ever had. It seems to last longer and the symptoms are more distressing than they are in the non-pregnant.

For purposes of this discussion, the common cold is considered to be the well-known symptom complex which includes sore throat, stuffy nose, and a cough. Febrile states or extension of the disease process into the lower respiratory tree are not part of the common cold and will not be included in this discussion.

The clinical picture of a cold in pregnancy can be confused by a long-known physiological phenome-

non. Kiesselbach's area in the nose (on the anterior part of the nasal septum above the intermaxillary bone) becomes engorged, apparently due to hyperemia induced by the increased estrogen level which accompanies pregnancy. The amount of congestion can vary in degree from woman to woman. Some have very little congestion, others will have occasional nosebleeds from this area, still others will have symptomatic congestion to the degree that they will complain of having a "chronic" or constant cold.

Less well recognized is the occurrence of this type of hyperemia in any part of the nasopharyngeal mucosa, again in varying degree. Such swelling often produces a postnasal drip which, the patient will state, is present only when she is pregnant. Patients who do not have symptomatic congestion ordinarily, will find that when they do get a cold, the symptoms last much longer than those of a cold usually do. Occasionally, this hyperemia is responsible for closure of the medial end of the Eustachian tube; such patients will complain of "plugging" of the ears. Inspection of the ear drum will show a depression which confirms the presence of Eustachian closure rather than wax in the canal which is the patient's diagnosis. Symptoms related to this physiological congestion are more apt to occur in heavier smokers or those who have a history of allergic rhinitis, just as are the symptoms of the common cold. And when the cold does occur in pregnancy, the symptoms are worse because of the underlying congestion.

The pregnant woman with a cold is miserable for other reasons, dependent somewhat on her parity and the length of her gestation. As parity increases, so also does the relaxation of the abdominal and perineal musculature. The uterus, lying against a slack abdominal wall, and bearing down on relaxed perineal muscles, acts like a piston when the patient coughs, sneezes, or even blows her nose, pushing down on the bladder. Stress incontinence during colds is almost the rule.

As the length of gestation increases, so does the size of the uterus. As it grows, it pushes the abdominal contents above it and elevates the diaphragm. This results eventually in a lateral displacement of the lower rib cage, often to a point at which the patient will complain of soreness in this area. If such a

timed to work while your patient does

A study begun in 1966 by the Department of Otolaryngology, Greater Baltimore Medical Center, has accumulated evidence that documents the effectiveness of Triaminic's timed-release action in the treatment of nasal congestion.

With its balanced formulation of an oral nasal decongestant and two antihistamines, Triaminic effected partial or complete relief in more than 82% of the 85 subjects treated. Clearing nasal obstruction. Reducing turbinate swelling. Making breathing easier.

It's a comforting thing to know that Triaminic really works.

Triaminic® *timed-release tablets*

Each timed-release tablet contains:

Phenylpropanolamine hydrochloride	50mg.
Pyrilamine maleate	25mg.
Pheniramine maleate	25mg.

Side effects: Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. Precautions: The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

(Advertisement)

patient has a cold, the coughing and sneezing will exaggerate this soreness. The diaphragmatic restriction caused by the enlarging uterus also makes breathing more difficult, particularly when the patient lies down. A cold compounds this difficulty.

Treating a cold in pregnancy requires two additional considerations. The patient should be told that the symptoms may last longer lest she become discouraged, and she should be reassured that the treatment will not damage the fetus. Although there are still some women who seem blissfully ignorant regarding matters of health (and these need to be cautioned not to take medication recommended by friends), most of our maternity patients are aware of the thalidomide tragedy. These women need constant reassurance that the symptoms of a cold can be treated, and that the medication is safe. Fortunately, many of the drugs which are of benefit have been in use long enough and widely enough so that such a statement can be offered. Occasionally one encounters a patient who is so anxious to avoid medication that she is extremely reluctant to take anything at all. Since cold is self-limited, it seems reasonable enough to give such a patient the choice and not to force drugs on her if she is obviously afraid of taking them.

The most distressing symptom of the common cold is the nasal congestion. This can be mitigated by the use of a decongestant which will help reduce the postnasal drip and the coughing caused by it. The kind of a cough which is described as a "tickling" in the throat and which is apt to occur when the patient goes to bed is usually due to nasopharyngeal congestion rather than inflammation in the lower respiratory tract.

There are many cough mixtures available. Most contain an antihistamine, a decongestant, and a cough "suppressant." Should cough suppression be desirable, it is important to remember not to use both a decongestant tablet and such a cough mixture as the patient would be getting a double dose of the decongestant. With some patients, the placebo effect of a cough syrup may be important and a liquid preparation might be substituted for an oral tablet.

For a sore throat, candy drops or lozenges at frequent intervals are soothing. It is not only unnecessary but unwise to use antibiotic lozenges or drops. The use of antibiotics in an uncomplicated cold is contraindicated and should be scrupulously avoided.

In summary, a cold in pregnancy is more severe and longer lasting. The treatment of the symptoms with local and systemic decongestants will make the patient more comfortable.

Apparently the cold is so common in pregnancy that it has received very little attention in the literature. References are almost non-existent and the few which are available add little to the common knowledge, are out-dated, or are not helpful. Thus the usual bibliography is not appended.

Relieve his sniffles, her concern, and about half your phone calls. Tell her to get "The Orange Medicine"

Triaminic® syrup

Each teaspoonful (5 ml.) contains:

Phenylpropanolamine hydrochloride	12.5 mg.
Pheniramine maleate	6.25 mg.
Pyrilamine maleate	6.25 mg.

For nasal congestion you can bring quick, lasting comfort to your little patients with Triaminic Syrup. You may occasionally encounter these side effects: drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. Precautions: the possibility of drowsiness should be considered by patients engaged in mechanical operations requiring alertness. Use with caution in patients with hypertension, heart disease, diabetes, or thyrotoxicosis.

Law and Medicine

Legal Immunity and Progress*

IN THE HIGHLY organized interdependent society of our time the three disciplines, medicine, law, theology, are more closely entwined than ever before. The medical breakthrough developed in the laboratory today may well become the standard by which the doctors' conduct is judged legally tomorrow. The life reclaimed tomorrow from the ravages of what is considered a terminal disease today presents theological and legal problems never before raised.

It has been generally true that society places the scientific advancement in a philosophical and legal perspective only after the potential consequences of the breakthrough are understood. However, today the *lawyer* and the *theologian* can no longer go about the leisurely development of their systems which have been historically valid. Since today's new clinical technique follows hard upon yesterday's laboratory discovery, the lawyer and the theologian must be ready to reinterpret their systems and revise their axioms to serve a society which *will* avail itself of new medical techniques whether the law and the church be ready or not.

The lawyer should attempt to constantly form, reform, assess, reassess, postulate and repostulate rules of practice and standards of conduct which will assist the profession as it moves ahead. The law, if it serves its function, will give the doctor a framework within which he may define the permissible limits of his new techniques and will also provide some type of reliable measuring device by which he can judge what is expected of him. If the law does this, then it has at least performed part of its function not only to the medical profession but to society in general.

As the medical profession moves into new areas of treatment and techniques, the legal institution must not go along merely as a wagging tail but must also serve as a guardian and conservator of the older principles which, if retained, will assist the inevitable progress of science. Indeed the law must continue to serve as a stabilizing device giving order and form to progress without impeding its advance.

Physician's Judgment

Foremost among the now accepted principles which must be jealously preserved is the immunity of the physician's judgment.

No Liability for Error in Judgment

Historically it has been the law that a doctor cannot be held for errors of judgment where there is a reasonable doubt as to the nature of the condition and the best method of treatment. A physician entitled to practice his profession, possessing the requisite qualifications, and applying his skill and judgment with due care, is not ordinarily liable for damages consequent upon an honest mistake or an error in diagnostic judgment, in prescribing a treatment or determining upon a certain operation. This principle must be retained. Medicine will continue to be as it has always been—an inexact science dealing with the most complex of mechanisms.

*Presented at the Annual Meeting of the Minnesota State Medical Association in Duluth, May 16, 1967.

Guarantee in Medicine Impedes Progress

A physician cannot guarantee results nor should that be expected of him. If the doctor is to become the guarantor of his treatment, if he is to be held legally responsible for a correct judgment on all occasions, then there will be no progress. The physician will never dare exercise that judgment which makes the practice of medicine the art that it is. Experimentation and innovation will be dead, and the healing art will stagnate in timidity and reserve. If the law allows this, it will surely have failed. Only when the doctor is free to exercise his best judgment can the new techniques become tomorrow's standard procedures and society become the benefactor of progress and discovery.

Failure to Cure

Together with the preservation of the free exercise of judgment, the law must not allow a failure to cure to become the foundation for a presumption of negligence. That is, the medical profession must not become burdened with the doctrine known in the law as *res ipsa loquitur,** where the physician is exercising his medical judgment with skill. As science advances and the miraculous recovery of today becomes the commonplace cure of tomorrow, there may be temptation to embrace this doctrine by those unaware of its implications. It is the law in this state, as well as in most states, that a person bringing action for the neglect of a physician to use the degree of care, diligence and skill required must prove such neglect. As the law now stands, no presumption of negligence arises from the fact that an operation or treatment does not result in a cure. In other words, success is not guaranteed and the lack thereof is not evidence of culpability. Negligence must not be presumed from results. Otherwise the doctor would work under a constant and intolerable threat of failure and would ply his art with only the most conservative and accepted tools and techniques. Because of the threat of one failure, one hundred successes might be denied. If the law forces medical science to work within such a straitjacket, it will again have failed in its obligation both to medicine and to society in general. Progress will cease, innovation and experimentation will wither and die.

Standard for the Region

If medical science is to continue to progress it is important that the physician continue to be judged by the standard of learning and skill possessed by the average number of his profession in good standing in his locality. This has historically been the standard by which the physician has been judged and it is the only workable standard.

The Country vs. the Metropolitan Doctor

The country doctor with his less extensive resources and facilities and with the myriad demands upon his time has never been held to the standard of the physician working in the metropolitan area close to the facilities of medical schools, blood banks and large urban hospitals. The general practitioner has never been held to the same standard in treating a fracture, as has an orthopedist. The reasons are obvious.

Still, with the increased urbanization that inevitably will come in the next few years, with the ever-developing systems of communication and transportation which dissolve the barriers of time and space, there may be a

*See Test Your Word Score Page 53.

temptation to alter the historic standard. The rural doctor who is only minutes away from the urban center may come to be expected to possess the same degree of skill and learning as his colleagues in the city. As most doctors move into metropolitan areas and specialize, there may be a temptation to adopt a common norm by which all will be judged—including those who choose to remain in rural areas and serve that segment of the population. If the country doctor is to be held to the same standard of skill as the practitioner on the university medical school staff, then surely he will never attempt to use the techniques which that urban practitioner has developed. It is only where the rural physician knows that he will not be judged by the urban standard that he will bring to his patients the advances that the urban specialist with his more extensive facilities has developed.

Free Choice of Physician

The patient has always had the right to refuse to follow a course of treatment and to terminate the doctor-patient relationship at any time. If new techniques and methods are to flourish the patient must be free to disregard his doctor's orders, to walk out of the hospital or the doctor's office, and to fire his physician without cause. With the inherent risks and hazards of such developing techniques as kidney transplantation, kidney dialysis machines and heart surgery, the right of the patient to refuse such treatment must be guarded. The real promise which medical advance holds will become apparent to a public which chooses of its own accord to accept the risks.

Accompanying the right of the patient to balk at progress must be an equal protective measure for the physician. Where a patient refuses to submit to the reasonable treatment prescribed, the onus must be on the patient and not on the doctor.

Comments

Such then are at least some of the traditional foundation stones which the law long ago placed beneath the practice of medicine, and they must remain if the institution of the law is to continue to assist the medical profession. Finally, however, both the lawyer and the doctor must share a common ideal if each is to lend his unique talents to the advancement of the healing science. Both must carry a fierce and dedicated commitment to the prolongation of life. The doctor must not hesitate or reject application of new methods and techniques that will assist in the prolongation of that life to which he has committed his talents. It is at this point then that the lawyer must demonstrate his commitment to the same ideal. For only the lawyer, using the techniques available to him, can urge upon society the legal protections and safeguards which will free the doctor to more vigorously pursue that goal to which he has dedicated his professional life. Confident that he is practicing his profession in a society in which the law recognizes that with progress come risks, and that with the exercise of judgment come failures, the doctor will more eagerly approach his task. If the lawyer has assisted in some small way in creating a legal framework within which the doctor can practice with confidence, then the lawyer goes where the doctor goes—toward future progress.

An English Court said in 1954: "We should be doing a disservice to the community if we imposed liability on hospitals and doctors for everything that happens to go wrong. Doctors would be led to think more of their own safety than of the good of their patients. Initiative would be stifled and

confidence shaken. A proper sense of proportion requires us to have regard for the conditions in which hospitals and doctors work. We must insist on due care for the patient, but we must not condemn as negligence that which is only misadventure."

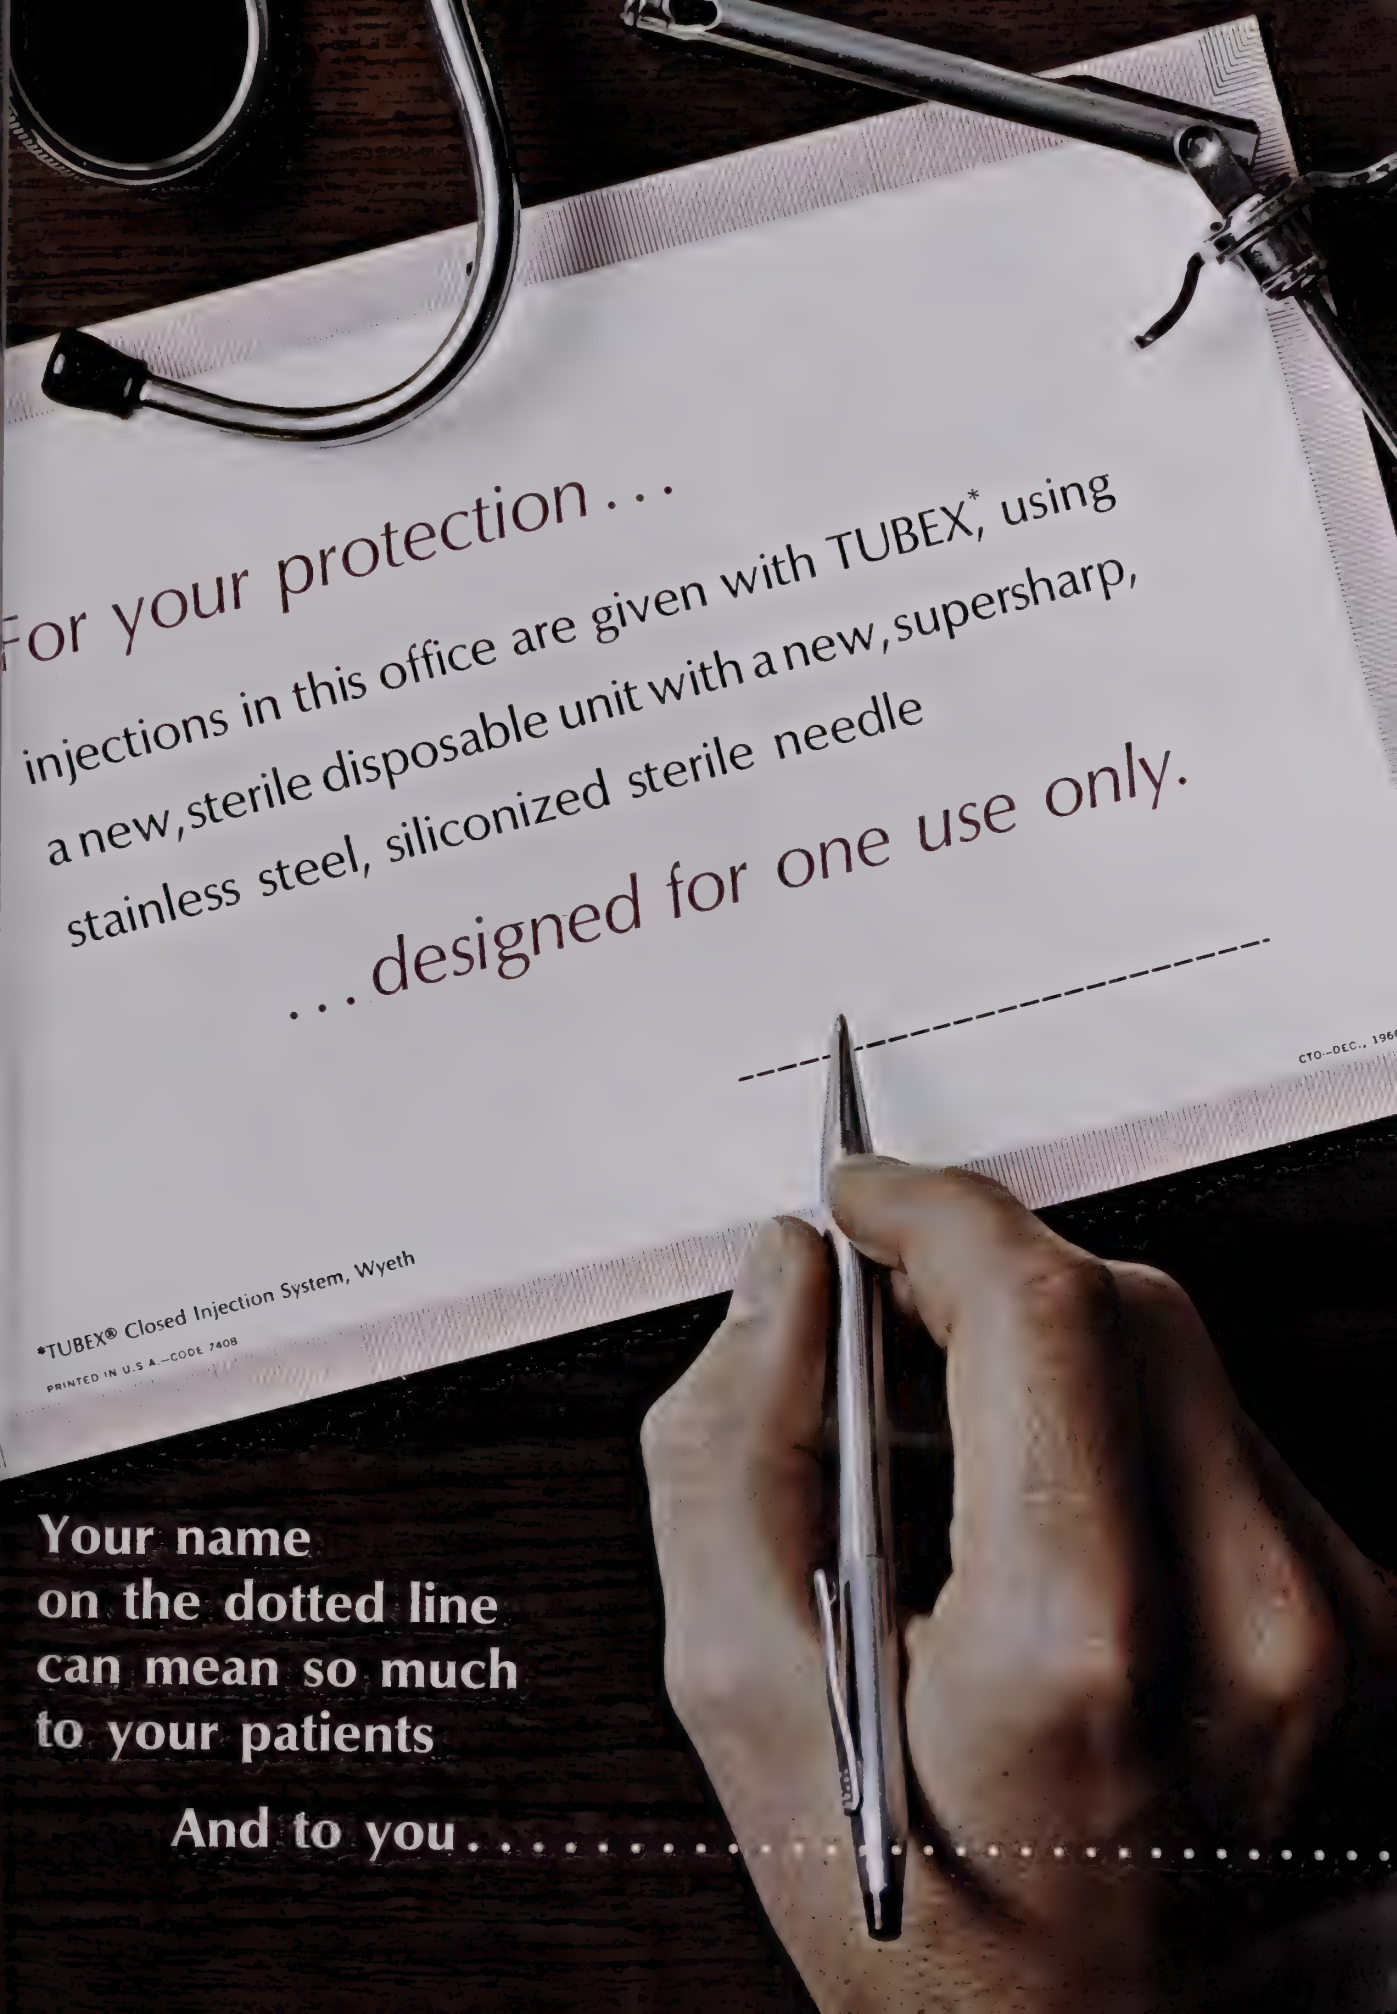
Pandora's Box

By the conquest of disease Europe and the world entered the bacteriological era. The pressure of disease was removed and its rods of chastisement broken. The ills that once flew out into the world from Pandora's Box were imprisoned once more and kept in safe custody.

Has man, with his conquest of disease, interfered without authorization in the cosmic plan? This question must be taken seriously. Were diseases designed to keep human propagation within bounds, to sweep away surplus populations and ensure living space in the world? If that be the case the balance has been upset by the conquest of disease. The Malthusian Law has proved its validity and the dangers prophesied are already looming on the horizon. Admittedly Europe could deport its huge population surplus to the new continents of America and Australia, but the peoples of Africa and Asia, who were also once condemned to a slow but certain death through epidemics, have been freed from the pressure of disease and have been awakened from their lethargy. Their vitality is increasing and they are shaking off the yoke of colonialism which brought them salvation from disease. Modern medicine applied to these people will, within a few generations—unless technology opens up new sources of life—render the earth uninhabitable. Asia alone in the year 2000 will number 2,000,000,000 and by its very mass will overshadow the people of Europe. The gift that Europe has given the world and the knowledge that has enabled it to overcome great dangers may possibly prove its own undoing.*

H. S. Glasscheib, M.D.: The March of Medicine, 1964.



Medical Men on Postage Stamps

Hermann Boerhaave (1668-1738), Dutch physician and medical theorist and writer, is regarded as the first great clinical or 'bedside' teacher. He is reputed to have so raised the standards at the University of Leiden that students flocked to it from all over Europe. In 1938 The Netherlands commemorated his medical contributions by issuing a postage stamp in his honor.

William Harvey (1578-1657), English physician and anatomist who demonstrated that the arteries contained blood instead of air and originated the theory of the circulation of the blood, was honored by Russia on a special postage stamp issue in 1957.

Grand Rounds

Transvenous Pacing of the Heart*

M. THOMAS STILLMAN, M.D.
Medical Resident

THE TECHNIQUE of transvenous pacing of the heart has become an important consideration in the management of patients with symptomatic heart block. Initially this technique was considered only in the temporary management of symptomatic A-V block associated either with Stokes-Adams syndrome or other complications. Although its short-term use remains as a primary indication, recent work has suggested catheter pacing for long-term therapy. This paper is designed to discuss the indications, technique, complications, and effects of transvenous catheter pacing and deals with the permanent implantable pacemaker only in passing. The paper also reviews the experience of transvenous pacing at Hennepin County General Hospital in ten patients.

In 1951 Callaghan and Bigelow[1] used a transvenous catheter electrode in dogs to maintain the heart rate by means of electrical pacing. The catheter was placed in the area of the sino-auricular node via the external jugular vein. In 1958, Furman and Robinson[2] described a method for catheter pacing in animals with experimentally produced heart block. Furman and Schwedel[3] reported the clinical use of transvenous pacing in two cases in the therapy for Stokes-Adams syndrome, using unipolar electrodes. Parsonnet and others[4] introduced the bipolar electrode catheter for clinical usage in patients with heart block. In the past five years, other investigators have reported the clinical usage of transvenous pacemakers.

It is generally accepted that the use of a transvenous pacemaker should be considered in high-grade or complete heart block in which a bradycardia or a ventricular arrhythmia leads to symptoms of the Stokes-Adams syndrome.

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, March 21, 1967.

Etiology

Coronary Disease

The etiology of complete heart block is poorly understood. The primary cause was associated with coronary heart disease in a chronic form, or in association with hypertension or acute myocardial infarction (60 per cent).[5]

Hypertensive Disease

The other etiologic conditions included hypertensive heart disease, rheumatic cardiovascular disease, congenital heart disease, and others of unknown etiology. Friedberg points out that there is not always a correlation between the pathology of the conduction system in complete heart block and pathology found within coronary arteries. Coronary disease may not be a causative factor but rather a coexistent one.

Mechanical Stress

He feels an alternate theory is that prolonged mechanical stress with secondary fibrosis results in lesions within the conduction system resulting in complete heart block, a theory most applicable to chronic heart block. Carleton and others[6] include acute myocarditis as etiology of heart block, the probable cause in one of our cases at this hospital. Table 1 gives a more complete account of causes of heart block reported in the literature.

*Friedberg, C. K., Donoso, E., Stein, W. G., Ann N Y Acad Sci 111:836, June, 1964.

Complications

No matter what the etiology may be, patients with complete heart block must depend upon the ability of the conduction system below the block to initiate ventricular impulses at a sufficient rate. A slow idioventricular rhythm associated with a complete A-V block may result in three clinical complications:[6]

1. The shift in or less frequent depolarization of the idioventricular pacemaker producing extreme bradycardia or complete asystole.
2. Repetitive episodes of ventricular tachycardia or ventricular fibrillation.

3. Intractable congestive heart failure.

Either of the first two complications may impair cerebral blood flow and produce the episodic syncopal-convulsive symptoms that characterize the Stokes-Adams syndrome.

Indications

The indications for use of a transvenous pacemaker may be divided into two categories, the short-term and the long-term usage.[7-29]

Short-Term Indications

Furman[8] summarized the short-term indications as follows: (1) Initial control of symptomatic heart block complicating acute myocardial infarction. (2) Control of heart block with complicating congestive heart failure. (3) Control of heart rate during surgery, including the implantation of a permanent pacemaker. (4) Control of heart rate during periods of permanent pacemaker failure. (5) Control in the patient who reverts to a conducted rhythm after a brief period of pacer therapy.

The patients in the last three categories experience Stokes-Adams symptoms at the time of their heart block; whereas the patients in the first two categories may or may not experience these symptoms. This paper will discuss the first category in more detail in view of its somewhat controversial nature.

The use of transvenous pacemakers in *acute myocardial infarction* with complicating complete heart block has proven to be an important adjunct to therapy[16-20,22,23,27]. Paulk and Hurst[23] pointed out in their study that with the advantage of recent electrical monitoring, our awareness of the incidence of complete heart block occurring in acute myocardial infarction has risen from 1.5% to 8%; their own incidence was 3.4%. The mortality has ranged from 40 to 100 per cent. Friedberg[5] points out that the heart block is almost always transient and disappears within seven to 14 days. Usually minimal lesions are seen in the conduction system at the time of autopsy, suggesting an ischemic or inflammatory etiology for the block. The transient nature of this block has led some investigators to believe that cardiac pacemakers are not indicated in this condition. In 14 of 18 patients reported by Courter and others[30] the heart block disappeared within six days. Jackson and Bashour[31] reported 27 of 32 patients reverting to a sinus rhythm by the fifth day. They pointed out that left heart failure was common but Stokes-Adams symptoms were uncommon in this type of heart block.

There still remain some patients in whom the use of a pacemaker may be indicated. Friedberg[5] considered three different types of *patients that may be predicted to have an unfavorable course* and in whom pacing may be needed. These included: (1) Patients with heart block and anterior myocardial infarction. (2) Patients with heart block and myocardial infarction whose electrocardiogram shows aberrant QRS complex. (3) Patients with associated Stokes-Adams attacks.

Cohen and others[32] reported a 75% mortality rate in 16 cases of anterior myocardial infarct with heart block as opposed to a 37% mortality rate in the inferior type of infarction with block. Since the right coronary artery (the supply to the A-V node in 90% of cases) is usually involved in an inferior infarct, associated heart block is due to ischemia and is transient. The block associated with an anterior infarct (involvement of the left coronary artery) is due to severe infarction of the septal muscle causing destruction within the conduction system. Cohen[32] pointed out that an aberrant QRS

complex suggested a pacemaker below the bifurcation of the Bundle of His. This type of complex was associated with an 80% mortality, while the patients with a QRS complex above the bifurcation showed a 48% mortality. Friedberg[5] postulates that a right coronary thrombosis (diaphragmatic-type infarct) will affect the A-V node; while the left coronary artery (anterior-type infarct) will affect the septum and damage both bundle branches, giving rise to an aberrant QRS complex from a lower idioventricular pacemaker. Varying results of pacing during acute infarction have been reported. Bruce and others[20] reported a reduction in mortality rate to 14% in seven patients. Paulk and Hurst[23] reported a series of 43 patients with heart block associated with myocardial infarction who had transvenous pacing. Seventy-five per cent of the patients had inferior infarctions, 7% had anterior, and 18% had both types. The overall mortality rate was 44%, thus remaining quite high. The degree of mortality was related to the severity of associated congestive heart failure. Similarly, the presence of shock or cardiac arrest was related to the mortality rate. The duration of active pacing ranged from one to twenty-one days in the survivors (56%). The authors feel that pacemaker insertion is not an innocuous procedure for a patient with a myocardial infarction. They prefer waiting until complete heart block intervenes. In 1,500 cases of myocardial infarction, these authors found the incidence of second degree heart block to be 8.7%, less than half of which continued into complete heart block. They also found that 25% of the survivors had a persistent complete heart block, a figure higher than previously reported. The authors attributed this to the survival of patients who would otherwise have succumbed from atrioventricular nodal infarction. It has also been pointed out that drugs such as digitalis or Pronestyl that might otherwise be contraindicated in heart block may be used in association with a transvenous pacemaker. It would appear that the role of a catheter pacemaker during acute myocardial infarction complicated by complete heart block becomes valuable provided its use is limited to certain clinical situations.

Transvenous pacing on a short-term basis not involving acute myocardial infarction is well reviewed by Yuceoglu and others.[7] The diagnosis of arteriosclerotic heart disease (non-acute) was made in 73 out of 78 patients studied. The various rhythm disturbances are summarized in Table 2. Immediate, satisfactory pacing was obtained in all but one patient. Duration of pacing was from one to fourteen days. This procedure was continued until optimal clinical improvement or before implantation of a permanent pacemaker.

TABLE 2*
Indications for Transvenous Pacemaker in 78 patients

	Number of cases
A-V block associated with Stokes-Adams syndrome:	
Ventricular standstill	30**
Ventricular tachyarrhythmia	27†
Ventricular standstill with ventricular tachyarrhythmia	6
Regular sinus rhythm with episodes of ventricular flutter-fibrillation unresponsive to Pronestyl or quinidine	1
Extreme regular sinus bradycardia with Stokes-Adams seizures due to cardiac standstill	1
A-V block with intractable congestive heart failure due to slow rate (low cardiac output)	12
Atrial fibrillation with extreme bradycardia, ischemic brain syndrome, and heart failure	1
Total	78

**Two with severe congestive heart failure, two with severe cerebral ischemia.

†One with severe congestive heart failure.

Long-Term Indications

With this procedure there are certain advantages, the primary one being the avoidance of a thoracotomy in the elderly patient who cannot tolerate such a surgical procedure. Long-term catheter pacing has also been recommended in the very young patient with congenital heart disease with block and in those patients who refuse a thoracotomy. Since December of 1963, Chardack and others[10] have treated 31 patients with a bipolar endocardial electrode catheter connected to an implanted pulse generator placed into the soft tissue below the clavicle.

Procedure

This paper deals primarily with techniques used at Hennepin County General Hospital. The externally placed pacemaker used has been a battery-powered pulse generator manufactured by Medtronic Inc., Minneapolis, Minnesota. Milliamperage as well as rate may be adjusted on the unit. The catheter used is a bipolar type with platinum terminals welded to stainless steel coils running in separate lumina within the catheter to the pulse generator. Stiffness and slight curvature are given to the catheter (needed for insertion and manipulation) by means of stainless steel stylets placed into the lumen of the coils. It is felt that the bipolar type of catheter electrode is superior to the unipolar type[4,11,15,33] which required an indifferent electrode placed in the subcutaneous skin of the chest wall. Patients complained of pain in this area during pacing. Furthermore, it was found that the bipolar electrode catheter was easier to position and did not require the degree of myocardial contact needed in the unipolar type.[33] The need for anticoagulants was abandoned with the use of the bipolar type, and the incidence of infection was lower.[11]

An outline of the general technique recommended is as follows:

1. The patient is placed in a recumbent position with the head turned to the left or right and the shoulder elevated.
2. The root of the neck is prepared and the external jugular vein is exposed.
3. An electrocardiogram monitor is present.
4. An external pacemaker should be available, preferably strapped to the chest.
5. A cut-down is performed upon the right external jugular vein with ligation of the proximal portion.
6. The catheter is inserted under sterile conditions and directed under fluoroscopy into the apex of the right ventricle.
7. If the patient's condition permits, various positions and respiratory efforts are tried.
8. Voltage usually necessary to pace is less than one milliampere, and a one-to-one ventricular response is a check upon proper placement. As a margin of safety the voltage is generally increased to 1.5 to 2.5 milliamps.
9. The pacing rate most often used is 70 impulses per minute but may be increased to capture from and suppress all ectopic foci.
10. The catheter is sutured into place at the cut-down site and sterile dressings are applied.

Because of freedom of movement of the patient and less chance for displacement, the external jugulars are preferred. The internal jugular veins as well as the arm veins can also be used for placement. In patients who will

likely need permanent transvenous pacing, the right external jugular vein should be spared at the time of initial catheter placement for interim pacing. The success of transvenous pacing depends upon the proper placement of the electrode tip within the trabeculae at the apex of the right ventricle. When the desired position is obtained, the stylets are withdrawn to assure flexibility of the catheter. Within weeks, the catheter becomes covered by a continuous layer of fibrous tissue. Improperly placed catheters lead to pacemaker failures. Unstable positions of the catheter tip include: (1) Close proximity to the tricuspid valve with advancement into right atrium. (2) High position in the pulmonary outflow tract. (3) Loops or tension within the catheter.

If a great deal of manipulation of the catheter is required, prophylactic antibiotics may be considered. Various techniques are described for permanent placement of transvenous pacemakers but, in general, the endocardiac electrode is of the bipolar type and the pulse generator is smaller and implanted within the subcutaneous tissue under local anesthesia.[40]

Complications

Arrhythmias

In a study of 96 insertions in 78 patients[7] the most common catheter complication was the occurrence of arrhythmias during insertion. Other complications are listed in Table 3.

TABLE 3*
Electrode Catheter Complications

Arrhythmias during insertion:	
Ventricular tachyarrhythmia requiring defibrillation	19**
Ventricular standstill requiring external pacing	6
Perforation of right ventricular outflow tract	2
Possible perforation of great cardiac vein	1
Repositionings (11 patients)	19
Bleeding	2
Thrombophlebitis	1
Infection	
Local, at phlebotomy site (saphenous)	2
Sepsis	2
Ulcerative bacterial endocarditis (rheumatic heart disease)	1
Death during catheter insertion	4

*Yuceoglu, Y. Z., Lunger, M., and Dresdale, D. T.: Amer Heart J 71:9, Jan. 1966.
**Total of 9 patients: 4 times in one patient, and 8 times in another. Both patients survived.

Perforation

Perforation of the right ventricle has occurred less frequently with the recommendation to remove the stylets after placement of the catheter. In Table 4 Chardack and others[10] report 16% of the cases complicated by either perforation or disruption of the coils probably due to the retained stylets. Fort[34] reported two cases of perforation of the right ventricle in patients who suffered no ill effects. Retrospectively, the clues to perforation were difficulty of pacing and the presence of a systolic sound along the left sternal border. Moss and Rivers[35] point out the roentgenographic demonstration of change in position as a helpful aid in discovery. Nathan and others[37] reported a 20% occurrence of this complication. Although there appear to be a few deaths reported from this complication, some authors[13] feel that it necessitates the placement of the catheter in the outflow tract rather than the ventricular apex. It is felt that foreshortening of the apex-base distance during systole

requires a catheter to be sufficiently compliant laterally as well as longitudinally. Thrombotic attachment to the endocardium limits this compliance. In one of our cases at this hospital, perforation of the septum occurred secondarily to remanipulation of the catheter.

Malposition

Malposition within the ventricle requiring repositioning occurred in about 14% of the patients reported by Yuceoglu and others.[7] This is usually due to inadequate initial placement, loosening of the subcutaneous stay sutures or placement of catheter within the arm. Besides malposition of catheter, pacemaker failure may occur on the basis of electrical failure (battery or catheter), dominant spontaneous rhythm, and loss of myocardial reactivity. Gordon[28] presents an organized regimen to locate the source of difficulty, using cavity lead electrocardiogram patterns as well as roentgenographic procedures.

Infections

Infections did not seem to be a significant complication of transvenous pacing.[24,11] Isolated cases of bacterial endocarditis[7] have been reported, as in one of our cases. Schwedel and Escher[11] pointed out the increased incidence of infection occurring in those patients who undergo repositioning and excess manipulation of the catheter. In these cases it is best to remove the catheter and replace it with another. Local infections at the catheter site occurred in 33% of the cases reported by Furman and others.[8]

Thrombophlebitis or complicating thromboembolic phenomena did not occur with any significance, and there was no advantage in anticoagulant therapy.

Many authors report the dangers of ventricular fibrillation occurring with transvenous pacemaking. This arrhythmia occurs secondarily to the pacemaker stimulus falling within the vulnerable period following the preceding conducted or ectopic ventricular depolarization. Chardack and others[10] showed that a stimulus of the magnitude of 40 to 45 ma. is needed to produce such an arrhythmia in the vulnerable period. This represents a 10 to 20-fold greater stimulus than the pacer produces. There still exists the danger of a competitive rhythm occurring with pacemakers and the chance of a much greater stimulus such as a P wave occurring in the vulnerable period. It is this consideration that gave rise to the demand pacemaker.[36,38] In demand pacing, the delivery of an electrical impulse is coupled to the preceding QRS complex, and delivery of a pacer impulse takes place only when a preset time interval after ventricular depolarization has been exceeded. In other words, the pacemaker paces when the spontaneous rate is lower than the preset pacemaker rate. Demand pacing avoids unnecessary continuous stimulation of the myocardium.

Effects of Pacing

Hemodynamics

It is generally felt that electrical pacing gives immediate favorable results. The hemodynamics of the heart are improved with pacing. Escher and others[12] studied 27 patients with complete heart block with respect to hemodynamics while being artificially paced. None of the patients were in congestive failure. All showed reduced cardiac output at their slow idioventricular rates, but there was a marked difference in cardiac output from patient to patient. In about one third of the patients, a normal cardiac output was achieved, indicating the significance of heart rate alone.

Optimal Fixed Rate

The optimal fixed rate for maximum comfort appeared in the 70's. This correlated with the level at which most reached their greatest percentage of increase in cardiac output. These patients were able to tolerate increased rates to suppress ectopic beats. The inability to increase cardiac output with exercise is a limiting factor in fixed artificial pacemaking. It may be said that a normal cardiac output may be maintained by a healthy myocardium through a compensatory increase in stroke volume during heart block. A diseased myocardium may be incapable of showing this compensation such that changes in cardiac output are completely dependent on heart rate.

Many investigators have reported the use of drugs in the treatment of complete heart block, a subject beyond the scope of this paper.[41-43] Certainly such drugs as isoproterenol, epinephrine, steroids, chlorothiazides have their places in the overall treatment of complete heart block. There still remain the patients that are not responsive to drug therapy or develop the undesirable effects of these drugs. There are also the patients that have associated complications that need immediate resolution in which transvenous pacemaking may be life-saving. Karlson and others[21] report that in 47 patients with heart block and Stokes-Adams syndrome treated medically with isoproterenol, 70% continued to have Stokes-Adams seizures, 20% showed ventricular arrhythmias and 10% showed a good response. Chardack and others[10] compared the survival of 50 pacemaker patients on whom a two-year followup was available with comparable patients treated by drugs alone. With the exception of a 10% mortality rate associated with surgery, the per-cent survival after one and two years was significantly higher in the paced group of patients.

Our Results as of March, 1967

Our experience with transvenous pacemakers in 10 patients is summarized in Table 4. Twelve insertions were made in 10 patients, all of whom had complete heart block. The etiology in 5/10 was probably arteriosclerotic heart disease; 4/10 acute myocardial infarction; and 1/10 probable myocarditis. All were paced on a short-term basis ranging from one hour to 13 days.

Complications

Complications of pacing included: (1) 4/12 insertions: difficulty with technique. (2) 1/12 insertions: infection and septicemia. (3) 1/12 insertions: perforation of septum. (4) 7/12 insertions: poor pacing.

Mortality

The results showed that 3/10 patients recovered with a loss of the complete block; 5/10 patients went on to have a permanent pacer; 2/10 patients died, both from acute myocardial infarcts.

Summary

Transvenous pacemaking should be an important consideration in the treatment of symptomatic heart block. Its primary indication has been in the presence of complete heart block with Stokes-Adams symptoms or other resulting complications such as refractory congestive heart failure.

TABLE 4

Name	Age	Sex	Indications	Days Paced	Pacer In place	Complications	Results
M.B.	53	M	Inferior M.I. with complete heart block; poor response to Isuprel.	6	11	Difficulty rt. jug. vein; local infection cutdown site; unable to remove catheter.	Spontaneous resolution; 2° to 1° block in 7 days.
R.B.	64	M	Anemia; 2° heart block with RBBB; documented episodes of asystole –3°.	8 48	8 48	Complete asynchrony 2° to poor catheter placement. Infection cutdown site that advanced to septicemia and bacterial endocarditis; perforation of septum; 2nd catheter placed.	Permanent pacemaker.
A.M.	74	M	ASHD; old ant. M.I.; Acute inf. M.I.; RBBB-AV dissociation.	1 hr.	10 hrs.	Unable to locate rt. jug.—rt. arm vein.	Died within 24 hrs.
C.H.	20	M	URI for 7 days; Stokes-Adams attack –3° heart block, pulse –30; no response to Isuprel; viral myocarditis.	6	10	Poor pacing—required remanipulation.	Spontaneous recovery.
J.L.	79	M	Stokes-Adams syndrome—complete 3° block. Pulse 44/min.	13	13	Rt. jug. unsuccessful—left jug.; Completion with sinus pacer.	Permanent pacer.
B.B.	80	M	Stokes-Adams syndrome; Pulse 36/min.	5	5	None.	Permanent pacer.
C.L.	61	M	ASHD; Acute inf. M.I. 1° block –3° block on day 3; poor resp. to Isuprel; CHF.	1½	7	Asynchrony.	1° block on day 5; Transferred after 18 days.
C.S.	74	M	Stokes-Adams syndrome; Isuprel ineffective; poor sensorium.	9	14	Sinus pacemaker completion left cephalic vein.	No change in sensorium. Discharged 2:1 block.
			Stokes-Adams syndrome	4	4	Unsuccessful l. jug. l. brachial; Missed beats.	Permanent. Died 3½ mo.
L.B.	62	M	Auto trauma; acute inf. M.I.; Stokes-Adams symptoms with 3° block; Intractable CHF.	0	8	Catheter in pulm. outflow tract—never paced.	Died. Post: Rt. coronary occlusion.
A.P.	74	F	Stokes-Adams with 3° block.	8	8	Difficulty pacing.	Permanent.

Short-term pacing entails control of heart rate during an acute myocardial infarct, acute congestive failure, preparation for/or during surgery, permanent pacemaker failure, or periodic rhythm disturbance. The use of pacing in acute myocardial infarction is controversial. The known incidence of complete heart block in acute myocardial infarction is increasing and the mortality remains quite high.

Long-term transvenous pacing has been used in the patient who cannot tolerate a thoracotomy.

Primary complications have included arrhythmias during insertion, perforation, malposition, pacemaker failure and infection. The danger of ventricular arrhythmias, primarily fibrillation, has increased interest in demand pacemaking. Generally there is improved hemodynamics with pacemaking. Overall evaluation shows pacing to be superior to drug management in complete heart block.

Transvenous electrical pacing of the heart is a relatively safe, effective, reliable, and oftentimes life-saving measure for immediate as well as for long-term control of symptomatic heart block.

Case Report

A 74-year-old white female with a six to seven-year history of hypertension suffered some syncopal episodes during the week prior to admission, causing some minor head trauma. The patient was admitted after loss of consciousness while driving her car. Her pulse on admission was 40 and her blood pressure 150/80. Documentation of episodic, symptomatic ventricular fibrillation associated with complete heart block was obtained on electrocardiogram. A transvenous pacemaker was inserted through the right external jugular vein 24 hours following admission. The patient was paced at 60 to 70 beats per minute at 1.5 to 2 milliamps, with definite subjective improvement. On the fourth hospital day of pacing she failed to pace periodically, the failure seemingly related to change in position, and she was having multiple premature ventricular contractions during asynchrony. A gradual increase to 10 milliamps was required for pacing by the eighth day. On the ninth hospital day a permanent epicardial pacemaker was implanted. The patient did well following surgery and was discharged on the twenty-sixth hospital day.

Thirty-First Annual Meeting

The New Orleans Graduate Medical Assembly

The thirty-first annual meeting of The New Orleans Graduate Medical Assembly will be held March 4, 5, 6, 7, 1968, headquarters at The Roosevelt Hotel.

Nineteen outstanding guest speakers will participate and their presentations will be of interest to both specialists and general practitioners. The program will include fifty-one informative discussions on many topics of current medical interest, in addition to a clinicopathologic conference, symposia, medical motion pictures, round-table luncheons, and technical exhibits. This program is acceptable for thirty-two (32) elective hours by the American Academy of General Practice.

An interesting and enjoyable program of entertainment for visiting ladies has been planned.

Of special interest will be a one-day pre-Assembly symposium scheduled for Sunday, March 3, on "Sexual Problems in Clinical Practice." Six papers, together with a panel discussion, will be presented by six authorities on this subject.

Abstracts, Briefs and Commentaries

SQUAMOUS CELL CARCINOMA OF THE PYRIFORM SINUS

During a twenty-year period, 1940-1960, 119 patients completed the recommended treatment for squamous cell carcinoma of the pyriform sinus. The patients were on one of the head and neck services of the Roswell Park Memorial Institute.

Sixty-six patients were treated by radiation alone during the first 16 years. No surgery was done for this type of lesion during that period. The five-year survival was 3%. When broken down into three periods of time to eliminate possible differences in irradiation technique the survival rate remained the same.

Fifty-three patients were diagnosed and treated from 1954 to 1961, twenty-six of them by radical surgery consisting of total laryngectomy, partial pharyngectomy, and radical neck dissection. The five-year survival in this group was 20%. Metastatic disease was found histologically in 82% of patients treated by radical surgery.

THE COMMUNITY-UNIVERSITY HEALTH CARE CLINIC

The Community-University Health Care Clinic initiated in July, 1966, as a University Community Program is a pilot project within a larger Children and Youth project administered by the Minneapolis Health Department.

Situated in an urban area unusually needful of a wide range of health care, the primary goal of this program of comprehensive social, physical and mental health care is education of resident physicians, medical and dental students and students of the allied health disciplines. Collecting data for research in associated urban problems is a vital secondary goal.

The project aims to provide care to eligible children from birth through high school in an area defined by the geographical confines of Seward, Adams, and Greeley Elementary School Districts in South Minneapolis. Of

the 7,200 children within the area approximately 2,900 have been defined as eligible because of low family income. A preliminary survey carried out in the summer of 1966 revealed that 94% of the area children under five years of age had never seen a dentist, 53% of the whole 7,200 had never been treated by a private physician and only 9% had received care at the Hennepin County General Hospital.

A high incidence of psycho-social, speech, language and auditory disability accents the need for preventive measures, as well as long-term care, involving the project staff, citizens' groups and schools.

A clinic building converted from an apartment house near the geographical center of the area opened in February, 1967. A substation staffed by public health nurses from the Minneapolis Health Department occupies the fourth floor. The staff is on call during non-office hours for the patients enrolled, with hospitalization when necessary at one of the adjacent cooperating community hospitals.

The patient population currently under care has grown mainly from neighbor or self-referral, with some referral from the cooperating public health nurses.

The recent formation of a University Hennepin County Medical Society liaison committee to work with the project staff will do much to further develop common interests in the promotion of suitable training opportunities for professionals desiring a career in clinical practice.

METHODS OF BIRTH CONTROL*

Birth control is an accepted technique of preventive medicine—its simple goal: every pregnancy wanted and planned. Physicians should be equipped to be competent advisors concerning the effects of age, parity, and pregnancy interval on pregnancy outcome, as well as effective and safe methods of birth control.

If the couple is young, the physician may counsel postponement of pregnancy until one or both partners have completed their educations. He may also advise contraception if his experience leads him to believe that adjustment is virtually always necessary in early marriage and that it can be better made by the couple before than during a pregnancy.

The best allies of successful pregnancy are youth, normal germ plasm, sound health, and good medical care. The optimum years for childbearing are ages 20 to 30 for the mother. After the father is 45 both stillbirth and congenital malformation rates rise. Beyond the fourth child maternal and perinatal mortality rates rise slowly through para six, moderately through para eight and relatively rapidly thereafter. The best pregnancy interval from the viewpoint of infant survival is two to three years between the end of one pregnancy and the beginning of the next. The physician knowing the health of the woman should advise against further pregnancies, if in his judgement medical contraindications exist.

Contraception is a rapidly developing field and the physician must be

*Presented at the Minnesota State Medical Association Annual Meeting, Duluth, Minnesota, May 16, 1967.

sufficiently conversant with it so that he may offer the individual couple several methods of birth control from which to choose. No single method is satisfactory for all couples under all conditions and circumstances. The doctor should frankly inquire into the sexual adjustment of couples under his care, and if he thinks their method of contraception contributes to lack of sexual satisfaction in either husband or wife, he should advise the trial of a different technique.

The author classifies contraceptive techniques in six categories on the basis of effectiveness when used correctly:

Class I — Gestagens by mouth or injection
Class II — Intrauterine device, condom, diaphragm and cervical cap
Class III— Aerated intravaginal foam, rhythm when practiced with the aid of basal body temperature
Class IV—Ordinary intravaginal chemical, jellies, creams, tablets, suppositories
Class V — Coitus interruptus, rhythm when practiced by calendar
Class VI— Post-coital douche

Since there is such latitude of choice among the first three classes, it seems pointless for the physician to recommend methods listed in categories IV, V, and VI.

The advantages, disadvantages and safety of the various methods listed in the first three categories will be discussed.

DAMAGES UPHELD

Damages for 1.5 million dollars were awarded a woman in Miami, Florida, against two physicians and a hospital. She was paralyzed from the neck down following an operation for varicose veins and hemorrhoids. The type of anesthesia was not stated. The award was made by a Circuit Court Judge.

Note: How many physicians or clinics could survive such a judgment even with unusual help from their insurance coverage?

WHAT DOES GALVANIC SKIN RESISTANCE DEMONSTRATE ABOUT THE EFFECT OF VALIUM (diazepam)?

Galvanic skin resistance...one measure of the Valium (diazepam) effect in reducing the somatic response to acute stress[1,2]

The subjective value of Valium (diazepam) has been proved by many clinical and empirical evaluations. Now, also objective criteria such as used in other areas of scientific research have demonstrated the effectiveness of Valium (diazepam) in reducing certain somatic responses to acute stress.

Devised as a research tool in psychosomatic medicine, this interesting method records respiratory excursions, galvanic skin resistance, cardiac activity and finger pulse volume as physical responses to stress. These autonomic nervous system responses to a standardized stressor—a film dealing with life-threatening incidents—are continuously monitored on the polygraph.

This gives a graphic representation of changes which the body may undergo in reacting to stress. The application of modern statistical analysis to these graphs provides a yardstick by which the calming effect of Valium (diazepam) can be measured quantitatively.

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Infants, patients with a history of convulsive disorders, glaucoma or known hypersensitivity to drug.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly or debilitated patients (not more than 1 mg, one or two times daily initially) to preclude ataxia or oversedation, increasing gradually as needed or tolerated. As is true of all CNS-acting drugs, until correct maintenance dosage is established, advise patients against possibly hazardous procedures requiring complete mental alertness or physical coordination. Driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. If such combination therapy is used, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, barbiturates, MAO inhibitors and other antidepressants. Advise patients against simultaneous ingestion of alcohol or other CNS depressants. Safe use in pregnancy not established. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances, acute hyperexcited states, hallucinations); changes in EEG patterns during and after drug treatment. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms (convulsions, tremor, abdominal and muscle cramps, vomiting, sweating) similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Dosage—*Adults:* Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. *Geriatric patients:* 1 or 2 mg/day initially, increase gradually as needed and tolerated. (See *Precautions.*)

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 and 500.

VALIUM® (diazepam) Roche®

useful for somatic symptoms of psychic tension

Dear Doctor:

Wouldn't you like your patients to learn more about the contributions made by the world of medicine to their welfare? So that they can better appreciate the efforts of the health team to keep them in good health?

To tell the stories of medical and pharmaceutical advances to people throughout the country, the Pharmaceutical Manufacturers Association is sponsoring a unique "magazine within a magazine." It is called *Medicines and your family's health* and the first issue appears in the November *Reader's Digest.*

We would like to send you 50 free reprints of *Medicines and your family's health* for use in your reception room. Your patients will find the articles in this issue factual, educational and of immediate personal interest.

Just fill out the coupon below and send it to us.

and

Letter® is micronized to provide maximum opportunity for full absorption and clinical response.

In addition Letter® is distinctively color coded with an identifying number stamped on each tablet to provide accurate dosage control.

Indications: Hypothyroid conditions. **Contraindications:** Thyrotoxicosis, acute myocardial infarctions unless associated with hypothyroidism. In hypothyroidism with hypoadrenalism coadministration of corticoids with LETTER® is recommended. **Precautions and Side Effects:** Excessive dosage may result in diarrhea, cramps, palpitation, nervousness, rapid pulse, sweating. If symptoms appear, discontinue medication for several days, then reinstitute at a lower level. Since myxedema patients with heart disease may suffer seriously from abrupt increases in dosage, caution should be exercised in adjusting dosage. **Dosage:** Generally, the initial adult dosage is 0.1 mg. daily. This may be increased in small increments every one to three weeks until proper metabolic balance is achieved. **Available:** Bottles of 100 tablets, in six potencies: 0.025 mg. (violet), 0.05 mg. (peach), 0.1 mg. (pink), 0.2 mg. (green), 0.3 mg. (yellow), and 0.5 mg. (white).

Book Reviews

Books are a guide in youth, and an entertainment for age. They support us under solitude, and keep us from becoming a burden to ourselves. They help us to forget the crossness of men and things, compose our cares and our passions, and lay our disappointments asleep. When we are weary of the living, we may repair to the dead, who have nothing of peevishness, pride, or design in their conversation.—Jeremy Collier

ATLAS OF VASCULAR SURGERY—Hershey and Calman. Second Edition, Published February 1967. C. V. Mosby Company, St. Louis.

This Atlas of Vascular Surgery is a very fine survey of the subject. It contains 307 pages of text with a useful 10-page index. The illustrations are excellent drawings that are easily understood.

Short and clearly descriptive text material is sufficiently complete to describe the various procedures. This Second and Revised Edition is up to date in the modern advancements of this rapidly changing field of surgery.

Chapters include Methods of Diagnosis, Aneurysm Disease, Occlusive Disease, Embolic Problems and Vascular Injuries.

Special areas involve descriptions of Superior Mesenteric Artery Problems, Renal Vascular Hypertension, Cerebral Occlusive Disorders, and Portal Hypertension. The value and methods of sympathectomy are related. Venous problems are outlined, including acute thrombosis and chronic venous disease.

Finally, another portion covers various amputations as related to the vascular problems.

The reviewer has found this Atlas to be most instructive. He can recommend this book as a useful reference source for the student, the resident, and the practicing surgeon.

J. H. Strickler, M.D.
Minneapolis, Minnesota

HANDBOOK OF ORTHOPEDIC SURGERY—Shands & Raney. C. V. Mosby Co., St. Louis, Publisher. Pages: 572. Illustrations: 269. Price: $12.00.

A handbook on orthopedic surgery obviously cannot cover in detail the entire scope of all the orthopedic problems, though it can give valuable information to the physician, whether in general practice, or in one of the specialties, who wishes to use it for reference material.

On this basis Shands and Raney have prepared a brief but comprehensive review of a great variety of orthopedic problems that can be encountered in a large general practice.

It is interesting to observe that the cervical root syndrome is accorded its relative significance and is not over-emphasized by the use of the jury-appealing term of whiplash.

The bibliography is interestingly arranged in a manner in which a curious investigator can obtain ready reference to a variety of items that might interest him. The book is well bound.

Carl O. Rice, M.D.
Minneapolis, Minnesota

ATLAS OF INTESTINAL STOMAS — Turnbull & Weakley. Publisher: C. V. Mosby Company. Price: $21.50.

This monograph on intestinal stomas has been beautifully prepared with numerous illustrations depicting the details of technique.

The intestinal stomas are designed principally in the operative treatment of ulcerative colitis and carcinoma of the colon, where it is necessary to make a permanent or a temporary deviating stoma.

To the surgeon who does this type of operation this monograph should be available, as it details a considerable number of procedures that have been found to be of value in the unusual circumstance.

Carl O. Rice, M.D.
Minneapolis, Minnesota

FOOT DISORDERS — MEDICAL AND SURGICAL MANAGEMENT — Nicholas J. Giannestras, M.D. Fleansebiger 1967. Price: $22.00.

In compiling a book with regard to foot disorders the author has commandeered the talents of a dozen outstanding men who have had interest in the various phases of foot disorders.

As specialties and sub-specialties develop, it is readily understandable that foot disorders could become one of the important sub-specialties of orthopedic surgery. In addition to orthopedic problems, there are also many medical problems as indicated in the chapter dealing with rheumatoid foot and neurologic diseases of the feet, gout and allied disorders. This book is well written, well edited and advantageously illustrated.

Carl O. Rice, M.D.
Minneapolis, Minnesota

"Good girl! You're down seven pounds."

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain.* When a new dietary pattern must be established, consider the adjunctive use of BAMADEX SEQUELS. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, BAMADEX SEQUELS controls appetite throughout the day, usually with a single capsule daily.

Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.
Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.
Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

(one tablet daily)

Regroton®

chlorthalidone 50 mg., reserpine 0.25 mg.

Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Regroton should be used in pregnant patients or in women of childbearing potential only when, in the judgment of a physician, its use is deemed essential to the welfare of the patients; adverse reactions (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.
Precautions: Antihypertensive therapy with Regroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue Regroton therapy two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, Regroton should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000. Classified Advertisements

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

PHYSICIAN NEEDED to serve as Chief Medical Director for State Prison at Stillwater. 50-bed hospital, laboratory technician, registered nurses. Salary ranges from $13,344 to $18,972 per year. Full time, permanent position under Minnesota State Civil Service. Contact: L. D. Jones, Minnesota State Prison, Box 55, Stillwater or call 439-1910, Ext. 320.

INTERNIST WANTED: Central Wisconsin city of 35,000 needs internist badly. Solo practice, association with small group or large clinic available. Contact G. H. Brister, M.D., Medical Arts Bldg., Wausau, Wisc.

SENIOR PARTNER retiring and wish another physician to join busy general practice. L. T. Winninger, M.D., 601 Baltimore St., Waterloo, Iowa 50702.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

WANTED: General practitioner, to join two G.P.'s well established in north central Minnesota community, 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital, all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. WRITE MINNESOTA MEDICINE—381; 375 Jackson, St. Paul, 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

WANTED: INTERNIST to enlarge busy internal medicine department in highly successful nine man specialty group. All are board certified. Well equipped lab and x-ray—new 120-bed hospital. Pleasant community of 15,000 plus on Mississippi River. Good recreational facilities, not far from Twin Cities. Salary one year then partnership. Write: George E. Jackish, M.D.—Interstate Clinic, Red Wing, Minnesota or call 507 388-3503.

MORGAN, MINNESOTA, Wants a General Practitioner. Opportunity to take over a well established practice. Physician recently retired after practicing here for 33 years. Progressive community in the best rural area of Southern Minnesota. New medical clinic building just completed. Call or write M. L. Kuhn, Morgan, Minnesota. Tel. Morgan #73 or #99.

GENERAL PRACTICE associate wanted for young three man group in populous growing area located 30 minutes south of the Twin Cities. Spacious three year old clinic with new accredited hospital and nursing home in same town. Salary and terms open. Contact River's Edge Medical Clinic, Farmington, Minnesota Telephone 463-7181.

PHYSICIAN WANTED: G.P. with additional surgical and OB experience—desired to associate with two G.P.'s with similar experience in large, well established practice in Central Minnesota. Hospital accredited, 300 bed, open staff, complete services. Salary leading to partnership. Adequate housing in area. Send background information, professional and personal to: MINNESOTA MEDICINE-283, 375 Jackson, St. Paul 55101.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

WANTED: Ophthalmologist to fill vacancy with well established eight man group. Beautiful award winning clinic just blocks from new 120 bed hospital. Picturesque community of 15,000 located on the Mississippi River with good recreational facilities, schools and churches. An excellent opportunity in a growing environment. Salary one year, then partnership. Write Harry Williams, M.D., Medical Block Clinic, Red Wing, Minnesota, or call 507, 388-4751.

GENERALIST AS MEMBER of Medical Staff of progressive State Hospital in Michigan's Vacationland. Hospital has 3-year accreditation, JCAH and 3-year residency accreditation by A.P.A. Salary $16,000 to $19,800. Excellent fringe benefits. Civil Service Security when qualified. Apply L. B. Young, M.D. Director of Medical Services, Traverse City State Hospital, Traverse City, Michigan 49684.

b.i.d.

The sensible schedule that covers the patient day and night

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, then you know why b.i.d. DECLOMYCIN is considered to be a sensible dosage schedule.

The maintenance dosage of DECLOMYCIN can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

The b.i.d. dosage of DECLOMYCIN gives you the comfortable assurance that the patient is well-covered, *day and night.*

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective; because of high serum binding and slow renal clearance. And if there's a broader susceptibility pattern of organisms, we've yet to see it.

There is no need to give higher daily dosage than 300 mg b.i.d., except in venereal diseases and Eaton Agent pneumonia.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Lederle

Prescribing information on next page.

b.i.d. The sensible schedule that covers the patient day and night

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occure. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes. A rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth— dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm. given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.

Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg. of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg. every 6 hours for a minimum of 4 doses or 300 mg. every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg. every 6 hours or 300 mg. every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg. in 3 divided doses for six days.

Cystic Fibrosis Detection Clinic Program in Minnesota*

WARREN J. WARWICK, M.D.**
JoANN KOROSHEC, R.N.**
Minneapolis, Minnesota

In 1965 we began planning a large scale sweat test screening program for cystic fibrosis in school children. The decision to do this program was based on four observations: (1) cystic fibrosis is estimated to occur in one of every one to two thousand newborn infants;[1] (2) nation-wide statistics indicate that one third of the deaths from cystic fibrosis occur by one year of age and one half by four years;[2] (3) the mortality rate for children with cystic fibrosis receiving prophylactic pulmonary cleansing therapy may be less than one seventh that of the national average;[3] (4) our attempts to find children with cystic fibrosis in Minnesota indicated that four out of five children born with the disease (assuming a newborn incidence of one in 1000) may not have been diagnosed.[4] Our purpose was to find the prevalence of undiagnosed children in order to check our estimates of the incidence and mortality and to give any undiagnosed children found the benefits of improved methods of treatment.[5] We selected the heat stimulus-chloride ion electrode sweat test for this survey because it is accurate, fast, and inexpensive when compared with the usual sweat tests.[6]

Testing Plan

Community Selection

Twenty-six cities and towns throughout Minnesota were included in this screening program. Because of the expenses involved, financial support was a major factor in community selection. The program was sponsored by the Minnesota Chapter of the National Cystic Fibrosis Research Foundation with financial and direct assistance from the Minnesota Mrs. Jaycees. Clinics were scheduled in selected

*This research project was supported by a Cystic Fibrosis Care Research and Teaching Center grant from the National Cystic Fibrosis Research Foundation and by the Minnesota Cystic Fibrosis Chapter and the Minnesota Mrs. Jaycees.
**Department of Pediatrics, University of Minnesota Medical School.

communities throughout the State of Minnesota in which the local Mrs. Jaycees' organization was able to provide financial assistance and volunteers for the project.

Organization of the Testing Program

The Minnesota Chapter of the National Cystic Fibrosis Research Foundation and the Minnesota Mrs. Jaycees obtained the cooperation of physicians and school officials in each of the 26 selected communities. The local news media were used whenever possible to provide lay education concerning cystic fibrosis and the "Cystic Fibrosis Detection Clinics."

The Cystic Fibrosis Care, Research, and Teaching Center at the University of Minnesota provided two technicians and the necessary equipment.

Form letters containing permission slips were distributed to children in kindergarten and grades one through four to be sent home to parents several days prior to the scheduled test day or days.

The Sweat Test

Whenever possible the screening tests were conducted in large, well ventilated rooms, usually gymnasiums, in local schools. Two sturdy tables were set up parallel to each other, about four feet apart at one end of the room and near electrical outlets.

After the equipment was set up and standardized[6] and the eight to ten volunteers were instructed in their jobs, the children were filed into the room by their teachers. The classes came at staggered times so that a continuous line was maintained. Each child held his own registration-parental permission slip.

At the first station each child to be tested had his anterior forearm washed with distilled water and dried with gauze. The prepared area was covered with a $4 \times 4''$ square of parafilm, and a heated aluminum cylinder (temperature of 48° C.) was placed on top of the parafilm to stimulate sweating. As soon as this was accomplished, the time was recorded on the child's registration slip so that an exact stimulus period of five minutes could be determined. The registration slip was then returned to the child.

As soon as the child's five-minute period was up, the technician's assistant placed the child's arm convenient to the technician and equipment and removed the heat stimulus and parafilm. At the same instant the chloride ion electrode was placed on the sweat on the forearm, and the meter reading was obtained and recorded on the child's registration slip.

This coordinated procedure permitted about 200 children to be tested each hour. Preschoolers required additional time and attention.

Children with sweat chloride test values of less than 30 mEq/L were judged to be normal and were discharged from the detection clinic. Children with a sweat chloride test value of over 30 mEq/L were judged suspects and were retested. If one or more test results were greater than 40 mEq/L the child was selected for retesting with pilocarpine iontophoresis.

Results

Between February and May of 1966, the screening sweat test program for cystic fibrosis was conducted in 26 cities and towns in Minnesota. The communities participating and the number of children tested in each are listed in Table 1.

TABLE 1

5-25-66	Granite Falls	514
Totals	26 Communities	20,071 Children

List of cities in which C.F. Detection Clinics were held with dates of testing and number of children tested.

Participation varied from community to community. In one school system all the children in the selected grades received permission from their parents to have the sweat test. In another school only half the children received permission. Nevertheless, on the average almost 95 percent of the children in school received parental permission to be tested. Class attendance varied from grade to grade and school to school from 90 to 100 percent with an estimated 95 percent attendance. Therefore, between 90 and 95 percent of the children whom we planned to test were tested.

TABLE 2

7-8	23	14
8-9	16	10
9-10	5	1
10-11	5	0
11+	1	0

Age and Sex

Equal numbers of boys and girls were tested. The age distribution by sex was the same as that of the total group shown in Table 2.

On the initial sweat test nearly 1,500 children (seven percent of the total tested) had sweat chloride values greater than 30 mEq/L. On retesting in the clinic 57 (¼ of one percent) were found to have persistently high sweat chloride values. The age distribution of children with high sweat tests was comparable to that of the whole group but there were 2½ times as many boys as girls with high sweat chlorides. Thirty-six of the high sweat chloride values occurred in two cities. These children were retested later in the spring with the pilocarpine iontophoresis technique.[7] On this third testing only two were found to have high values. These children and their families were studied in detail.

Increased Sweat Chloride

All of the members of family H (Figure 1) are in good health. The increased sweat chloride in R.H. detected in the Cystic Fibrosis Detection Clinic was confirmed by pilocarpine iontophoresis technique.[7] However, when R.H. was encouraged to use less salt on his food his sweat test values dropped into the definitely normal range. Final diagnosis was excessive salt intake in a normal child.

All members of family J (Figure 2) are in good health. The increased concentration of salt in the sweat found by the Cystic Fibrosis Detection Clinic was confirmed by the pilocarpine technique. All the tests done on the three oldest children including the suspected one have been in the high five percent of sweat chloride values for our laboratory. One child had several tests intermediate between normal and cystic fibrosis, but the latest ones are in the

high normal range. Our tentative diagnosis is normal child with excessive salt intake or familial tendency to salt loss in the sweat.

Fluctuation in Line Voltage

The three children living in these cities who were known to have cystic fibrosis were tested as positive controls. When one was missed by the testing team a review of the technique and an investigation of the equipment were made. Thus we discovered that under certain previously unknown circumstances, fluctuations of line voltage at the time of the sweat test could cause spuriously high values in some normal children or low values in some children with cystic fibrosis. As the unsuspected difficulty was not discovered and corrected until near the end of the testing program, the possible prior occurrence of temporary dysfunction of the meter due to line voltage changes and the coincident testing of a child with cystic fibrosis could not be known.

In an effort to discover this as a possibility we wrote to all the doctors whose patients participated in the testing program to ask: Have you discovered any new patients with cystic fibrosis in the year since the sweat test program in your city? If yes, did the patient have a sweat test in the school cystic fibrosis sweat test program? A letter was sent to 162 physicians, of whom 139 or 85.8 percent answered. Three new cases of cystic fibrosis were found during the year: one child was born several months after the testing program; the second was about five years old and thus in the group of untested children. This patient has been lost to follow-up by the reporting physician. The third was a five-year-old sibling of a child with cystic fibrosis, whose parents decided not to bring him to the school in which the detection clinic was held. None of the three had been tested in the program.

Altogether these 139 physicians reported caring for 109 patients with cystic fibrosis in prior years. Since about 106,000 infants in these 26 community areas were born during the past 20 years, we derive a crude incidence estimate of 109 cystic fibrosis children per 106,000 newborn infants or one child with cystic fibrosis in 970 newborn infants.

Analysis

Assuming an incidence of one case in 1000 newborn infants, 20 children were born into the group of children tested. Since the cumulative mortality from cystic fibrosis in patients not receiving pulmonary therapy is 70 percent by age seven we estimate that six should have been alive in these communities and detectable in the group. Three known patients resided in the towns listed and were in the grades tested. If these assumptions are correct and the test was effective, we should have found three others. But we found only two suspects, both of whom were found to be normal.

The difference between the finding of no new patients in the sample tested and the expected three could be the result of:

1) Chance
2) Failure to test all the children, the patient with cystic fibrosis being in the non-tested group
3) Error in estimate of mortality
4) Error in estimate of incidence
5) Failure of the test

Chance?

If the true prevalence of *undiagnosed* cystic fibrosis in a mixed group of children, average age seven (see Table 2), in Minnesota is three cases per 20,000 we would expect to find no cases once every five times we tested a sample of 20,000. Thus, our results are a probable and expected chance variation and the assumptions are not disproven.

Failure to Test All the Children?

Since about five percent of the children scheduled to be tested were absent on the day or days of the testing program and since about five percent of the parents refused to have their children tested, the tested cohort represents about 90+ percent of the actual cohort. Although this is a very large proportion, it may still be a biased sample.

Failure to have all the children present when the testing was done resulted in failure to detect two cases. To get cooperation from all the parents for this type of project is an almost insurmountable obstacle of potential significance to any large-scale testing program. That the small fraction missed in this study appears

to have affected the results tends to confirm this postulation.

Refusal of testing would have had no effect on the test if refusal were only a randomly-occurring bias against any testing program, but we do not know whether or not some parents refused to have a child tested because they suspected that the child might have the disease. That a group of absentees may include children with cystic fibrosis is to be expected, for children with cystic fibrosis who do not receive prophylactic pulmonary therapy are ill more frequently and miss more school than normal children. Any future population screening programs will have to include a technique for testing all children in the population, since even a random, unbiased sample of the healthy children would miss the child with cystic fibrosis who was sick on the day of testing.

Error in the Estimate of Mortality?

A life expectancy table for children with cystic fibrosis in Minnesota shows the expected mortality by age one year to be 36 percent, by seven years to be 70 percent.[2] A higher mortality rate is indeed possible; Dr. Norman's calculations suggest that the survival to age seven could be less than 20 percent[8]; but without more complete data a higher mortality cannot be proven. Yet the possibility emphasizes the need for perfection of a test for cystic fibrosis in the newborn period.[1]

Error in the Estimate of the Incidence?

Failure to find the expected number of cases of cystic fibrosis could be explained by too high an estimate of the number born. A corrected estimate based on the three known cases plus the two later discovered and our mortality estimate would be one in 1200 newborns. The corrected estimate is within the acceptable range of one in 1000 to one in 2000 newborn infants and not significantly different from our original assumption. Final certification or further correction of our estimate awaits the widespread utilization of the chloride ion electrode sweat test in the newborn nursery.[1,9]

Failure of the Test?

In over three years' use in our laboratories, the chloride ion electrode sweat test correctly identified every new case of cystic fibrosis and every normal child. Every chloride ion electrode test in the laboratory has been followed with the pilocarpine iontophoresis sweat test for confirmation. Since the testing conditions in mass testing situations were less well controlled than those in the laboratory, some decrease in accuracy was predicted. Most of the anticipated problems developed and were all solved during the months of testing. The malfunction of the meter caused by turning on fluorescent lights or by large fluctuations in line voltage was unexpected and was discovered only near the end of the testing program. All in all, it is impossible to disprove the possibility that such test failure occurred and led to failure to detect one or more children with cystic fibrosis. However, as great precautions were taken to have a "fail-safe" test and in view of the proven accuracy of the test in the laboratory this does not seem likely. Moreover, the failure to find even one case among the tested patients during the year after the program in which two nontested children were found to have cystic fibrosis provides strong, although negative, support for the reliability of the test.

Discussion

Although the ease, speed, and accuracy of this test indicates that it is the best available for population screening, the few children expected to be found alive and undiagnosed by school age and the rather large investment of time, effort, and money required suggest that routine screening of school-age children is not to be recommended. Nevertheless, the technique is applicable for large-scale screening programs designed to answer specific questions or as a preliminary survey prior to setting up routine nursery testing. The lessons learned and the improvement in equipment and technique which grew out of the survey establish this technique as the best available way to do accurate population surveys for cystic fibrosis. That no children with cystic fibrosis were found in the testing program and only three were found by physicians in these cities during the following year supports our predictions suggesting that the early mortality from cystic fibrosis is as high as—perhaps higher—than our estimates.

Conclusions

Two conclusions are apparent: First, the screening should best be done at an age when the greatest likelihood exists that the child born with cystic fibrosis is still alive; thus, newborn screening is most to be desired. After that in decreasing order would be older infants, pre-school, and grade-school children. Testing junior or high school students would appear to be of little value since most children with cystic fibrosis not receiving pulmonary therapy would be expected to be dead or diagnosed by age 10.

Second, that the costs of the present testing program are low enough to warrant recommendation for trials of newborn and infant screening to establish the validity of and techniques for newborn nursery screening on a routine basis. We believe that further large screening programs of pre-school and grade-school children may be of value in special circumstances but that it would be desirable to develop a less expensive technique for use in these older children.

When a newborn nursery sweat test for cystic fibrosis has proved to be practicable, we will be able to start our present treatment program at a time when great gains in survival are to be expected. Then we will do more research to simplify our treatment procedures so that they can be applied successfully by a large proportion of families and can be made more useful to other children with bronchitis, asthma, bronchiectasis, or pneumonia. Since it has been shown that most of the pulmonary treatments developed for children with cystic fibrosis are of great value in the treatment of the other lung disorders in childhood, the earlier diagnosis of cystic fibrosis combined with controlled study of treatments may be expected to improve the health and perhaps save the lives of children with other lung diseases.

UNUSUAL OPPORTUNITY. Internist or GP interested in internal medicine. Small multispecialty group midwest city of 8,000, population area 50,000. Accredited hospital. Modern Clinic. Salary open, with early partnership. Write: Minnesota Medicine—390, 375 Jackson, St. Paul, Minnesota 55101.

Kevin Is a Hippie

(Continued from Page 61)

finds us and our loved ones well and happy, and the entire Hoppworth Family joins in expressing the most heartfelt wish that every good thing may be yours throughout the coming year."

A final embellishment that will go far towards the construction of a really first-rate Christmas Letter is the enclosed photograph. This may be a snapshot of a new yacht or western ranch, but nothing can compare in effectiveness to the family group photograph. The group must include all members and it is imperative that everyone be smiling. Remember that a heavy set of dental braces is an indication of family commitment to better living and will go a long way to presenting an image of a Family Who Cares. If at all possible the family pet or pets should be included. I usually borrow a neighbor's cat because I have noticed that poets and other intellectuals seem to show a preference for cats, but a dog or dogs will do as well; if a fine saddle horse can be seen grazing in the background, so much the better.

There you have the barest rudiments of a Christmas Letter. The choice of color of paper and ink I leave to you. It is my hope that this little essay may be valuable, even inspirational to Christmas Letter authors of all degree of proficiency. I foresee the day when the mailmen of America will bend low beneath a burden of truly beautiful Christmas Letters from almost every family in the nation.

E. A. Doherty, M.D., W.

Psychology has its Gresham's Law; its bad money drives out the good. Most people tend to perform the actions that require least effort, to think the thoughts that are easiest, to feel the emotions that are most vulgarly commonplace, to give the rein to desires that are most nearly animal.—Aldous Huxley

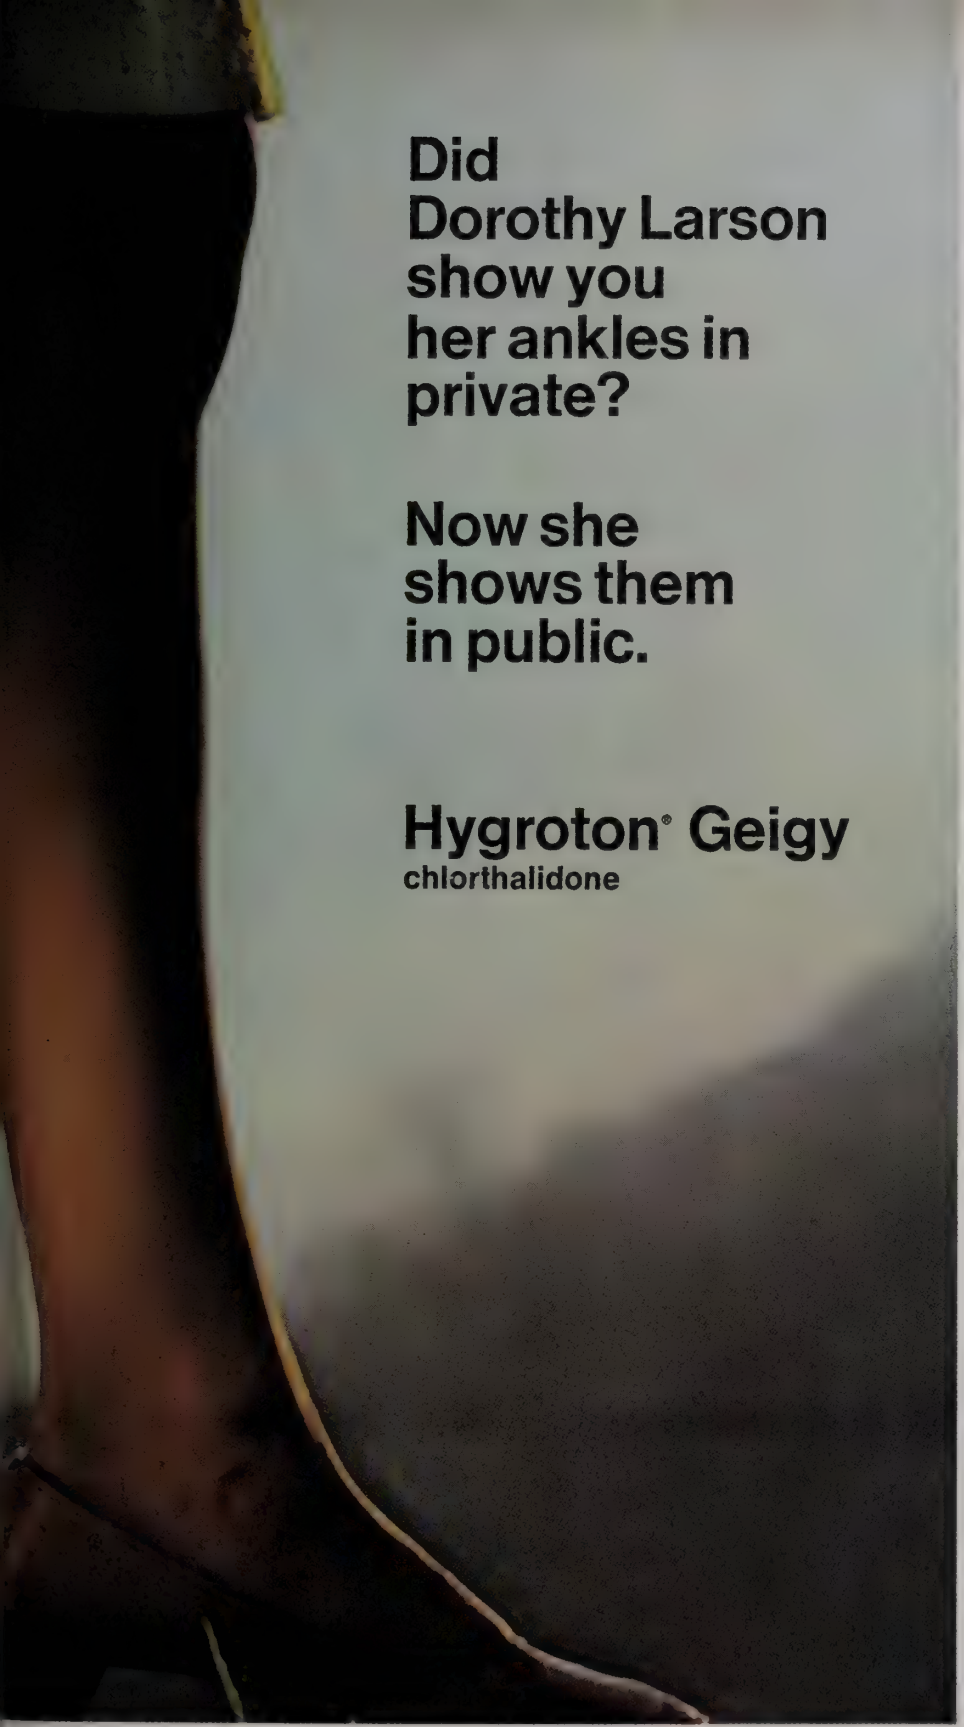
EMPIRIN'® COMPOUND with CODEINE PHOSPHATE gr. 1/2 No. 3



Each tablet contains: Codeine Phosphate gr. ½ (Warning—May be habit forming), Phenacetin gr. 2½, Aspirin gr. 3½, Caffeine gr. ½.

■ Despite introduction of synthetic substitutes, efficacy of 'Empirin' Compound with Codeine remains unchallenged.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

Indications: Hypertension and many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Use with caution in pregnant patients, since the drug may cross the placental barrier and adverse reactions which may occur in the adult (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.
Precautions: Antihypertensive therapy with Hygroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents or other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Barbiturates, narcotics or alcohol may potentiate hypotension. Be
cause of the possibility of prog
sion of renal damage, periodic
determination of the BUN is in
cated. Discontinue if the BUN
or liver dysfunction is aggrava

Did Dorothy Larson show you her ankles in private?

Now she shows them in public.

Hygroton® Geigy
chlorthalidone

Your office examination confirmed Mrs. Larson's ankle edema.

You prescribed Hygroton—to get rid of the edema.

And you found that Hygroton is not only effective; it frequently costs less than other equivalent therapy.

A nice way to treat the Mrs. Larsons in your practice.

Hygroton therapy may mean troublesome side effects for some patients. A summary of the prescribing information is shown below.

ient does not have marked oli-
ia.
e special care in cirrhosis or
ere ischemic heart disease and
atients receiving corticoste-
ds, ACTH, or digitalis. Salt re-
ction is not recommended.
verse Reactions: Nausea, gastric
ation, vomiting, anorexia, con-
ation and cramping, dizziness,
akness, restlessness, hypergly-
nia, hyperuricemia, headache,
scle cramps, orthostatic hypo-tension, aplastic anemia, leuko-penia, thrombocytopenia, agranu-locytosis, impotence, dysuria, transient myopia, skin rashes, urti-caria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions re-ported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.
Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.
Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

Minnesota Medicine at a Glance

Prophylaxis in Oral Surgery—Waite, et al. Page 21

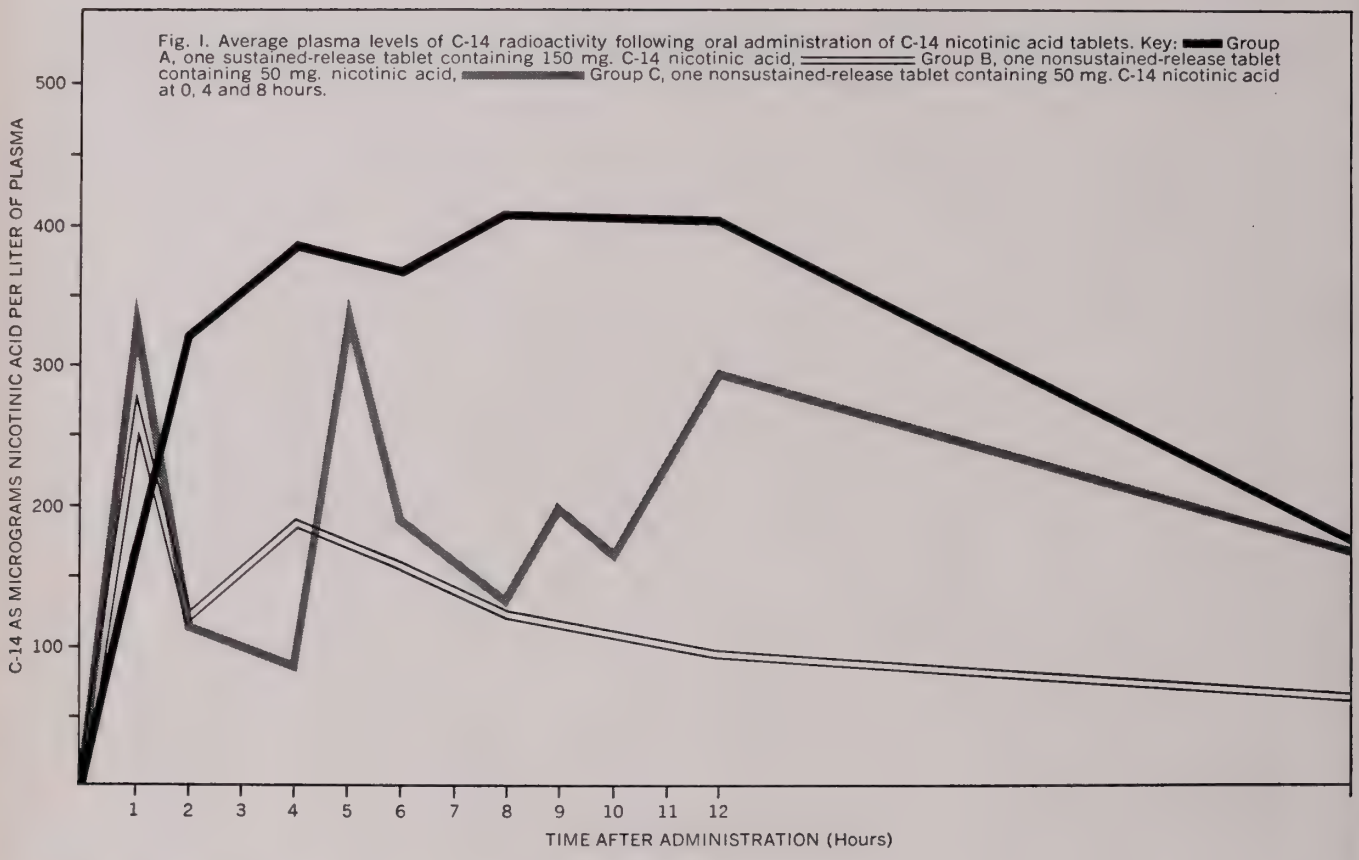
This article deals with the prophylactic administration of antibiotics in the course of oral surgery. The studies indicate that the use of an antibiotic does diminish the bacterial content of the blood which was observed after oral surgery.

Chronic Obstructive Airway Disease—Dines and Fowler Page 33

Two simple office or bedside procedures can effectively screen most ventilatory problems. Inability to blow out a paper match at 6 inches correlates well with a one-second vital capacity of 1500 ml. or less, and a maximum breathing capacity of 40 liters per minute. Also described is the bellows-timed vital capacity. Both tests are correlated with pulmonary function studies.

D. Pneumoniae—Shope and Quie Page 37

This article is about a pediatric patient with recurrent staphylococcal infections and with fatal pneumococcal pneumonia. The pneumococci isolated from the blood showed an increased resistance to oxacillin. The need for sensitivity studies is stressed.



Traumatic Rupture of the Testicle—Wedge and Blackard Page 73

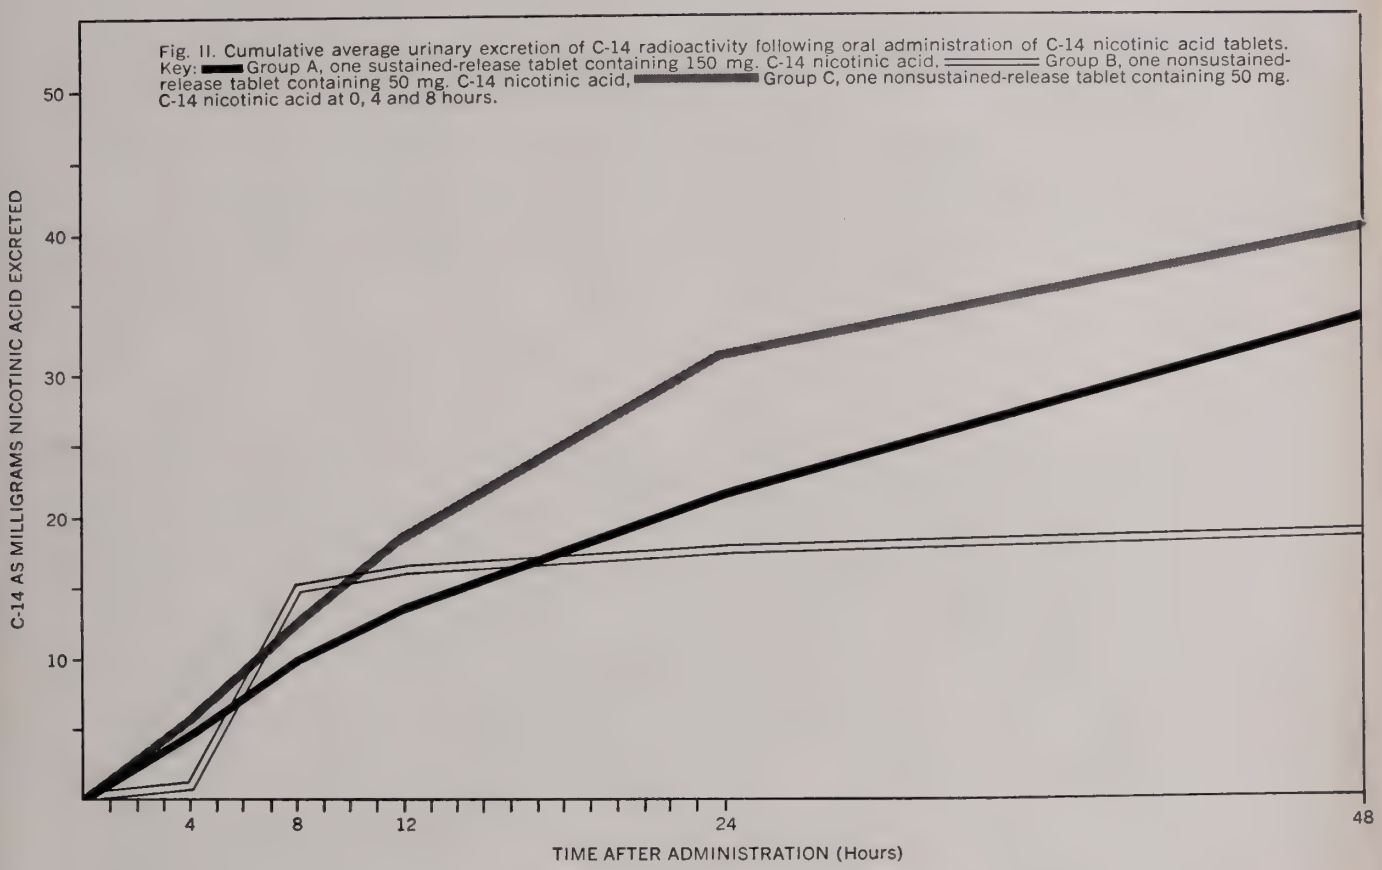
Traumatic rupture of the testicle should be suspected in every scrotal injury resulting in swelling and induration of the scrotal contents. Prompt surgical decompression of the hematoma and debridement of devitalized tissue will likely result in a greater salvage of functional testicular tissue.

Cystic Fibrosis—Warwick and Koroshec Page 153

Over 20,000 children were tested for cystic fibrosis in a school sweat test screening conducted in 1966. Although no new cases were discovered in the tested group, three new cases were discovered among non-tested children in the year after the Cystic Fibrosis Detection Clinics were held. These findings support the prior assumptions that one child is born with cystic fibrosis among each 1000 newborn infants and that over 70 percent of these children not receiving pulmonary therapy, die before age seven. These findings also suggest that now is the time to begin trials of newborn nursery screening for cystic fibrosis.

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by absent-minded patients)



Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

BSP® DISPOSABLE UNIT

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

(50 mg. per ml.)

BSP®

ROMSULPHALEIN®

N A COMPLETE,

STERILE,

DISPOSABLE,

& ECONOMICAL

PATIENT-UNIT.

BSP, one of the more valuable single laboratory procedures for determining hepatic function, is now packaged in a complete individual patient-unit.

Each BSP Disposable Unit contains a sterile syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of terminally sterilized Bromsulphalein solution.

This all-inclusive disposable put-up lessens the chance of cross-infection and saves time and labor— the most costly commodities.

DORSEY "FLU-GRAM"

DON'T BE LULLED BY RELATIVE LACK OF FLU LAST WINTER. THIS WINTER BE PREPARED: WHEN THE COMPLAINTS ARE COUGH AND CONGESTION, YOU CAN RELIEVE THESE SYMPTOMS WITH TUSSAGESIC TABLETS. ONE TIMED-RELEASE TABLET AT MORNING, MIDAFTERNOON AND BEDTIME BRINGS UP TO 24 HOURS' RELIEF FROM TROUBLESOME COUGH AND STUFFED AND RUNNY NOSE. TUSSAGESIC IS THE FAMOUS TRIAMINIC FORMULA, PLUS THREE OTHER PROVED CONSTITUENTS. MAKES PATIENTS MORE COMFORTABLE. FAST. ASK YOUR DORSEY REPRESENTATIVE FOR SUPPLY OF STARTER SAMPLES, OR IF FLU IS ALREADY EPIDEMIC, PHONE COLLECT. SEE BELOW.

each

Tussagesic®

timed-release tablet contains:

Triaminic® (phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	50 mg.
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. Side effects: Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. Precautions: The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to Minnesota Medicine, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in Minnesota Medicine. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

President's Letter

PERHAPS AT NO other time in the history of medicine have we been faced with so many profound changes within the Profession. These changes have involved medical education, patterns of practice, payment for medical care, and the delivery of medical services.

We have seen, in the last quarter of a century, the dwindling number of solo practitioners and the extensive development of group practices. We have become aware of the decreasing number of small-town physicians and the tendency of physicians to congregate in the larger communities. We have seen the decreasing number of privately endowed hospitals and the development of the hospital financial structure based on sound business principles. We have seen the emergence of prepayment medical care plans and more recently have witnessed the entrance of Federal Government into the field of medical care.

The information explosion which has deluged us with knowledge has merely whetted our thirst for more. It introduced us to specialization as a means of better cataloging this knowledge and as a useful tool for further research. The use of the same fragmentary approach to the delivery of medical care has met with recent public and professional rebuff as documented by the Millis and Willard reports.

We, in medicine, must learn to be responsive to the public demands. The public, our patients, are rapidly becoming much better medically educated and much more sophisticated in their attitudes toward medical care and these demands. In many cases it will be difficult to resolve conflicts between demands, needs, and feasibility.

To do this effectively and still maintain physician control of the Medical Profession will require that the quality of medical care available be of the highest caliber. To do this we will need a vast expansion in our Postgraduate Education Programs. The possibility of recertification examinations, such as the American Academy of General Practice is planning to initiate, with the proposed American Board of Family Practice, will undoubtedly be one means which may have to be applied to other segments of the Medical Profession.

More attention must be paid to the delivery of medical care. Included in these studies would be not only the development of more efficient ways to adequately take care of more patients per physician, but also the methods by which physician's services could be made available to certain areas which consistently have inadequate physician coverage.

We can no longer sit back and complacently contemplate the fine record of American Medicine. We must anticipate the public needs and learn to respond to public demands in a manner calculated to fulfill public requirements and improve overall medical care. This of course also implies that we physicians must organize ourselves well enough to more effectively cope with third-party intervention into medical care: not from a defensive stance, but with an aggressive forward-looking program which will leave no vacuums to be filled by socialistic Government Programs.

Lower Limb Amputations in Peripheral Vascular Disease*

Factors Influencing the Level

WILLIAM J. KANE, M.D., Ph.D.**
Minneapolis, Minnesota

THE PROBLEM of peripheral vascular disease necessitating amputation is a major health problem and is increasing. Sidney Fishman of N.Y.U. estimates that there are 400,000 amputees in the United States, and because of prolonged life spans there is an increasing incidence of amputations due to peripheral vascular disease.[1] In a recent survey by Glattly, 55 per cent of the persons presenting themselves for prosthesis† fitting were victims of disease, and it has been shown that only about half of the geriatric patients who have had major amputations present themselves for prostheses.[2,3] Accordingly, it can be safely maintained that over two thirds of the amputations performed in this country are due to peripheral vascular disease, considering that Glattly's classification included infection in his "disease" category and recognizing that amputations about the foot and toes do not usually require prostheses.*

The purpose of this paper is to discuss some of the factors which influence the level of amputation in patients with peripheral vascular disease.

Amputations in peripheral vascular disease are performed to remove infection, gangrene, and pain, and consequently to preserve health and life and to improve function. Function following an amputation is largely dependent upon the level of amputation and whether a prosthesis is used. The general principle of amputation surgery is to save as much limb as possible consistent with the control of the disease process; practical experience is required to apply this principle in specific situations. It is also necessary to consider briefly prosthetic-fitting criteria, for this problem is intimately connected with the level of amputation.

Contraindications to Prostheses

It is generally felt that certain factors represent absolute contraindications to limb-fit-

*See editorial page 209.

**Assistant Professor, University of Minnesota Medical School, Department of Surgery, Division of Orthopedic Surgery, Minneapolis, Minnesota.

†See Test Your Word Score Page 217.

ting and that, therefore, the usual necessity to preserve limb length is removed. These factors include:

1. Lack of motivation
2. Impending gangrene of the other leg
3. Serious cardiac condition—Class IV
4. Severe neurological disorders
5. Multiple major physical disabilities
6. Known inadequate life expectancy.

Relative contraindications include:

1. Senility
2. Inability to use upper extremities
3. Extreme obesity
4. Severe flexion deformities
5. Intercurrent disease[4,5]

A word of caution about these contraindications. It may be quite difficult to establish that a patient is truly lacking in motivation; the patient's dejection at the impending amputation may obscure his genuine desire to wear a prosthesis. In most instances, the geriatric patient should be approached in a positive manner regarding his potential for using an artificial limb. It must be recognized that many such patients will not function at a level considered adequate when compared to preamputation levels; nor should we anticipate that they will function at a level which is established for younger patients. Such levels of achievement are not required for successful rehabilitation of the geriatric patient.

The use of an artificial limb is an additional tax on the cardiac reserve and the peripheral vasculature. It requires at least 20 to 25 per cent more energy for a unilateral above-the-knee amputation to cover a given distance than it does to walk on two normal legs.[6] Therefore, one has to evaluate the cardiovascular system carefully to prevent this additional expenditure from bankrupting the geriatric physiology.

The goals of amputation surgery are to preserve life and maintain health by eliminating infection and necrosis, to improve function and eliminate pain, to obviate the need for further amputations and possibly to allow the use of prostheses. In serving these aims the surgeon faces the dilemma of deciding which is the optimal site for amputation. The hope of saving as much tissue as possible is tempered by the realization that the more proximal the amputation, the quicker the healing; and until recently it was fairly obvious that surgeons were more frequently solving the question by going to the higher amputation sites. Glattly, in his review of the amputee census, discusses a group of 4500 above-knee and below-knee amputations for disease. He states: "It may be that too many surgeons are overly concerned with the possibility that amputations at the below-knee level will later require re-amputation above the knee. This possibility is suggested by the fact that in this series there were only 12 instances in which below-knee amputations due to disease were re-amputated at a later date. This is an extremely low incidence, considering the number of below-knee amputations that are performed for vascular conditions. A clinical study may be needed that is designed to define better the criteria that bear upon the decision as to the level of amputation in cases of lower extremity vascular disease. The advantages of preserving the knee joint are obvious, especially in the older age group."[2]

Levels of Amputation

The selection of the appropriate level of amputation in the geriatric patient with vascular disease should be based entirely on the level of vascular sufficiency in the extremity. By vascular sufficiency is meant that healing of the tissues will follow surgery, and the only reliable guide to this is free bleeding at the time of the amputation. There are, of course, other indicators which are helpful, but they are only relative. These signs are skin temperature and color, absence of trophic changes, palpable pulses, rapid venous filling time and reactive hyperemia. Regression of local infection, a sharp line of demarcation, and the absence of rubor on dependency at the amputation site also portend a successful amputation.[5] Of the various mechanized tests available, probably oscillometry is the most easily used clinically.[7] X-rays of the pelvis and upper portion of the thigh also give information regarding the state of calcification in the arterial tree, and angiograms may indicate the feasibility of peripheral by-pass grafting with venous grafts.

Attention will first be directed to the prevention of amputations. Impending gangrene

may be substantially improved by venous grafts where there is a popliteal run-off. While this is a possibility in arteriosclerotic disease, it is usually unsuccessful in peripheral vascular disease complicated by diabetes, for in diabetes not only does the arteriosclerotic process occur, but there is the concomitant endothelial swelling and occlusion which prevents collateral circulation from developing. For the same reason, sympathectomy is believed to offer little to the diabetic.[8] Endarterectomy in the more proximal vessels also benefits some of the arteriosclerotics uncomplicated by diabetes. In a like manner, meticulous wound care with frequent baths in detergent followed by gentle drying, the avoidance of trauma, rest, treatment of the cardiovascular disease and cessation of smoking may avoid an amputation.

Local Toe Level

If local toe infections do not respond to conservative management, amputation of the toes should be considered under the following conditions:

1. Only one toe involved with a terminal ulcerative or gangrenous lesion that is well demarcated and stabilized after several weeks of rest.

2. Lesions at the level of the middle phalanges of the second, third, and fourth toes will not respond to toe amputation, since these toes should be amputated through the proximal phalanx.

3. Willingness on the part of the patient and surgeon to invest three to 10 weeks in preoperative preparation in the face of a 45-per cent failure rate.

Toe amputations are contraindicated if pulses distal to the femoral vessel are absent, and if uncontrollable rest pain and dependent rubor are present.[5,9,10]

It is wise to avoid a prolonged hospital stay in such situations, because most of these patients with diabetes will develop gangrene in the opposite limb or succumb to their cardiovascular disease, and morale can deteriorate rapidly in prolonged confinement.

Transmetatarsal Level

If the conditions for a solitary toe amputation are not met, the next level is the transmetatarsal, which offers many advantages over a below-knee amputation. It is a minimum handicap, requiring no prosthesis and causing little additional contralateral limb strain. Transmetatarsal amputations should be considered when:

1. Stabilized distal gangrene not involving the dorsal or plantar surfaces of the forefoot is present in a healable foot, with circulation sufficient to control gangrene with bed rest, antibiotics, and diabetic control.

2. There is no ischemic foot pain on rest, no dependent rubor, and a venous filling time of less than 25 seconds.

3. The entire lesion can be excised and primary suture obtained. A transmetatarsal amputation is not an alternative after failure of a toe amputation.[5,11,12]

Recent evidence offers much hope that transmetatarsals give very acceptable results. Usually, 10 per cent are early, complete failures, but this is a reasonably low figure and the amputation may persist as long as two years. In one series of diabetics, 46 per cent of the living patients had intact incisions at five years; it must be noted, however, that only 23 per cent of the patients were alive at that time.[5,12]

Peripheral vascular disease does not lend itself to Syme's or hindfoot amputation; hence they will not be discussed.[5]

Below-Knee Level

The next level is the below-knee amputation which apparently is worthy of more consideration than it has received in the past in the treatment of peripheral vascular disease. It is not without some justification that surgeons elect the higher level. In one series of 83 above-the-knee amputations, 75 were satisfactory while only 27 out of 81 below-the-knee amputations were satisfactory[13] Given proper guidelines, though, the knee joint can be saved. Record, Smith, Kelly and Janes have enumerated some of these guidelines.[5,13,14] The advantages of a below-the-knee amputation include an apparent lesser mortality; but this may be the result of a biased selection in which the more severe problems are subjected to above-the-knee amputation. Below-the-knee amputations have better function with less contralateral stress than above-the-knee amputations, and their prosthesis if useable is

lighter. Balance is easier, as is turning in bed with a below-the-knee amputation.

General agreement can be reached by saying that a patient may be offered a below-the-knee amputation if the following criteria are met:

1. There is some hope of rehabilitation.
2. There is good bleeding at the amputation site with contractile muscle at that level and good warm skin to the middle of the leg and, if possible, to below the lower third.
3. A femoral pulse is palpable.

A palpable popliteal pulse is desirable, but if it is not palpable there should be oscillometric excursions in the calf. Kelly and Janes state that an absent femoral pulse and a history of sudden arterial occlusion absolutely contraindicate a below-the-knee amputation.[14] A slow onset of the disease rather than a sudden occlusion allows for satisfactory below-the-knee amputations. Obviously, a functioning knee joint is necessary.

It appears that age also has an influence on the results of surgery. In Smith's series, all patients under 52 years of age had good below-the-knee stumps; he also states that a palpable popliteal pulse usually promises a satisfactory below-the-knee amputation; but even in the absence of a popliteal pulse, 20 per cent will have worthwhile below-the-knee amputations if there are oscillometric excursions in the calf.[13]

In Kelly and Janes' review of 131 below-the-knee amputations, there were 31 severe wound complications, half of which were in patients with sudden arterial occlusion. The mortality rate for below-the-knee amputations was 3 per cent.[14] Most authors agree that stumps may be shorter in peripheral vascular disease and advise stumps of around four inches.[13] Smith points out that if a below-the-knee stump is going to give trouble it usually will do so in less than a year. If it does, do not revise the below-the-knee, for Smith found 100 per cent failure in 17 below-the-knee revisions of earlier below-the-knee amputations. For similar reasons, do not leave a long below-the-knee stump, planning on a shortened revision later. Do the below-the-knee amputation at the four-to-five inch level as the first procedure.[13,14]

Above-Knee Level

The indications for above-the-knee amputation obviously include the inability to meet the criteria necessary for amputation at the lower level and some absolute indications requiring an above-the-knee amputation:

1. Patients who can tolerate only one procedure or who have a diseased knee joint should receive the above-the-knee amputation as well as patients with unsuccessful below-the-knee amputations.
2. Patients with gangrene of the middle third of the calf or with extensive gangrene of the distal third of the calf.
3. Sudden arterial occlusions with weak or absent femoral pulses should indicate an above-the-knee amputation, as do sudden arterial occlusions with coolness of skin above the middle of the leg, high venous filling times, severe ischemia detected by elevation-dependency tests, and only fair bleeding at the below-the-knee site. The mortality for above-the-knee amputation is approximately 10%.[14]

Discussion

As the geriatric population increases and longer life-spans are achieved, an increased incidence of amputation due to arteriosclerotic conditions is anticipated. Many surgeons adopt an overly conservative approach to amputations about the toes and foot; but in amputations about the knee are perhaps overly aggressive, amputating above the knee in certain instances where below-the-knee amputations would have an excellent chance for success. Points that deserve emphasis are that sudden femoral arterial occlusions, with the corresponding lack of an opportunity to prepare collateral circulation, are indications for above-the-knee amputations, and that failures of below-the-knee amputations cannot be salvaged except by above-the-knee amputations.

Summary

Amputations for peripheral vascular disease are increasing. The indications for, and advantages of, each of the four chief levels of amputation are presented and should offer the surgeon planning an amputation a guideline to the level to be selected.

Acute and Subacute Fibrinopenic Syndromes

A Synthesis of Current Concepts

ROBERT B. BREITENBUCHER, M.D.*
Minneapolis, Minnesota

ACUTE DEFIBRINATION always represents a serious diagnostic and therapeutic challenge to the physician and a serious threat to the patient's life. Its manifestations are not usually heralded by any warning signals, nor is there any history of previous hemostatic dysfunction in the afflicted patients. Fortunately, the clinically manifest form of the syndrome is rare, although apparently a subclinical form may be found more frequently if carefully looked for.[1] The syndrome usually occurs as an obstetrical complication, although it may also be seen as a surgical complication, particularly in pulmonary surgery. Nothing creates more alarm than bleeding which cannot be stopped. By the same token, confusion ensues unless well planned diagnostic and therapeutic procedures are immediately available and put to use.

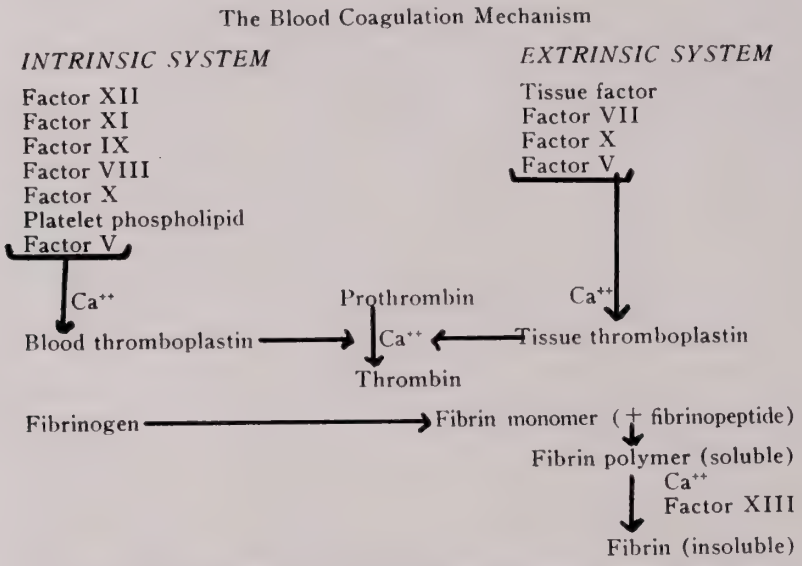
Review of Hemostatic Mechanism

The Vascular Wall

The first line of defense in hemostasis involves the integrity of the vascular wall. If a vessel is injured, the flow of blood to the vessel is reduced by constriction of afferent vessels. Contraction of the surrounding extravascular tissue produces some degree of compression which is helpful in stemming the flow of blood from the injured vessel.

Platelets pile up at the site and, if the injury is small enough, may patch the rent. Blood escaping through the rent forms a gelatinous coagulum which plugs the defect. Malfunction in any one will result in defective hemostasis.

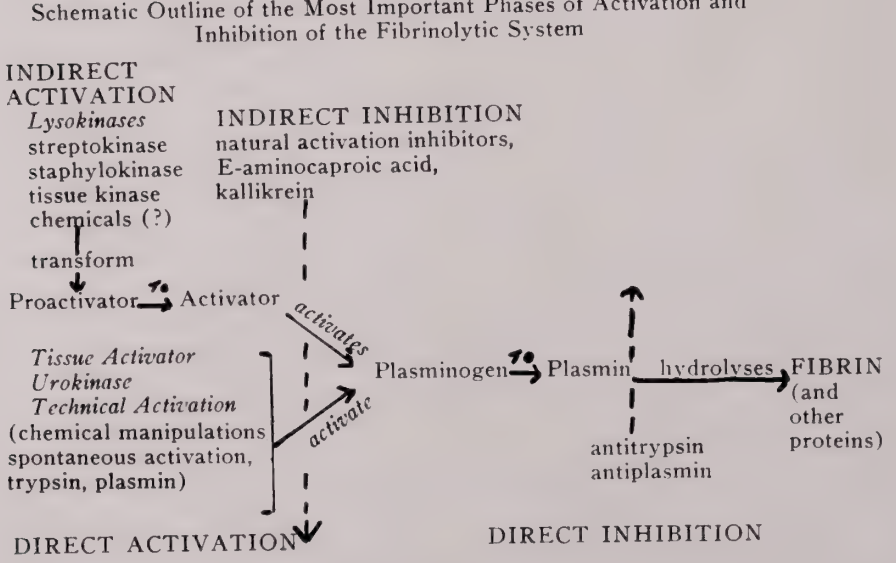
The process of formation of the coagulum is a complicated and confusing one. In recent years this confusion has been largely cleared by an International Committee on Blood Clotting Factors. Figure 1 is a simplified schematic representation of the various factors listed in the probable order of action which eventually leads to the formation of insoluble fibrin, the structural matrix of the coagulum.



Body functions are often subject to check

*Chief of Medical Service, St. Mary's Hospital.

and balance systems; coagulation is an excellent example. Opposing coagulation is the fibrinolytic system activated partly by coagulation itself.



Fibrinolysis

The teleological explanation of fibrinolysis is that it serves to prevent too extensive coagulation and to reopen coagulated channels which have been closed in response to the emergency induced by blood loss. Many other conditions may also activate the system.[2] Figure 2 shows a schematic representation of the essential mechanics of the fibrinolytic system

From R. M. Hardisty & G.I.C. Ingram: Bleeding Disorders, Blackwell Scientific Publications, Oxford, 1965

Figure 1

From Kurt N. von Kaulla, M.D.: Chemistry of Thrombolysis: Human Fibrinolytic Enzymes, Charles C. Thomas Publisher, 1963

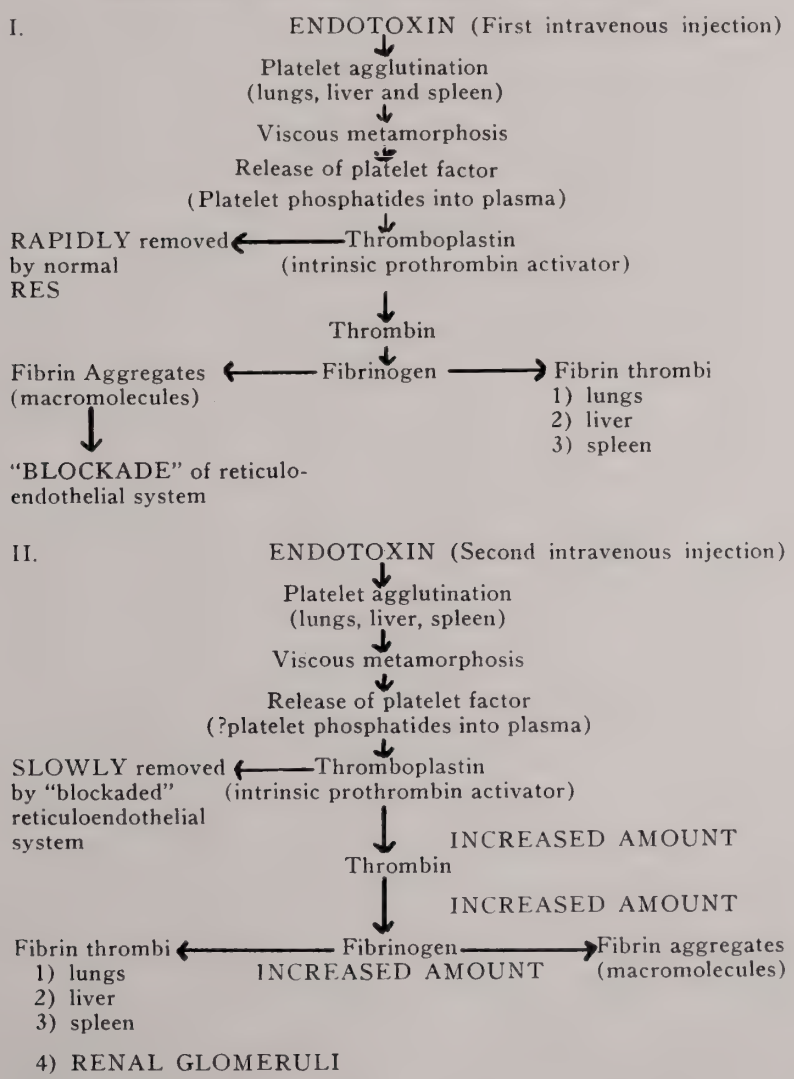


Figure 2

as it is recognized today.

Disseminated intravascular coagulation may result from activity of a variety of primary etiological factors, including hemolysis, tissue extracts, bacterial endotoxins, antigen-antibody complexes, proteolytic enzymes, particulate matter, anoxia, endothelial damage, fibrinolysin inhibitors, etc.[3]

Though the initiatory factors are diverse, the functional and pathological changes which follow are similar. Hypotension due to obstruction of blood flow through hepatic and pulmonary circulation by thrombi is almost always present. Changes in concentration of blood coagulation components used in the clotting process give results ranging from only transient platelet agglutination and thrombocytopenia in minor cases to severe depletion of fibrinogen, leukocytes, platelets, prothrombin, and factors VIII and IX. In the most severe cases a marked fibrinolytic activity appears which increases the depletion of factors I, II, V, VIII, IX. Depending upon the severity of derangement, hemorrhagic tendencies of varying degrees appear. When the clotting process is mild, platelet emboli may obstruct arterioles and capillaries only temporarily with no perma-

Mechanisms of the Classic Generalized Shwartzman Reaction

From Donald C. McKay: Disseminated Intravascular Coagulation, Hoeber Medical Division, Harper & Row Publishers, 1965

Figure 3

nent tissue damage. When the clotting process is severe, thrombotic obstruction of vessels leads to tissue necrosis of variable degree depending upon the extent of capil'ary clotting and whether or not large venous vessels become secondarily thrombosed. Lungs, brain, kidneys, adrenals, pancreas, gastrointestinal tract, and liver may be involved. The effects of disseminated intravascular coagulation which can be induced experimentally show a striking resemblance to those seen in various defibrination syndromes in human beings. But most of these effects can be either favorably modified or abolished experimentally by the administration of heparin.

The Shwartzman Phenomenon

Shwartzman found that if he prepared an animal by intravenous injection of a bacterial endotoxin and then re-injected the animal with the endotoxin in six to 24 hours, a sequence of events followed which in essence amounted to disseminated intravascular coagulation with the animal dying of characteristic renal cortical necrosis.[4] He also found that pregnant animals did not need a preparatory injection but would develop the syndrome after the first injection. It is postulated that preparatory blockade of the reticulo-endothelial system is obviated in pregnancy by the presence of increased amounts of factors I, II, V, VII, X, etc. The generalized Shwartzman phenomenon may also be produced experimentally in pregnant rats by feeding them an oxidized lipid diet.[5] Here there is a pathological development of degenerative areas in the placenta and of toxemia. The clot promotion is evidently initiated by placental clot-promoting agents in the degenerated areas of the placenta.

Particulate matter is also a factor in producing the generalized Shwartzman picture. Experimentally this condition can be produced by injecting amniotic fluid intravenously, but not by filtered amniotic fluid.[6] Other experiments done with colloidal suspension of materials such as kaolin and dextran have been used.[3,7] The colloidal material produces massive platelet agglutination, and the thrombotic sequence proceeds in the same manner as for bacterial endotoxin.

Clinical Problems

The clinical conditions where defibrination occurs are seen most frequently by the obstetrician. Premature separation of the placenta, retained dead fetus, amniotic fluid embolism, septic abortion, and hydatiform mole are conditions which the defibrination syndrome may complicate. It has been suggested that the syndrome may develop more commonly where there is some degree of toxemia of pregnancy.[8]

Premature Separation of Placenta

In premature separation of the placenta the mechanism is probably related to the fact that the placenta and decidua are rich in clot-promoting substance. Some of the cases of fibrinogenopenia appear to be due to generalized intravascular coagulation with defibrination. Perhaps others are due to deposition of large quantities of fibrin in the retroplacental clot.[9,10] Measurements of fibrin from these clots have been made with the quantity found adequate to explain the fibrinogenopenia. The presence of large amounts of the factors necessary in clot production is felt to lead to massive coagulation once the clotting cascade is started, which *per se* would overwhelm the reticulo-endothelial system.

Dead Fetus Syndrome

In females who harbor a dead fetus for longer than two weeks a gradual drop in fibrinogen frequently occurs. Actually a slight fibrinogen depression is usually seen in the days immediately following fetal death.[11] This is probably due to active retroplacental circulation absorbing clot-promoting products from the devitalized placenta. This phase does not produce serious fibrinogen depressions; in fact the fibrinogen level begins to rise again, probably because of a layer of fibrin being laid down between the devitalized placenta and maternal circulation. If the fetus remains undelivered, a second period of fibrinogen depression takes place. This is probably caused by degeneration of the ovular membranes which are no longer able to filter, but allow amniotic fluid particulate matter to enter the maternal circulation, with resultant clot promotion as mentioned in amniotic fluid experi-

ments in animals. Serious bleeding occurs in 1 to 2% of these cases. In the case of the dead fetus, the obstetrician may be forewarned of impending trouble by obtaining fibrinogen levels at weekly intervals as soon as a retained dead fetus is diagnosed.

Amniotic Fluid Embolism

Amniotic fluid embolism is a serious problem characterized clinically by the sudden onset of shock during labor or the first few hours after delivery. There may be a short prodrome of anxiety, restlessness, and vomiting. The patient becomes dyspneic and cyanotic, with signs of pulmonary edema. In patients who survive the initial period, a severe hemorrhagic diathesis develops. The initial phase is probably caused by marked platelet agglutination and platelet thrombi which block the pulmonary circulation. Serotonin liberated from the platelets could cause severe pulmonary vascular spasm as well. Knowing the clot-promoting ability of amniotic fluid, it is not hard to understand that there will be a decrease in factors I, II, V, VII, VIII, and in platelets, all concerned in the clotting process and leading to severe hemorrhage.

Septic Abortion

Septic abortion may be attended by fibrinogenopenia, hemorrhage, and other findings which parallel the Shwartzman phenomenon by endotoxin in the pregnant experimental animal.

Defibrination may occur temporarily in almost any surgical operation but is usually not of serious consequence. At times more serious defibrination may occur in operations on the lungs, which are rather abundant in coagulant material.

Metastatic Carcinoma

Metastatic carcinoma is sometimes responsible for activation of intravascular clotting or fibrinolysis. Hemangiomas may be associated with intravascular clotting and fibrin deposition within the tumor and activation of the fibrinolytic system. Intravascular hemolysis from mismatched blood, thrombotic thrombocytopenia, leukemia, snake bite, and drugs such as ristocetin* and dextran may all be associated with defibrination.[12]

*See Test Your Word Score Page 217.

Comments

It seems apparent in the majority of the instances of defibrination cited, the initial and most prominent factor seems to be coagulation with formation of fibrin. Other blood factors become depleted as they are consumed in the clotting process, so that the end result may be depletion of factors I, II, V, VIII, IX,

and of platelets in the circulating blood. When fibrin is formed, the fibrinolytic system will be activated. At times fibrinolysis seems to become an overwhelming factor and complicates the problem even further by lysis of other blood factors. Some of the products of proteolysis* are antithrombic, and heparin or heparin-like activity may be observed.

Appropriate laboratory studies are imperative but need not be complicated.

Diagnosis

A plan for study of patients suspected of having defibrination syndrome is presented in Table 2.

Stage 1 tests seek to establish four things: (1) the estimation of fibrinogen level, (2) the presence or absence of fibrinolytic activity, (3) the presence or absence of heparin-like activity, and (4) the platelet count. The status of fibrinogen, fibrinolysin, and heparin-like activity may be found by performing the thrombin time and fibrinogen titre with extended observations and modifications of these tests such as have been described by Hardisty and Ingram.[12]

After Stage 1 tests have been completed, further studies may then be helpful. The results of Stage 1 tests will determine the choice of these studies. If Stage 1 tests are normal, the problem most likely is related to a deficiency in the intrinsic or extrinsic system (Figure 1) other than fibrinogen or platelets. The prothrombin time and partial thromboplastin will be helpful here, and deductions may be made from the results of these tests (Table 2). If Stage 1 tests suggest heparin activity, a protamine titration will be helpful. If Stage 1 tests suggest the presence of defibrination, actual quantitation of fibrinogen will be helpful by gravimetric determination. The possibility of deficiency in other clotting factors may be estimated by performance of the thromboplastin screening test (Hicks-Pitney). Abnormalities of Stage 2 tests *per se* will not define the exact deficient factor(s). Hematologic consultation is probably indicated. For practical purposes of therapy, any factors which may be deficient as denoted by an abnormality in Stage 2 testing will be corrected by fresh plasma. As indicated in Table 2, Stage 3 results of therapy should be monitored by indicated studies.

*See Test Your Word Score Page 217.

Treatment

Therapy in the defibrination syndrome depends on the primary pathology and the type of hemostatic failure.

Removal of Causative Factors

Delivery by the natural route places considerably less demand on the hemostatic mechanism than caesarian section. It would seem desirable to allow natural delivery while resorting to appropriate hematological treatment.

Fibrinogen Infusion

If tests in Stage 1 (Table 2) indicate a fibrinogen deficit, fibrinogen infusion may be indicated. The dose to be given should be calculated to bring the patient's fibrinogen level up to 3 Gm./liter. About 15 minutes after the infusion the plasma concentration should again be determined, and about every two hours thereafter. There is about a 5% chance of homologous serum hepatitis developing in patients receiving fibrinogen. There is also a definite danger of aggravating fibrin deposition which is a factor in so many of these cases. The concomitant use of heparin to avoid this hazard will be discussed later.

Fresh Plasma

If Stage 2 tests (Table 2) suggest the presence of a thromboplastic factor deficiency, either congenital or acquired in the defibrination process, and if fibrinogen has failed to control bleeding, then whole fresh plasma should be given. One liter of fresh plasma should be given as a rapid infusion. This dose may be repeated twice a day if necessary.

Platelet Transfusion

Platelet transfusions may be used if the platelet count is under 100,000 and surgery is contemplated; but it is not necessary to use platelet transfusions if delivery is to be natural. Thrombocytopenia *per se* does not increase the risk appreciably in natural delivery.[13] Fibrinogen concentration should be 200 mg./100 cc. plasma and factor VIII levels adequate to ensure an uneventful spontaneous delivery.

Heparin Therapy

The results of heparin therapy in patients with defibrination has been gratifying. Platelet counts and fibrinogen levels have risen and bleeding has stopped when heparin has been given, only to recur when heparin was discontinued.[15,16] The presence of fibrinolysin activity cannot be construed as a contraindication to heparin, since the fibrinolysin is probably a secondary phenomenon, and it is doubtful that any further harm can accrue by the addition of heparin to a patient whose blood is not clotting. However, if any increased bleeding appeared to follow, the heparin could be quickly neutralized with protamine. Heparin should be used early along with replacement therapy of deficient blood factors in the defibrination syndrome. A method of calculating the dose of heparin based on the platelet count has been proposed by Bernstock and Hirson.[17] This entails dividing the platelet count by 50. For example: a patient with a platelet count of 100,000 would be given 2000 units of heparin intravenously, repeated every four hours. Platelets seem to exert some inhibitory effect on the effect of heparin.

Epsilon amino caproic acid is an effective inhibitor of fibrinolysin, but the appropriateness of its use in the defibrination syndrome without heparin is open to question. Definite cases of thromboembolism following its use have been documented.[18] Epsilon amino caproic acid has been shown to cross the placental barrier and therefore should be avoided in the immediate prenatal period.[19] When infused into the mother, epsilon amino caproic acid is able to inhibit fibrinolytic activity normally found in the newborn, an action which raises a serious possibility in view of some studies which would attribute hyaline membrane disease to failure of fetal fibrinolysis. Epsilon amino caproic acid is able to block the reticuloendothelial system. In view of data already presented on the Shwartzman phenomenon, this may represent a serious threat in the patient with defibrination. Perhaps the only clear-cut indication for epsilon amino caproic acid alone is in fibrinolysis seen in prostatic surgery. If one feels disposed to use epsilon amino caproic acid in defibrination syndromes because of an active fibrinolysin, it would seem appropriate to administer heparin also.[20] The usual dose is 4 Gm. in the first half hour followed by 1 Gm./hour for 12 hours, given intravenously.

Protamine may be indicated in certain cases where heparin-like activity seems prominent. A dose of not greater than 200 mg. may be given intravenously and repeated after one hour if necessary, preferably monitored by protamine titration. Excessive doses of protamine have an anticoagulant effect produced by binding with factors V and VIII. This takes place after heparin, which it binds preferentially, has been neutralized by protamine.

Operation Longevity

How should one live in order to reach a great age, free of diseases and breakages, and what hints can we learn from nature? Many recipes have been offered to the eternally optimistic human race. Centenarians have been asked how they spent their days. If one of these Nestors* replied that he had drunk wine mixed with honey every day, it was believed that an *elixir vitae* had been found. If another said that every evening he went to bed at the same time as the chickens, and poured ice-cold water over himself every morning, it was believed that this was the golden rule for life. Gorgias, who reached the age of a hundred and nine, replied to the question of how he had reached such a great age: "Because I have accepted as few invitations as possible to drinking sessions." Petrarch, too, remarks in his De Consolatione: "More men die from eating and excessive drinking than from the sword, and he who leads a moderate life will live to a ripe old age." Vegetarians think that they possess the key to health and longevity in their diet, the followers of Mazda in the strict eating of raw food and breathing exercises. It is impossible to list all the recipes and theories which have been put forward, and we confine ourselves here to dealing with two, on account of their originality:

Metschnikoff noticed that among the Bulgarian peasants there were more than two thousand centenarians. Investigating their way of life he discovered that they all drank large quantities of their national beverage, yoghourt. "Death resides in the bowels!" he declared. "We age as a result of the poisonous bacteria in our gut. The man who drinks yoghourt disinfects the bowel and will have a long life." For twenty years Metschnikoff obstinately tried to prove the validity of his hypothesis. He avoided alcohol and did not smoke; he examined his faeces daily for pathogenic bacteria and drank pints of yoghourt, although his palate yearned for something more spicy. He led a pathetic life in the cause of hygiene, but the results were meager—he died at the age of seventy-one.

If this experiment contained a grain of sense and logic, with a good prospect of success, the following undertaking is off the beaten track and peculiar. About 1880, Gustav Jaeger, an outstanding zoologist, advanced the theory that in order to remain healthy and attain a ripe age one must wear underclothes of animal fiber. The basis of his theory was as follows: "In the case of an animal, the excretions of specific odorants cause emotional disturbances, urges and instincts, and probably the formatory powers of the body and mind. The same thing presumably applies to human beings. But whereas with the animal these odorants are preserved in the pelt, they become weakened in man by porous clothing and are lost. This loss causes body and mind to wither and age. Wool like the pelt of an animal is capable of preserving these important constructive and forming materials. In this way body and mind remain healthy and fresh." Jaeger did not provide future generations with an experimental proof of his theory, or of the efficacy of Jaeger undergarments.**

Artificial Heart

II—Application of Nonpulsatile Radially Increasing Pressure Gradient Pumping Principle*

EDSON H. RAFFERTY, B.S. (Mech. Eng.)**

Background

THIS LABORATORY group has been conducting investigations into the suitability of nonpulsatile pumps in connection with the development of an artificial heart. One such pump, utilizing the force-vortex# principle of pumping, exhibited high efficiency and a remarkable capability for circulating blood at high flow rates without damage to the blood elements.[1] In an extension of the study of that type pump, lifting surface conveying channels were added to the basic unit. The findings recorded from studies carried out on the modified pump form the basis of this report.

Description

The nonpulsatile pump operates on the principle of radially increasing pressure gradients. Due to the extreme gentleness with which the force-vortex pump handled blood it was felt that it might be possible to trade off some of the qualities of atraumatic handling of the blood for increased efficiency. To accomplish this objective, lifting surface conveying channels were inserted into the basic force-vortex pump unit (Figure 1). These channels served to lift the fluid from the center of the shaft and quickly accelerate it out to the surrounding pump head space. The performance characteristics of this pump basically conform to Bernoulli's equation.

Methodology

The methodology was essentially the same as that carried out in the case of the force-vortex pump tested by this group,[1] and the same hematological studies were performed. The in-vitro circulation of blood in a semi-closed system was carried out at shaft r.p.m.s between 425 and 875. Pump efficiency determinations were made in the same manner as for the force-vortex pump.[1]

---

*See Part I, Minnesota Med 51:11, 1968.
**Veterans Administration Hospital, Houston, Texas.
†Veterans Administration Hospital, Syracuse, New York.
#See Test Your Word Score Page 217.

Results

Pump efficiencies in the order of 50% were obtained.

Figure 2 shows graphically the various flow rates and pressure heads attained at various r.p.m.s with water as the circulating fluid and with an input pressure of zero. Similar flows and pressures were achieved at a given r.p.m. when blood was substituted for water as the circulating fluid.

Continuous circulation of blood was maintained for six hours. Samples of blood were periodically taken from the reservoir for analyses. During these tests no hemolysis was detected by serial plasma hemoglobin determinations. No destruction of blood elements was detected during the period of circulation. A study of the platelets at the conclusion of the run revealed them to be normal in appearance and numbers. Defibrinization of the blood did not occur. Neutralization of the citrate effect with calcium chloride at the conclusion of the six-hour period of circulation resulted in prompt clotting of the blood (2½ minutes). Blood collected from the system at the completion of the run exhibited clot retraction of normal quality and time.

Discussion

The nonpulsatile pump described is one operating on a radially increasing pressure gradient pumping principle. This pump exhibits high efficiency in terms of converting mechanical energy into fluid flow. Additionally, it is atraumatic to blood. This model represents another type of nonpulsatile pump in a

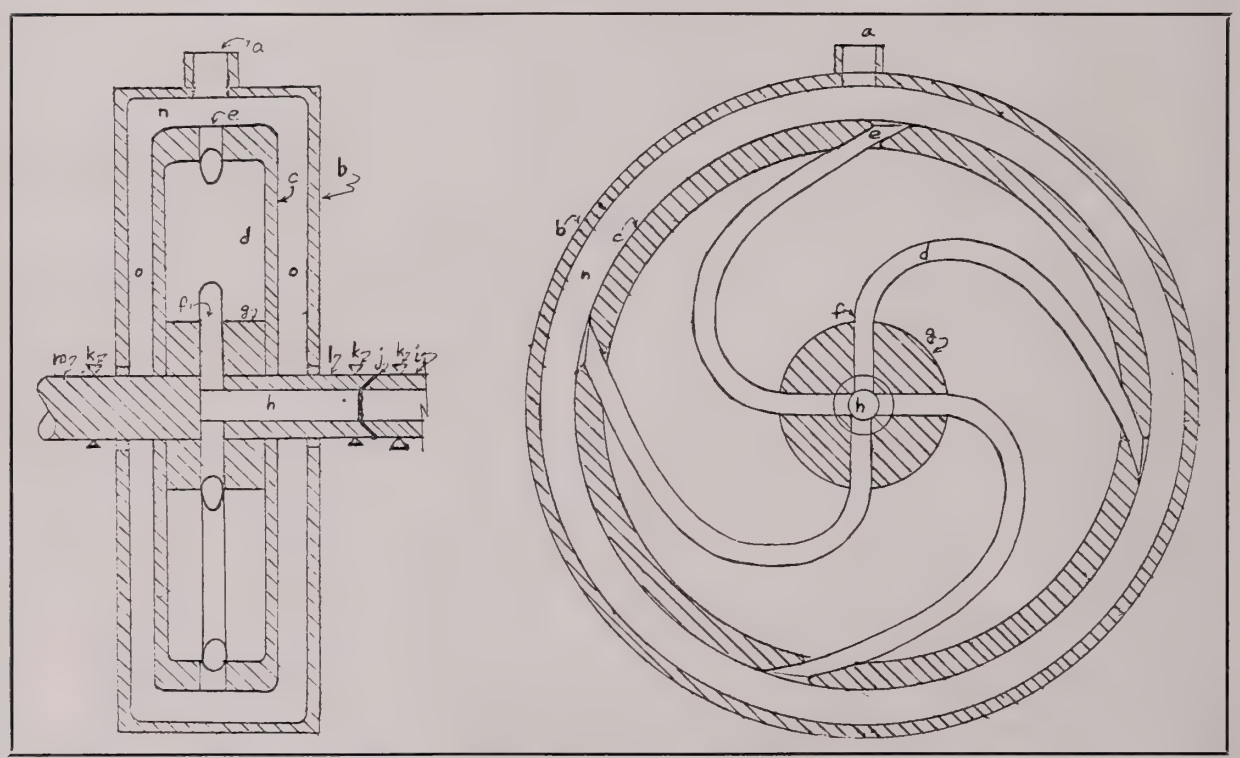

Fig. 1—Schematic cross-section of artificial heart: (a) pump outlet, (b) pump housing, (c) rotator, (d) rotator chamber, (e) rotator outlet, (f) rotator inlet, (g) shaft-to-rotator connector, (h) pump inlet, (i) stationary teflon inlet, (j) teflon-to-teflon seal, (k) bearings, (l) rotating inlet shaft, (m) stainless steel pump shaft, (n) head space, (o) side space. Outlet and inlet diameters, rotator	⅜"

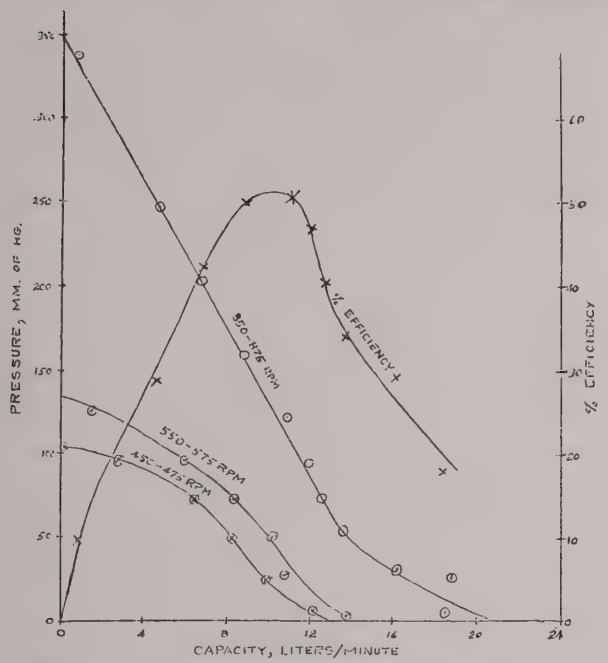

Fig. 2—Capacity vs. pressure and % efficiency.

continuing effort to optimize the performance of such units.

Although with this pump a slightly greater output was obtained when compared with the force-vortex pump, neither design necessarily represents that which will ultimately furnish optimum performance attainable for each given pump. In fact, it is probable that the design was not optimum, since design of the unit was tailored to ease of construction, visual testing capability, and ease of adaptability to testing modifications. Information obtained on stroboscopic study of fluid flow characteristics in the force-vortex model indicates that the curvature path preselected for the conveying channels in the modified pump was in retrospect of suboptimum design for gentlest handling of the fluid. Improvement in performance in this regard should follow a correction of this design feature.

As in the case of the force-vortex pump, blood utilized for testing the current pump was pooled from unfasted sick dogs.

Conclusions

A nonpulsatile pump operating on a radially increasing pressure gradient pumping principle has been described. This pump performed at high efficiency and was atraumatic to blood despite suboptimally designed conveying channels. As anticipated, an increase in efficiency of this pump over the force-vortex pump was obtained. For the period tested and with the particular tests employed, there was no detectable increase in trauma to the blood. Because of these favorable characteristics, continued studies are in progress to optimize such a unit for eventual use as an artificial heart as well as for extracorporeal uses.

Acknowledgments

We wish to extend our appreciation to Dr. Fred B. Vogt, Chairman, Department of Biomedical Engineering, Graduate School of Biomedical Sciences at Houston, and Louis Meharg, Ph.D. (E.E.) of the Department of Biomedical Engineering, Graduate School of Biomedical Sciences at Houston, for their review and analysis of our results and calculations.

There is more felicity on the far side of baldness than young men can possibly imagine.—L. P. Smith

Mr. President—Your Health*

Rutherford B. Hayes (1822-1893)

Any American doctor advocating moderation and equanimity to a patient can point with national pride to Rutherford B. Hayes, the Republic's nineteenth President.

Never husky, yet healthy and athletic, young Rutherford hunted, hiked, fished, swam, and skated—on one momentous occasion breaking through the ice. It was in this predicament that he demonstrated his innate composure by not struggling or panicking but serenely waiting to be rescued.

At college he went in for track, also bare-handed baseball until, after injuring several of his fingers, he decided that the sport of gloveless baseball was not for him but had best be left to juveniles. His hiking endurance and capacity were once ruggedly demonstrated by his walking home from college forty miles in twelve hours through four-inch-deep snow.

When a young practicing lawyer in his twenties Hayes suffered from frequent sore throats, an affliction finally culminating in an attack of quinsy, which was treated and apparently cured by rest, cathartics, and codliver oil.

While he was serving as a colonel in the Civil War at the Battle of South Mountain, Hayes' left arm was fractured by a bullet. After a comrade had stanched the hemorrhage that followed, Hayes struggled to his feet to continue fighting, but collapsed and had to be carried off the field. Later, in an engagement at Fishers Hill and Cedar Creek, his horse was shot out from under him and his ankle painfully wrenched. Undaunted, he promptly mounted another steed and heroically proceeded into action from where he had left off. Nor was this the only time his horse was shot out from under him! On three more occasions enemy fire brought down his mount—without disturbing its rider's magnificent aplomb.

In his middle years as a Representative from Ohio, Hayes was a handsome man with perfect teeth and vision so good as not to require glasses, an anomaly doubtless due to early myopia offset by later presbyopia. He maintained superb physical fitness by daily setting-up exercises and brisk walks. In his pursuit of the Greek ideal of moderation he drank coffee and tea very sparingly; from tobacco and alcohol he abstained completely.

As President, Hayes continued his schedule of exercise and his practice of moderation, permitting himself only one cup of coffee for breakfast and one cup of tea with his lunch.

Even after retirement Hayes became neither complacent nor careless in his habits but meticulously maintained the straight and narrow path he had resolved on. He never kept late hours, preferring to retire before inside illumination was required.

Nevertheless, in Hayes' late sixties age began to creep up on him—with mild but progressive evidences of irreversible deterioration: impaired memory and hearing and diminished vigor and agility. Of his aging, however, it can well be said: Time alone was the pen!

In early January 1893 Hayes contracted a severe cold with a cough, followed in a few days by acute chest pain and shock. Two weeks later, while confined to his bed under sedatives he suffered a coronary thrombosis which terminated his life, at the Biblically allotted years of three score and ten.

Critique of the Provocative Intradermal Food Test*

KENNETH J. JOHNSON, M.S., M.D.**
Bismarck, North Dakota

"Food allergy has been recognized as a cause not only of gastrointestinal symptoms, but also of a variety of functional disorders, including asthma, allergic rhinitis, urticaria, angioedema, eczema, migraine, and other bizarre syndromes."[1] The diagnosis of food allergy, however, has often been difficult or tedious. "Skin tests for foods are held in low esteem because of so many cases where a positive test was not confirmed clinically, or where a negative test occurred with certain clinical evidence of allergy to that food. Many allergists disregard the results of skin tests with foods, and some have discontinued skin testing with foods, depending rather on clinic trial-and-error diets, elimination diets, or intentional-feeding diets."[2]

With such a situation existing, then, it was noteworthy when the provocative intradermal food test was proposed.[3] The provocative injection of solution of food extract would provoke or elicit the same symptoms to a small degree that the food caused when ingested. The size of the skin reaction was not significant. The symptoms would then be relieved by a higher dilution of that food extract, called the neutralizing dose. Later papers[4,5,6] confirm the reliability and safety of the procedure. Although I have not found any reference in the literature claiming this test to be unreliable or impractical, some allergists may regard it as controversial. Therefore, an evaluation of patients tested by this procedure seems in order if the field of medicine is to continue to progress. Because there is a great need for an accurate simple quick method of diagnosing food allergy (or idiosyncrasy or intolerance or hypersensitivity or reaction) a procedure such as the provocative intradermal food test should be either confirmed and upheld, or refuted and discredited. It certainly should not be ignored.

*Presented at the North Central Allergy Society, Madison, Wisconsin, May 6, 1967, and at the American Association for Clinical Immunology and Allergy, Las Vegas, Nevada, November 28, 1967.

**Quain & Ramstad Clinic, Bismarck, North Dakota.

Methods of Study

With this in mind, I present cases of positive reaction to one or more foods by the provocative intradermal food test. To avoid the factor of suggestion, the patient was not allowed to know which food was being tested, nor whether a particular injection was expected to provoke or exacerbate or relieve a symptom, or to have no effect. A detailed food allergy or intolerance history was obtained in every case; symptoms were noted as to whether they were associated with eating of a food and cleared with avoidance of that food, and also whether they recurred with resumption of that food in the diet. Thus specific food allergy, elimination, and intentional feeding were studied in relation to the findings of the provocative intradermal food test.

(In my series the provocative dose was 0.05 cc. of 1:5 dilution of a commercial 1:20 food concentrate—#1 dilution—waiting for 10 minutes for appearance of symptoms, and if no change a four-minute wait for symptoms after a subsequent injection of 0.02 cc. of 1:125 dilution of that concentrate—#3 dilution.)

Results

This series of positive reactors consisted of 110 patients. Four failed to follow their diet, so could not confirm or refute the accuracy of the findings of the provocative intradermal food test. Six were lost to followup. Of the remaining 100 patients, in 86 the symptoms cleared on avoiding the offending food and recurred again on eating the food. In nine the symptoms improved but did not clear completely on avoiding the offending food, but worsened considerably again on eating the offending food. Thus the provocative intradermal food test confirmed the dietary identification of the specified food responsible for the symptoms in 95 out of 100 cases (95%). The presenting diagnoses of these 100 patients are given in Table 1.

Milk, Corn and Wheat

Among the patients in whom the symptoms cleared or greatly improved on avoiding the specific food in their diet, milk was the most frequent allergen (48 patients), corn the next most frequent (41 patients), with wheat a close third (38 patients). Thirteen foods were found to be allergenic in this series. See Table 2.

Multiple Foods

Among those 95 patients who benefited by following their allergen-free diets, the number

of foods found to react by the provocative intradermal food test in each patient varied from one to eleven. One patient with urticaria who reacted to both wheat and egg by the tests stated later that on these occasions her hives cleared on avoiding eggs and recurred on eating them, but that she noticed no difference in her hives whether she ate wheat or avoided it. One 10-year-old patient with reactions to milk and corn confirmed this result with milk but failed to confirm it with corn. Whether he and his mother succeeded in having him follow a truly corn-free diet consistently is not certain. Because corn is present in some 130 foods in the form of corn oil, corn starch, corn sugar, or corn syrup, it is by far the most difficult to avoid.[7] One woman with allergic rhinitis confirmed potato, beef, and corn but not wheat. See Table 3.

Contradictory Observations

An evaluation of those five cases where the elimination diet failed to improve or relieve the symptom and the intentional-feeding diet failed to induce the symptom reveals no obvious common factor. The order of testing of the provocative food and the neutralizing dose was different in each of the five cases. The provocative food was different in each. The sex and ages differed. The presenting diagnosis or chief complaint differed: two had allergic rhinitis, one urticaria, one ulcerative colitis, one nonspecific gastrointestinal symptoms. See Table 4.

The most plausible explanations as to why the testimony of these five patients contradicted the findings of the clinic testing are three:

Another Factor Contributed to the Symptoms.

Two patients were also allergic to house-dust; one had phlegm in her throat as the provoked symptom; the other had an increase in her postnasal drip, both common symptoms of house-dust sensitivity.

Inaccurate Reporting

One patient denied relief of stomach pressure and pains and borborygmi from avoiding corn (if he actually did avoid all forms of corn completely) and denied worsening of symptoms with eating corn, yet he stated he got enough relief from corn propetans[8] to request a refill when his supply was used up!

Coincidental Symptoms.

One would suspect that a symptom occurring after the provocative dose might be coincidental, especially if it occurred only once and was very mild, e.g., *one* scratch, *one* cough, or *one* burp. It may be that I misinterpreted the significance of the symptoms. Such symptoms as burping, scratching, and coughing were actually counted and recorded as to time during both control periods and test periods; a positive result was called only when there was a decided increase in symptoms during the test period as compared to the control periods before and after. A frank attack of bronchial asthma was not elicited by any test; at best barely audible wheezing and increased respiratory excursion were observed. This would be expected, since the symptoms provoked are symptoms "in miniature."

The patient may have failed to eat the offending food within the preceding four days.

Value of Provocative Testing

Negative Results

Is a negative result reliable? The data on those patients who had only negative findings were collected; only 25 cases were found whose allergenicity had been suspected. Of those 25, 23 confirmed the negative tests by failing to show relief of symptoms on avoiding a suspected food, and failing to show worsening of symptoms on eating that food. Two did give a history of food intolerance confirmed by diet manipulation. The first was a 35-year-old male with ulcerative colitis, who declared he got indigestion from milk; the second was a 79-year-old male with complaint of burning urine, who declared his urine burned whenever he drank coffee. Yet no symptoms

TABLE 4

Data on Five Patients Whose Positive Tests Were Contradicted by Diet Trials.

Age, Sex	Diagnosis	Prior Symptoms	Positive Reactors	Order of Food Tested	Induced Symptoms
53 f	all. rhin.	yes	coffee	fourth	phlegm in throat, clearing throat, hawking
64 f	all. rhin.	yes	milk	first	more postnasal drip
28 f	urticaria	yes	egg	second	itch (one hive appeared)
29 m	ul. col.	no	orange, wheat	second, sixth	full feeling, abdominal cramp, burp
40 m	G. I.	no	corn	third	pains in abdomen, borborygmi, pressure in stomach

were elicited by the provocative intradermal food test for milk in the former, or for coffee in the latter. Although 25 cases is a small number from which to draw conclusions, they do suggest that this test is about 92% accurate, in ruling out a specific food allergy.

The ages of the patients are shown in Table 5. To give the reader an idea of how thorough or incomplete the testing was, the number of foods tested on each patient is given in Table 6.

Otorhinolaryngological Cases

The provocative intradermal food test is of most value in otorhinolaryngological cases, since a large number of cases of food allergy have as their symptom increase in mucin production, noted by the patient as formation of phlegm in the nose and throat. In the present series 63 of the 100 patients had symptoms referable to the eye, ear, nose, or throat. This may explain why the ear-nose-and-throat specialists use this test more widely than do the internal medicine and pediatric allergists.

Diagnostic Advantage

This technique for diagnosis of food allergy has several advantages. (1) It is more accurate than skin tests for foods measured by local skin reactions, which "are dependable in less than 50% of the cases."[9] (2) It is more informative; it not only demonstrates a reaction to the food but shows what symptoms that food produced. (3) It gives the answer in one clinic visit, not after many days, such as the elimination diet and intentional feeding require. (4) It eliminates the diagnostic necessity of following a rigid, difficult, restrictive diet without respite day after day, a tedious demand that very few patients have the ability, motivation, or will power to pursue. (5) It is safe; I have never had a serious reaction to one of the injections, but I have never tested for a food which has already been proven to cause a severe reaction, and I do not recommend testing in such a case. (6) It provides another worthwhile method of diagnosing food allergy.

Disadvantages

This method of testing for food sensitivity has several disadvantages, however. (1) It is slow; with the technique used a minimum of 10 to 14 minutes is required for each food, and only one food at a time can be tested, unless one is screening. If several foods are tested at the same time and a positive response is obtained, each food must then be tested individually. (2) It is tedious and demanding; one must watch the patient constantly with no interruptions for as long as the test runs. If not, symptoms will be overlooked and a false negative report will result. (3) It is difficult to interpret as it is sometimes uncertain whether a trivial symptom is due to the injection or is coincidental. Measurement of symptoms and degree of lessening or worsening must be inexact because of the subjective nature of the process; degree of response may vary, just as in allergic rhinitis or bronchial asthma on different occasions upon identical exposure to an inhalant. The method is necessarily highly subjective because the test elicits symptoms. Placebos were used to test foods to which the patient was not expected to react because of negative history of intolerance to that food.

A double-blind method was not feasible, since I had to determine which foods were suspect by history, then test for these foods. (4) It requires intelligent cooperation on the part of the patient. If the patient fails to inform the physician of the occurrence of a symptom, or cannot discern a change in his psyche, a significant symptom will be missed. (5) The patient must have been off anticholinergic, antihistaminic, and sympathomimetic drugs for at least 1½ days (and, ideally, steroids for a longer time); but this is also true with scratch and intradermal tests. (6) The patient must have eaten the offending food within the last four days to yield a positive test.

Comments

The results of correlation of test findings with diet findings are summarized in Table 7.

TABLE 7
Summary of Results

		DIET	
		+	−
P.I.F.T.	+	95	5
	−	2	23

After avoiding the offending food for a long enough time, the patient usually loses his sensitivity to it; thereafter, eating it—at least in moderation—produces no symptoms. At this stage he is apt to disbelieve he ever was allergic to it.

It is not evident that food allergy patients represent truly atopic* individuals; in fact, there is more evidence that they do not. The rare patient who reacts anaphylactically to nuts or seafood probably is an "atope," but this type of patient wasn't studied. The great majority of patients with intolerance to food do not have atopic histories and have shown no reagins in their skin or food antibodies in their serum and do not readily demonstrate eosinophilia with a delayed reaction to the food. Some allergists wish to restrict themselves to reagins; if they do they will not concern themselves with the bulk of food allergy. Food allergy is a very controversial area; for this reason it is imperative that techniques like the provocative intradermal food test be studied and discussed, not neglected.

*See Test Your Word Score Page 217.

Summary

1. The findings on diet manipulation by elimination and intentional feeding were compared with the results of the provocative intradermal food test, to evaluate this test's accuracy.

2. In 100 cases giving positive tests 95 patients substantiated these by showing alleviation of symptoms on avoiding the specific food, and recurrence on resuming the food. This would indicate a 95% correlation between the two methods of diagnosing food allergy.

3. In 25 cases giving negative tests 23 failed to show a change in symptoms whether they did or did not eat each food giving a negative test. This would indicate a 92% correlation.

4. The provocative intradermal food test has certain advantages and disadvantages but is nevertheless a worthwhile addition to the practitioner's diagnostic methods. The results must be accepted with caution, however, for unless one becomes an expert he should double-check the results by other means, such as by diet manipulation.

Truth

He who does not know truth at sight is unworthy of her notice.—Blake

Beckie

Not that I never made mistakes. There was Beckie, for instance. Probably every hospital has its oddities, but among those at Gouverneur Hospital in my day, Beckie easily led the list. She was a character Balzac might easily have written about. Beckie was our prima donna of malingerers, and don't think that I am telling you about any ordinary performer. No indeed! She had a method and technique so unique and productive of results that she fascinated us all. When the outside world got too cruel she knew how to enter a hospital and secure the best skill and attention, food, and shelter.

Beckie believed in the dramatic and when she decided that the time had come for another hospital sojourn, she would invariably pick out a street corner where there was plenty of room for a sympathetic crowd to gather, and gather they always did. She would have to decide what ailment to fake.

It must be remembered that methods of diagnosis were more primitive then, and lacking all the tests of later days, greater reliance had to be put on the patient's own testimony. On one occasion I was told she had produced indications of acute appendicitis so convincing that an immediate operation was performed, and rumor hath it that it was none other than John F. Erdmann himself who removed a perfectly normal appendix. This, however, was before my time.

Was it surprising then that, in spite of the reputation of this malingerer, I, a green young doctor, should not have spotted Beckie when it was my turn to be called. I found the usual crowd, surrounding a pathetic little woman writhing apparently in death agonies. She seemed to have a great tumor mass in her stomach region suggesting an intestinal obstruction. I didn't even think of considering that her symptoms might be feigned, through some power to control and contract muscles in an unusual way. Instead the patient got at once my best care and was rushed to the hospital at top speed, put to bed immediately and with all the nurses on the service rushing with restoratives and sedatives for her pain. Immediately I reported this patient to my superior officer, and when he arrived he at once recognized Beckie, much to his glee and my discomfiture. However, Beckie was equal to the occasion and now that she was in the hospital with a good bed, food, and shelter, she did not intend to convalesce too rapidly.

Beckie took her time and several days elapsed before she allowed her phantom tumor to disappear. When finally she was ready for discharge, I believed she could stand some straight talk and I said to her: "Beckie, you know you are a wonderful fake. Now, if ever you throw a fit on a street corner again and I am on the bus, I'll arrest you and take you to the station house, not to the hospital. Perhaps you do not know it, but when I am on the ambulance, I am a Sergeant of Police."

Several months must have elapsed, and I had forgotten about Beckie, when one day an urgent hurry call came in. As we neared the scene of action the crowd parted to make room for the ambulance and leaning far out I made a quick survey of the situation before the bus had come to a stop. In those few seconds I caught the furtive eyes of Beckie and she knew perfectly well who I was. Before I could reach her she gave one mighty jump, and with the agility of a gazelle, began running in the opposite direction. As she fled she picked up speed and I doubt if any of the bluecoats on the police force could have caught her. She may be running still for all I know, for I never saw or heard of Beckie again while I was at Gouverneur Hospital.*

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

new evidence for TAO® (triacetyl-oleandomycin)

a macrolide antibiotic for the frequently seen respiratory infection in the office and for a problem pathogen* in the hospital.

*Staphylococcus aureus

study I[1]

Results of a 1967 in vitro—in vivo correlation study involving 116 patients with Gram-positive coccal infections in five institutions. All patients were given TAO prior to determining the susceptibility of the offending organism.

97.0%
of the organisms were susceptible to oleandomycin*

98.0%
of the patients responded favorably to TAO® (triacetyloleandomycin)

*In some cases more than one pathogenic organism was isolated from the patient.

study II[2]

Effect of oral therapy with TAO, erythromycin, and cloxacillin on the survival time of Rhesus monkeys after intravenous inoculations of lethal doses of staphylococci, phage type 80/81.
(8 monkeys in each group)

conclusion:

*Under the conditions of this study and the doses employed, it was found that

TAO® (triacetyl-oleandomycin)

was far superior to erythromycin, as was cloxacillin, a bactericidal agent, and of particular interest, "...bacteriostatic triacetyloleandomycin was as effective or perhaps superior to cloxacillin in preventing lethal (staphylococcal, phage type 80/81) infection."

*It should be pointed out that results obtained in an experimental study of this nature may not necessarily be directly extrapolated to the clinical situation as it pertains to man.

TAO Rx Information

INDICATIONS: Include streptococci, staphylococci, pneumococci and gonococci. Recommended for acute, severe infections where adequate sensitivity testing has demonstrated susceptibility to this antibiotic and resistance to less toxic agents. **CONTRAINDICATIONS AND PRECAUTIONS:** Not recommended for prophylaxis or in the treatment of infectious processes which may require more than ten days continuous therapy. In view of the possible hepatoxicity of this drug when therapy beyond ten days proves necessary, other less toxic agents should be used. If clinical judgement dictates continuation of therapy for longer periods, serial monitoring of liver profile is recommended, and the drug should be discontinued at the first evidence of any form of liver abnormality. When treating gonorrhea in which lesions of primary or secondary syphilis are suspected, proper diagnostic procedures, including darkfield examinations, should be followed. In other cases in which concomitant syphilis is suspected, monthly serological tests should be made for at least four months. Contraindicated in pre-existing liver disease or dysfunction, and in individuals hypersensitive to the drug. Although reactions of an allergic nature are infrequent and seldom severe, those of the anaphylactoid type have occurred on rare occasions. When used in streptococcal infections, therapy should be continued for ten days to prevent the development of rheumatic fever or glomerulonephritis. The use of antibiotics may occasionally permit overgrowth of nonsusceptible organisms. A resistant infection or superinfection requires re-evaluation of the patient's therapy. In the event such occurs with this drug the medication should be discontinued, and specific antibacterial and supportive therapy instituted.

HALT DIARRHEA!
SHERIFF

LOMOTIL®

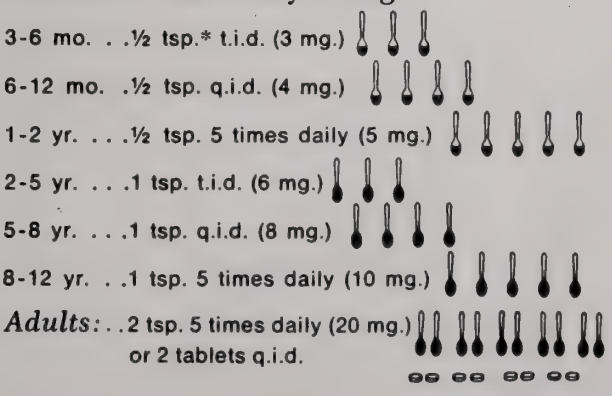
TABLETS / LIQUID

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride . . . . . .2.5 mg.
(Warning: may be habit forming)
atropine sulfate . . . . . .0.025 mg.

Halts Diarrhea Promptly

in children with . . . Gastroenteritis ▪ Spastic bowel
Influenza-like infections ▪ Antibiotic-induced diarrhea

Lomotil helps get children with diarrhea off toast and tea and back to normal diets and normal activity with gratifying dispatch. ▪ Lomotil lowers intestinal motility and permits absorption of excess fluid. This usually controls diarrhea promptly. ▪ Moreover, lowered intestinal motility achieved with Lomotil often relieves the abdominal cramps and discomfort so distressing to children.



Precautions: Lomotil is a Federally exempt narcotic preparation of very low addictive potential. Recommended dosages should not be exceeded, and medication should be kept out of reach of children. Should accidental overdosage occur signs may include severe respiratory depression, flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia; continuous observation is recommended. Lomotil should be used with caution in patients with impaired liver function or those taking addicting drugs or barbiturates.

Side Effects: Side effects are relatively uncommon but among those reported are gastrointestinal irritation, sedation, dizziness, cutaneous manifestations, restlessness, insomnia, numbness of the extremities, headache, blurring of vision, swelling of the gums, euphoria, depression and general malaise.

Dosage: The recommended initial daily dosages, given in divided doses until diarrhea is controlled, are:

Children: Total Daily Dosage

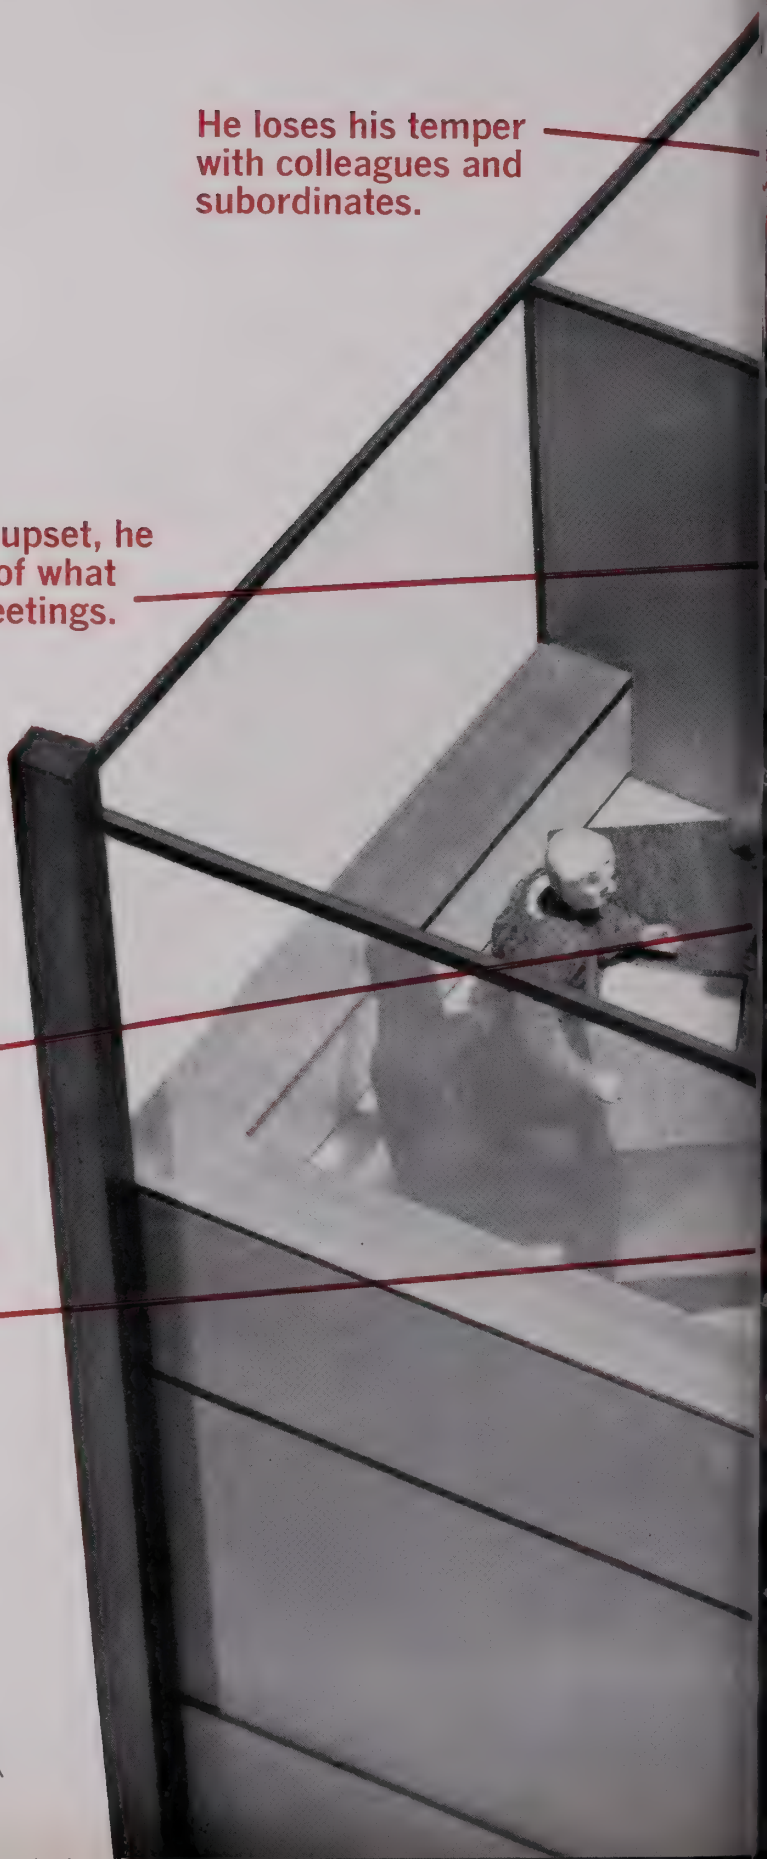
3-6 mo. . .½ tsp.* t.i.d. (3 mg.)
6-12 mo. .½ tsp. q.i.d. (4 mg.)
1-2 yr. . . .½ tsp. 5 times daily (5 mg.)
2-5 yr. . . .1 tsp. t.i.d. (6 mg.)
5-8 yr. . . .1 tsp. q.i.d. (8 mg.)
8-12 yr. . .1 tsp. 5 times daily (10 mg.)
Adults: . .2 tsp. 5 times daily (20 mg.)
or 2 tablets q.i.d.

*Based on 4 cc. per teaspoonful.

Maintenance dosage may be as low as one-fourth the initial daily dosage.

SEARLE *Research in the Service of Medicine*

When the agitated businessman goes to work...



He goes home at night and takes it out on his family.

He loses his temper with colleagues and subordinates.

Emotionally upset, he misses half of what is said at meetings.

He is always fearful about his standing with the boss.

He just can't seem to settle down to his work.

for moderate to severe anxiety

Mellaril® (thioridazine) 25 mg. t.i.d.

SANDOZ

See following page for additional product information.

When the agitated businessman goes to work...

Anxiety that *seriously interferes* with the individual's performance at work, at home, or in the community may be regarded as *moderate to severe* in degree.

Mellaril often recommends itself to the treatment of moderate to severe anxiety because it

- helps control the most frequent symptoms: marked tension, agitation, apprehension, restlessness, hypermotility
- often alleviates anxiety-induced somatic complaints
- frequently helps strengthen emotional resources
- helps the patient maintain realistic contact with environment, closer harmony with family

Thus, when you consider the anxiety moderate to severe... consider Mellaril.

Contraindications: Severely depressed or comatose states from any cause, and in association with or following MAO inhibitors; severe hypertensive or hypotensive heart disease.

Precautions: Hypersensitivity reactions (e.g., leukopenia, agranulocytosis) and convulsive seizures are infrequent. Pigmentary retinopathy has been observed where doses in excess of those recommended were used for long periods of time. May potentiate central nervous system depressants, atropine, and phosphorus insecticides. Where complete mental alertness is required, administer the drug cautiously and increase dosage gradually. In addition, orthostatic hypotension (especially in female patients) has been observed. Epinephrine should be avoided in treatment of drug-induced hypotension.

Side Effects: Pseudoparkinsonism and other extrapyramidal disorders are infrequent; drowsiness, especially in high doses early in treatment, may occur; nocturnal confusion, dryness of the mouth, nasal stuffiness, headache, peripheral edema, lactation, galactorrhea, and inhibition of ejaculation are noted on occasion; photosensitivity and other allergic skin reactions may occur but are extremely rare.

Before prescribing, see package insert for full product information.

for moderate to severe anxiety

Mellaril®
(thioridazine)
25 mg. t.i.d.

SANDOZ

mudrane®

for

- EMPHYSEMA
- ASTHMA
- CHRONIC BRONCHITIS
- BRONCHIECTASIS

The fast-disintegrating uncoated tablet gives relief in 15 minutes

Each tablet contains:

Potassium Iodide	195 mg.
Aminophylline	130 mg.
Phenobarbital, Caution: May be habit forming...	21 mg.
Ephedrine HCl	16 mg.

FEDERAL LAW PROHIBITS
DISPENSING WITHOUT PRESCRIPTION

Precautions: Usual for aminophylline-ephedrine-phenobarbital. Iodides may cause nausea, long use may cause goiter. Discontinue if symptoms of iodism develop.

Iodide contraindications: tuberculosis, pregnancy.

DOSAGE

One tablet, with full glass of water, 3 or 4 times daily.

Dispensed in bottles of 100 and 1000 tablets.

MUDRANE GG—Formula, dosage and package identical to Mudrane—*except*—100 mg. glyceryl guaiacolate replaces the potassium iodide. The value of Mudrane cannot be enjoyed by a small group in which K.I. is contraindicated. Mudrane GG is prepared for this group.

MUDRANE GG ELIXIR—Four 5 cc teaspoonfuls is equivalent to one Mudrane GG tablet. Dosage adjusted to age and weight of child. Mudrane GG Elixir is for pediatric patients and those who think they cannot swallow tablets. Dispensed in pint and half gallon bottles.

Editorials

Factors Influencing the Level of Lower Limb Amputations in Peripheral Vascular Disease

In recent years there has been a conservative trend in lower-limb amputation, as Dr. Kane* ably brings out in his article: *Factors Influencing the Level of Lower Limb Amputation in Peripheral Vascular Disease.* For the most part these amputations through the foot or the calf have provided the patient with a more usable limb than if the above-knee amputation had been done. Nevertheless, failures of these lower amputations to heal continue to occur, especially if there has been no improvement in circulation.

Reconstructive vascular procedures can be performed with less tissue destruction and less trauma to the patient than occur in a major amputation. The technique of venous by-pass grafting to the distal popliteal artery has been successfully extended to the anterior and posterior tibial arteries. When this level of good flow is accomplished it almost assures healing to the mid-foot level.

Although the vascular limb disease of diabetics is notable for the prevalence of endarterial obstruction, superficial femoral obstruction does occur; and if a diabetic develops ischemia from an obstruction to the superficial femoral artery he may well get a very satisfactory result from a by-pass graft and should not be excluded from a reconstructive procedure simply because he is a diabetic.

Finally, a femoral arteriogram to help determine whether a reconstructive procedure is possible can be performed with a very low incidence of complication by utilizing local anesthesia; and it should be done and evaluated on all candidates for amputations, excluding only those cases wherein the added length of limb salvage would be of no significant benefit to the patient.

Harrison H. Farley, M.D.
Minneapolis, Minnesota

*See page 179.

My books are water: those of the great geniuses are wine. Everybody drinks water.—Mark Twain

---

Any man whose actions leave his wife speechless really has hit on something.—Changing Times

Before prescribing, see complete prescribing information in SK&F literature or *PDR.* A brief precautionary statement follows.
Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder neck obstruction.
Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.
Usage in Pregnancy: Use cautiously, especially in the first trimester. *Note:* The iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake; discontinue 'Ornade' one week before these tests.
Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible side effects of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported but no causal relationship has been established.

Complications of Bronchial Asthma

Intelligent symptomatic treatment of a patient with bronchial asthma involves an understanding of the underlying pathophysiologic processes. Management should be directed toward these primary processes—edema, bronchospasm, and tenacious secretions, along with their secondary consequences such as hypoventilation, dehydration and increased work of breathing. The therapeutic attack must also consider the complications resulting from these processes, such as pneumothorax, infection, atelectasis, subcutaneous emphysema and cardiac complications, as these may aggravate the primary condition and endanger the life of the patient.

Spontaneous development of mediastinal emphysema may be trivial or widespread. Two cases have been reported by David E. Dines and Gustavus Peters in the April issue of Minnesota Medicine.[1] As pointed out, this condition occurs more frequently than the medical literature indicates. Most of the cases reported occurred in patients whose asthma was of several years' duration. The outstanding sign is a peculiar, loud, crackling, bubbly sound synchronous with the heart beat. X-ray examination helps to confirm the diagnosis. Although mediastinal emphysema may result in severe respiratory distress and a shock-like state, it has not by itself been very serious in patients with asthma. This probably is because in the older child and adult the mediastinal air is decompressed rather easily into the neck and usually no pneumothorax develops. The average duration of this complication is between seven and 10 days.[2]

Complicating infections may play a major role in the prolongation of an acute attack of asthma. Infections need not be bacterial since mucosal edema and secretions due to viral disease may be just as harmful. It is therefore important to identify the causative organism.

Occasionally spontaneous pneumothorax is seen in patients with asthma. This condition is probably produced by the rupture of a bleb* from over-distension during an attack. In such instances, the patient is likely to have his breathing further embarrassed, and the condition may become serious. Because of the shortness of breath and the possible coexisting emphysema, the physical findings may be somewhat masked. However, careful physical examination showing the filled-out intercostal spaces, the enlarged chest wall, the tympanitic note, the absence of breath sounds and the displacement of the heart away from the affected side should be sufficient to make the diagnosis, which may be definitely confirmed by x-ray examination.

Spontaneous fracture of the ribs in asthma is rare. This usually results from violent coughing in which unusual muscular strain is applied to the ribs. Localized pain is a characteristic feature. Splinting because of the pain may aggravate the asthma.

Atelectasis is probably more commonly present than can be diagnosed. This complication may occur in asthma from the obstruction of a small or large bronchus by a mucus plug, following a general anesthetic or with a foreign body in a bronchus. Small areas of atelectasis must occur from time to time in asthma, giving rise to no apparent symptoms. When the plug remains for some time and there is an infection, bronchiectasis or pneumonitis may develop. The larger the area of atelectasis, the more serious is the condition. Onset may be sudden and the patient may become seriously ill. To compensate for the collapse of a whole lobe, the heart and mediastinum shift to the affected side and the diaphragm becomes elevated. This can be readily demonstrated by x-ray examination.

The relationship of heart failure and bronchial asthma is controversial. Certainly heart failure can be seen in elderly patients following the onset of asthma. Regardless of whether or not it is due to uncomplicated asthma the condition should be treated promptly. In addition to the above-mentioned complications, it must be remembered that people with asthma may have other diseases.

A patient with bronchial asthma should be treated with vigor—but cautiously. Complicating conditions in the asthmatic lung should be recognized and treated immediately, as they may be more important than the primary processes under consideration.

Definitive Cosmetic Correction of Facial Skin Losses

In cases of accidental loss of skin about the face, if the area can not be closed by undermining of the skin edges with direct approximation, application of a free skin graft to the open defect is indicated. If the avulsion is relatively clean or can be converted to a clean wound by debridement, primary closure of the defect with a free graft may be done. If the wound is jagged and viability of tissues is in question, debridement and dressing only, with secondary closure by grafting five to ten days later, is preferable.

*See Test Your Word Score Page 217.

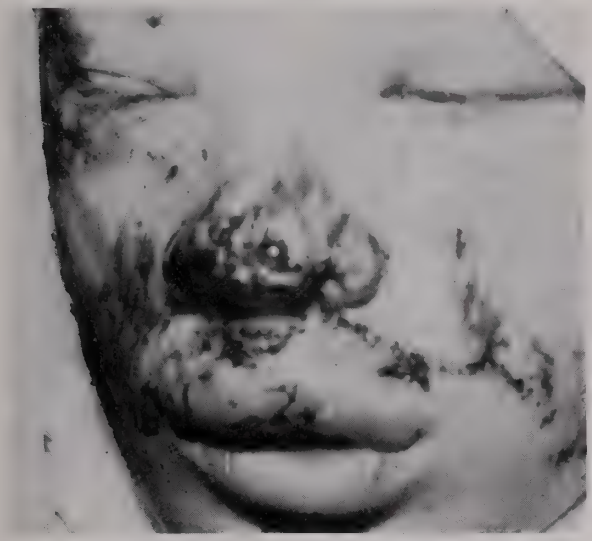

Fig. 1—Avulsion of 3 × 4 cm. area of skin over the tip and left side of nose. A thick split-thickness skin graft, taken from the clavicular region, was applied to cover the loss.

Fig. 2—Photograph nine months after accident. There is a good color match between the nasal skin graft and the surrounding nasal skin.

Full-thickness grafts attach poorly to facial wounds that are infected, whereas split-thickness skin grafts will attach more often. However, split-skin grafts taken from the abdomen, hip or thigh area match the facial skin poorly and appear as a conspicuous patch. After the wound has been healed by use of a thin graft, this conspicuous graft can later be removed and a thicker graft of better color match applied. This would then be applied on a freshly excised area and a good acceptance of the graft would be anticipated.

Ideally, if a thicker graft with a good color match could be applied at the time of initial repair, much time and expense could be saved. In selected cases, this can be done satisfactorily.

In case of loss of skin about the nose, face or ears, a good color match of the graft with the adjacent facial skin can usually be obtained if the graft is taken from an area close to the face. Two convenient donor sites are present: the postauricular sulcus region and the area about the clavicle.

A full-thickness graft can be cut free hand from the postauricular sulcus, and, with care, the graft can be cut even thinner than full thickness. A graft as large as 2.5 × 3.5 cm. can be taken from behind the ear and the defect closed primarily with sutures. A skin graft can be taken from the area below the clavicle, either as a full-thickness graft with primary suture closure of the wound, or as a thick split-thickness graft taken with a mechanical dermatome.*

If the area of skin loss is relatively small (3 × 4 cm. or less) and, more important, if the wound is clean and of recent origin, a full-thickness graft may be employed as an emergency but definitive procedure. The wound should be thoroughly cleansed, tissue shreds debrided, and hemostasis obtained before application of the graft. If the general condition of the patient is not satisfactory, grafting should be deferred; but since this can be done

Here's what you do to get samples of the

anticostive* hematinic

Think small. If you save one person from hunger, you work a miracle. Give to CARE, New York 10016

under local anesthesia, it often can be employed in rather seriously injured individuals.

A pattern is obtained of the skin defect which needs graft coverage. This pattern is used for cutting the correct size graft (clavicular or postauricular). Following excision of the graft and careful removal of any fat along its raw surface (graft should be trimmed as thin as possible with sharp iris scissors), it is sutured over the defect using 5-0 silk sutures. The sutures are left long and are used to tie a bolus type dressing in place over the graft. This dressing will provide immobilization of the graft for the first five to seven days of healing.

In selected cases, application of a well-matched full-thickness skin graft can be applied to areas of facial skin loss as an emergency procedure. The author has observed attachment of the graft to be satisfactory and has found that the definitive graft application has saved considerable time and expense for the patient.

A New Technique for Study of Cerebral Circulation*

THE BRAIN is unique in that it is supplied with blood by at least four arteries and drained by at least two veins, and is enclosed in a box of hard and soft tissue supplied and drained by the same vessels. These characteristics make the measurement of cerebral blood flow extremely difficult. Techniques applicable to other organs are not suitable for the study of the cerebral circulation. Older methods, such as the nitrous-oxide technique of Kety and Schmidt and its variations, measure cerebral blood flow only through the brain as a whole. In addition, these methods are uncomfortable for the subject and require punctures of arterial vessels and the jugular vein. Certain newly developed techniques for the measurement of regional cerebral blood flow require catheterization of the internal carotid artery, which may be dangerous, particularly to patients with cerebrovascular disease.

The use of the scintillation camera, or "gamma camera," for the study of the cerebral circulation, as reported by Loken and associates, is a new technical approach based on well-known theories. Of the methods these investigators use for distributing a radioactive indicator to the brain, the one in which 133-xenon is inhaled by the subject is of greatest interest, because of the relative comfort to the subject and potential freedom from complications.

In theory, the gamma camera could be used to measure intracranial blood flow in two ways. The appearance and disappearance of an indicator in two locations in an artery, such as the middle cerebral artery, could be recorded and blood flow through the artery determined. Alternatively, the appearance and disappearance of an indicator in an area of brain relatively free of arterial and venous vessels could be recorded, and blood flow through a volume of brain tissue determined. For either type of measurement, the resolution of the detector must be very high, both in space and in time. If Loken and colleagues are able to obtain pictures of isotope distribution in the brain at intervals approaching one second, as they state, resolution in time is approaching adequacy; however, as can be seen in their photographs, resolution in space is far from being adequate for quantitation.

Some question the need for a quantitative measure of cerebral blood flow for clinical practice. Certainly the cerebral circulation can be studied qualitatively very well by angiography. But quantitative measurements of cerebral blood flow are valuable in physiologic

*Loken, M. K., Pierce, Robert, Resch, Joseph, Lassen, Niels, and Ingvar, David: Regional Circulation in the Brain Using a Scintillation (Anger) Camera. Minnesota Med 50:497, 1967.

studies in humans and animals and may have considerable potential application in studies of drugs and other types of treatment of cerebrovascular disease. Quantitative measurements also may prove to be valuable in diagnosis, such as in differentiating ischemic cerebrovascular disease from hemorrhagic cerebrovascular disease and tumors. And perhaps by safe quantitative techniques the stroke-prone person can be distinguished from others not as likely to develop a cerebral infarct.

Older methods for the study of the cerebral circulation, although valuable for investigations of small numbers of subjects, will not have wide clinical application because of difficulties of technique. Whether or not newer methods, such as those proposed by Loken and co-workers, will be suitable for clinical use will depend upon whether or not these techniques can be developed to provide more information, or enough information more safely, than angiography.

Arthur G. Waltz, M.D.

Pointing in the Right Direction

ADHERENTS OF the basic medical sciences have generally ridiculed theories of behavior because they seemed to be without scientific validation. Dr. Buckley's article,* one hopes, is only one of many forthcoming papers laying the foundations of the neurophysiology of behavior. Some day, even the purest of purists will comprehend the correlations between brain and behavior and accept psychology as an important variable in all studies of function and disease. Neurophysiologic ground rules are basic, imperative. Dr. Buckley "points us in the right direction," a direction leading to a better understanding and correlation of scientific data which may set aside for always the dualistic theory of mental function. One can only feel a deep sense of humility in the face of man's ignorance of self—and admiration for his zeal for scientific knowledge to find a better place in the sun.

The Editor's Soliloquy

Anima Sans Sexus

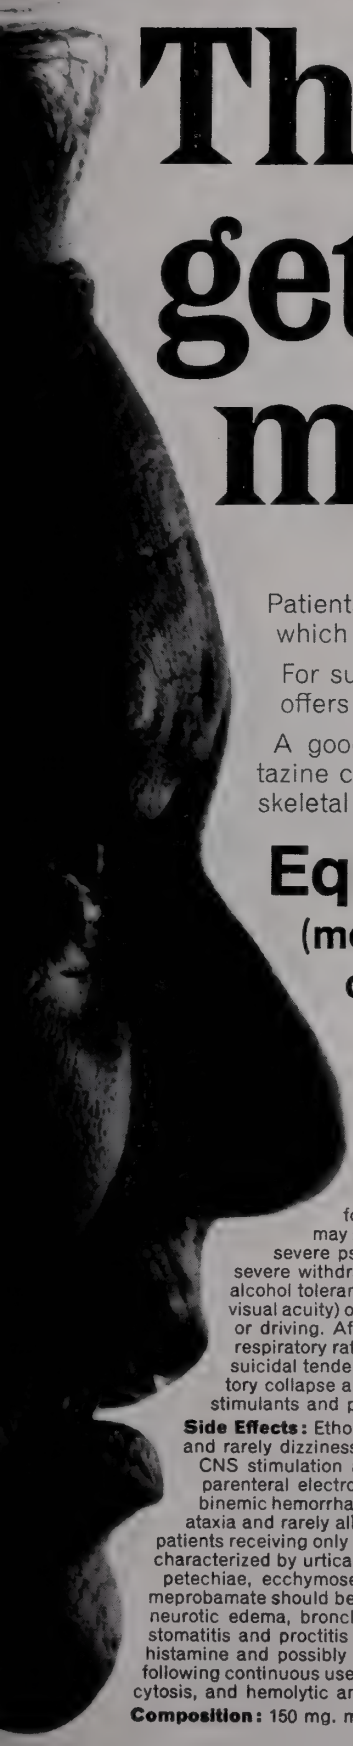
After serving its master faithfully and obediently for years and across two continents: during calm and storm, rain and shine, through sparse or congested traffic, in city, suburb and country, it suddenly rebelled! Heading for the Emergency Ward at the hospital among the hectic permutations and combinations of the crawling, downtown rush-hour exodus, my car horn abdicated—abruptly renouncing all responsibility to remain silent. Scorning timid pianissimo and irresolute staccato, it blared forth sostenuto and fortissimo—with all the authoritative dignity of a Mercedes 250SE Cabriolet. Nor would it cease!

Tapping, pulling, jerking, twisting, banging and kicking at the horn wheel and its contiguous structures were all ridiculously and humiliatingly futile. To add insult to injury, the impudent gremlin within remained relentlessly immune to cajolery and impervious to invectives.

The driver ahead beckoned angrily for me to proceed around and pass him —if I was so all-fired anxious. As I hastened to do so in frantic search of a haven—where I might get relief and be again reduced to the status of anonymity, the oncoming traffic yielded me an ever-widening safety margin for fear of being mowed down—as if a sheer lunatic had been precipitated out of nowhere right into their confounded midst. Faces of bystanders registered a gambit of mixed emotions: from amusement and contempt to defiance, outrage, and even horrified suspicion that I might be harboring an invisible dying emergency or hiding a corpse out of sight on the floor of my car. For certainly I was the only visible occupant in an imposing-looking car that would not be expected to go on a spontaneous rampage—like some of the contraptions wired together by half a dozen teen-age boys.

In spite of—maybe because of—my mortifying predicament, spectators' visages spoke louder than words; my fecund imagination translated their facial expressions into: What's your trouble? Who do you think you are? What's the hurry, man? Think you own the whole street, wise guy? Where's the fire?

Was I perchance rehearsing for a Keystone Comedy film sequence, they must have wondered. Or might I be pursuing a marauding bandit or an eloping daughter? Or had I maybe lost my place in a blithe wedding procession —or a solemn funeral cortege?



I know of nothing better to humble a man's spirit and relegate him to his proper niche in the cosmic scheme of things than a horn in revolt!

Carl O. Rice, M.D.

Old Doc Hess says: We desire the tranquility of sleep and sweet dreams. Why should we fear the eternal sleep?—C.O.R.

Laugh and the world laughs with you; think and you will almost die from lonesomeness.—Christian Action

This pain is getting on my nerves.

Patients in pain often experience concomitant anxiety and tension, which may add to the burden of pain.

For such patients, you may want to prescribe a preparation that offers more than simple analgesia.

A good choice is often EQUAGESIC® (meprobamate and ethoheptazine citrate with aspirin). It helps relieve pain. And anxiety. And skeletal muscle spasm as related to pain or anxiety and tension.

Equagesic® TABLETS

(meprobamate and ethoheptazine citrate with aspirin)

Wyeth®

Contraindications: History of sensitivity or severe intolerance to aspirin or meprobamate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore it should be used in pregnant patients or women of child-bearing age only when the physician judges its use essential to the patient's welfare.

Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate may result in dependence or habituation in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics. Withdraw gradually after prolonged high dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, caution patients against operating machinery or driving. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with immediate gastric lavage and appropriate supportive therapy (CNS stimulants and pressor amines as indicated).

Side Effects: Ethoheptazine and aspirin may occasionally cause nausea, vomiting, epigastric distress, and rarely dizziness. Overdosage may result in CNS depression (drowsiness and lightheadedness) or CNS stimulation and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]). Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically such as with epinephrine, antihistamine and possibly hydrocortisone. A few cases of leucopenia, usually transient, have been reported following continuous use. Rarely, cases of aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported; almost always, in the presence of known toxic agents.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Hip Disability

QUESTION: Disability rating continues to pose problems for the medical profession and, accordingly, certain pertinent questions can be raised under the heading of "hip disability." What is an equitable disability rating for a male patient with loss of the leg at the level of amputation with a normal hip joint? What rating for a man with an artificial hip joint?

ANSWER: The following case, summarized from time of injury through Industrial Commission settlement, may help in the evaluation of similar cases as well as of various other hip conditions requiring disability rating.

A 49-year-old mechanic fell on August 30, 1963, and injured his right hip. Though it was painful, he continued working for two days before seeing a doctor. An x-ray study of the hip was read as negative. Although he was never free of symptoms, he continued to work. In the fall of 1964, his pain became increasingly severe and was accompanied by snapping of the hip on motion. X-ray studies then revealed an avascular necrosis with collapse of the femoral head. He was hospitalized for a period of skeletal traction, then operated upon, and a femoral head prosthesis was inserted.

The outcome, a year later, would be considered the usual result of such a salvage operation. He walked with a cane and had slight pain and some generalized muscle atrophy. There was full extension and 105 degrees of flexion, 10 degrees external and 10 degrees internal rotation with about one-half the normal range of abduction present. The involved extremity was one-half inch shorter than its normal length.

The permanent partial disability rating arrived at in an Industrial Commission hearing was 40 per cent of the lower extremity. By comparison, an arthrodesis of the hip in optimum position would receive a rating of 50 per cent. A hip fracture treated by open reduction and followed by good healing with an average end result would be rated at 15 per cent disability. In instances where shortening occurs, 5 per cent disability is usually considered to be a fair rating for each half inch of shortening.

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

Anxiety and tension often "switch on" a multiplicity of physical complaints.

a tranquilizer with particular usefulness in functional disorders

Tybatran™

(pronounced TYE-buh-tran)

brand of tybamate

Extensive clinical experience, including eleven double-blind studies,[1-11] indicates that Tybatran is an effective agent for the relief of anxiety and tension. It appears to lend itself particularly well to the management of the anxious patient who "somatizes"—whose anxiety and tension find expression in complaints such as headaches,[4,8,10,11] fatigue,[4] insomnia,[2,4,8,9,12] anorexia,[3,8,9] and pruritus.[7]

Two salient features seem to set Tybatran somewhat apart from certain other commonly used tranquilizers.

1. Tybatran often proves more effective than meprobamate and chlordiazepoxide. In one study,[4] severe anxiety responded more effectively to tybamate than to meprobamate; in another,[8] symptom-response superiority of tybamate over chlordiazepoxide was marked at statistically significant levels of confidence.

2. Tybatran appears to be less sedating than other widely used tranquilizers. Side reactions are relatively infrequent; when they do occur, they may take the form of drowsiness, although insomnia, ataxia and other adverse effects have been reported. Nevertheless, Tybatran impresses many clinicians by its comparative lack of undesirable sedative action.[3,6,12,13] (If drowsiness or vertigo is present, activities requiring optimal alertness should be avoided.)

For patients in whom anxiety is manifested in any of a multiplicity of physical complaints, Tybatran deserves a clinical trial. These are the challenging patients, those with recurrent, persistent, ever-changing symptoms for which there is no clinical or laboratory evidence of organic disease.

Usual adult dose: one or two 250 mg. capsules 3 or 4 times daily. Adjust to suit individual requirements.

A·H·ROBINS

Prescribing Information

Dosage and administration. The suggested adult dose of Tybatran (tybamate) is one or two 250 mg. capsules three or four times daily. Dosage should be adjusted to suit individual requirements. While clinical experience with Tybatran (tybamate) in children has been very limited to date, the recommended daily dosage for children 6 to 12 years old is 20 to 35 mg./kg. body weight, in three or four equally divided doses. Dosage should be adjusted to suit individual requirements. Until further clinical experience is obtained, administration of Tybatran (tybamate) to children under 6 years of age is not recommended. Daily doses larger than 3000 mg. are not recommended, although in a few instances doses in excess of this figure have been administered. Tybatran (tybamate) is also available in 350 mg. capsules, for convenience in dosage adjustment, e.g., one capsule three times daily and two at bedtime.

Contraindications. Tybatran (tybamate) should not be administered to patients known to be hypersensitive to the drug. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings. Simultaneous administration to psychotic patients of tybamate with phenothiazines and other central nervous system depressants has in a few instances been associated with the occurrence of grand mal or petit mal seizures. Seizures have been reported with administration of phenothiazines alone, but not with administration of tybamate alone; nevertheless, tybamate should be used cautiously in individuals who are receiving other central nervous system depressants or have a history of convulsive seizures. Also, it should be borne in mind that simultaneous administration of tybamate with alcohol or with other psychotropic agents, particularly phenothiazines or monoamine oxidase inhibitors, which are known to potentiate the action of other drugs, may result in additive actions.

Precautions. There has been no evidence to date of the development of habituation or addiction. Investigators have not observed excessive self-medication or any withdrawal symptoms with use of Tybatran (tybamate), but the latter should be kept in mind with cessation of the drug after prolonged use. Because of the occurrence of

Prescribing information continued on next page.

(pronounced TYE-buh-tran)

Tybatran™

brand of tybamate

a tranquilizer with particular usefulness in functional disorders

Prescribing information continued from preceding page.

withdrawal symptoms or exacerbation of presenting symptoms upon rapid withdrawal of other agents of this type, abrupt withdrawal of Tybatran (tybamate) should be avoided. Tybamate, like other psychotherapeutic agents, should be used with caution in addiction-prone individuals. Should symptoms of hypersensitivity occur, administration should be discontinued at once and appropriate symptomatic treatment initiated. Operation of motor vehicles or machinery or other activities requiring optimal mental alertness should be avoided if drowsiness or vertigo is present. As with any new drug, Tybatran (tybamate), should be used with caution in patients with a history of drug allergies, blood dyscrasias, and hepatic or renal disease; and prolonged and/or high doses of tybamate should be accompanied by periodic measurements of hepatic, hematopoietic, and renal function.

Adverse reactions. While these have only rarely required discontinuation of the drug, the most frequently encountered reactions have included drowsiness, dizziness, nausea, insomnia, euphoria. The drug was discontinued in one child because of a possible drug-induced urticaria, and skin rash and pruritus have been encountered in a few other patients. In a few patients, effects suggesting excessive stimulation such as hyperactivity, fidgetiness, flushing, and tachycardia have been encountered. Other reported side effects recorded only a few times to date have included ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients to whom tybamate (up to 6000 mg. daily), phenothiazines, and other psychotropic agents were administered simultaneously. Convulsive seizures have not been reported with the use of tybamate alone.

Until clinical experience has accumulated with this drug, inasmuch as tybamate is related to meprobamate, the physician should be cautious about the possibility of rare, serious adverse reactions such as may be encountered with the latter drug. Should excessive doses of tybamate be ingested, it is recommended that any drug remaining in the stomach be removed and symptomatic therapy, including central stimulants, be used as necessary.

Supply. Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

Juvenile Diabetic

THE RETROGRADE pyelogram pictured below is that of a 35-year-old female juvenile diabetic. Over the past 20 years she has been hospitalized nine times for recurrent pyelonephritis. E. coli, Proteus, and Aerobacter have on different occasions been cultured from her urine.

For three days prior to the current admission she had experienced left flank pain of a colicky nature radiating into the groin and accompanied by vomiting, fever, and dysuria.

On admission her temperature was 102°, B.P. 108/60, pulse 124, and respirations 24. Urinalysis revealed 3+ glucosuria, acetone positive, with 125 wbc. and 35 RBC/hpf. Her BUN was 21 mg%, blood sugar 293 mg%, and CO_2 17.5 meq/1.

The retrograde study antedates the current admission by several months. The right kidney is relatively normal. You will notice that the normal cup-shaped appearance of the minor calyces on the left is compromised. The smooth outline of the calyceal fornices is, however, preserved and the renal pelvis and the proximal ureter appear normal.

What is your diagnosis? (See next page.)

Fig. 1—Flask-shaped defects are demonstrated (arrows) within the papilla.

Diagnosis: Renal Papillary Necrosis

The basic pathology of renal papillary necrosis involves ischemic infarction of the renal papilla. The renal papilla is particularly susceptible to vascular compromise because of its blood supply consisting of: (1) vessels from the glomeruli which seldom anastomose and (2) small spiral arteries from the adventitia of the minor calyces that penetrate the papilla. Compression of these vessels from pressure or edema may result in necrosis.

Etiologic factors include:

1. diabetes mellitus
2. chronic pyelonephritis
3. phenacetin abuse
4. urinary tract obstruction
5. sickle cell disease or trait
6. renal vein thrombosis
7. shock

Radiologic examination is the only reliable method of diagnosis of renal papillary necrosis during life unless papillary fragments are passed or the kidney is biopsied or excised.

Many of the early radiographic findings in renal papillary necrosis are nonspecific; local reduction of function, irregular papilla, and dilatation of fornices. These changes may be seen in common pyelonephritis and in renal tuberculosis.

The classification of renal papillary necrosis used today was recorded in 1948 by Gunther, who divided it into two types: the medullary and papillary forms based on the extent of necrosis. The tip of the papilla only is destroyed in the medullary type with preservation of the calyceal fornix. In the papillary type the entire papilla is involved including the fornix and varying portions of the renal pyramid. In either type the papilla is sequestered, producing on urographic study the characteristic "ring sign." Contrast surrounding the less dense necrotic papilla within the calyx creates this "ring sign." Later in the course of renal papillary necrosis the necrotic papilla is sloughed away or resorbed, leaving a flask-shaped defect in the papilla, as in the presented case, or a "clubbed" calyx. If the necrotic papilla remains in the calyx, it will usually calcify and appear on radiographic examination as a concretion with a radiolucent nidus.

In 1877 von Friedreich first described renal papillary necrosis in an elderly man with prostatic hypertrophy and chronic urinary tract obstruction. He ascribed the necrosis to kinking of the papillary vessels interfering with the blood supply, and he implied that flattening of the papillary regions in hydronephrosis could in certain cases be due to papillary necrosis, and that the papillary fragments voided might allow antemortem diagnosis.

As late as the mid-1950s renal papillary necrosis was generally regarded as a complication of diabetes mellitus or chronic urinary tract obstruction frequently associated with infection. It was held to be a highly fatal disease. The glomerulosclerosis and arteriosclerosis of the diabetic Kimmelstiel-Wilson kidney or the elevated intrapelvic pressure of obstruction combined with infection infarct the papilla. The outstanding clinical characteristic of this fatal type of renal papillary necrosis is a sudden marked worsening of the patient's general condition, with colic, hematuria, fever, and uremia.

In recent years a new type of renal papillary necrosis has emerged with a better prognosis. Chronic phenacetin ingestion is the cause. In the two

largest series of renal papillary necrosis thus far reported, totaling 258 cases, the predominant etiologic factor was phenacetin abuse. A minimum of one gram daily for at least one year or a cumulative dose of approximately one kilogram is felt to be necessary before the nephrotoxic effect of phenacetin results in interstitial nephritis and renal papillary necrosis.

Phenacetin is found in many of the commonly used and perhaps abused proprietary analgesics: Anacin, Anahist, APC tablets, aspirin compound, Bromo-quinine decongestant, Coricidin, Empirin compound, and Vick's cold tablets.

A very frequent association of migraine-like headaches and abuse of phenacetin is reported by the Scandinavian authors.

The caffeine, codeine, and barbiturates compounded with phenacetin contribute to the problem of addiction. Phenacetin-induced renal papillary necrosis is usually chronic and may be partially reversible after withdrawal of the medication. For this reason a history of phenacetin abuse can be an important although often occult bit of information.

Sickle cell disease and trait are also known to cause renal papillary necrosis. Conditions in the renal papilla are ideal for sickling. The oxygen tension within the kidney is known to diminish from the cortex to the papilla, and the interstitial fluid of the papilla is of high osmolarity. Papillary infarction is the end result of this type of vascular insult.

Renal papillary necrosis is most often a disease of middle age but is seen in infants and the aged. It may be acute or chronic. It is usually bilateral, but may be unilateral. Seven females are affected for every male. The prognosis depends on the primary cause and complications and the efficacy with which these are treated.

She doesn't feel she "suffers" from hypertension

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either disease *or* therapy

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure[1]...at times to levels *below* those attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

BUTISOL® (butabarbital) 30 mg. (½ gr.)†; Hydrochlorothiazide 25 mg. (⅜ gr.); Reserpine 0.1 mg.

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

Butiserpazide®-50

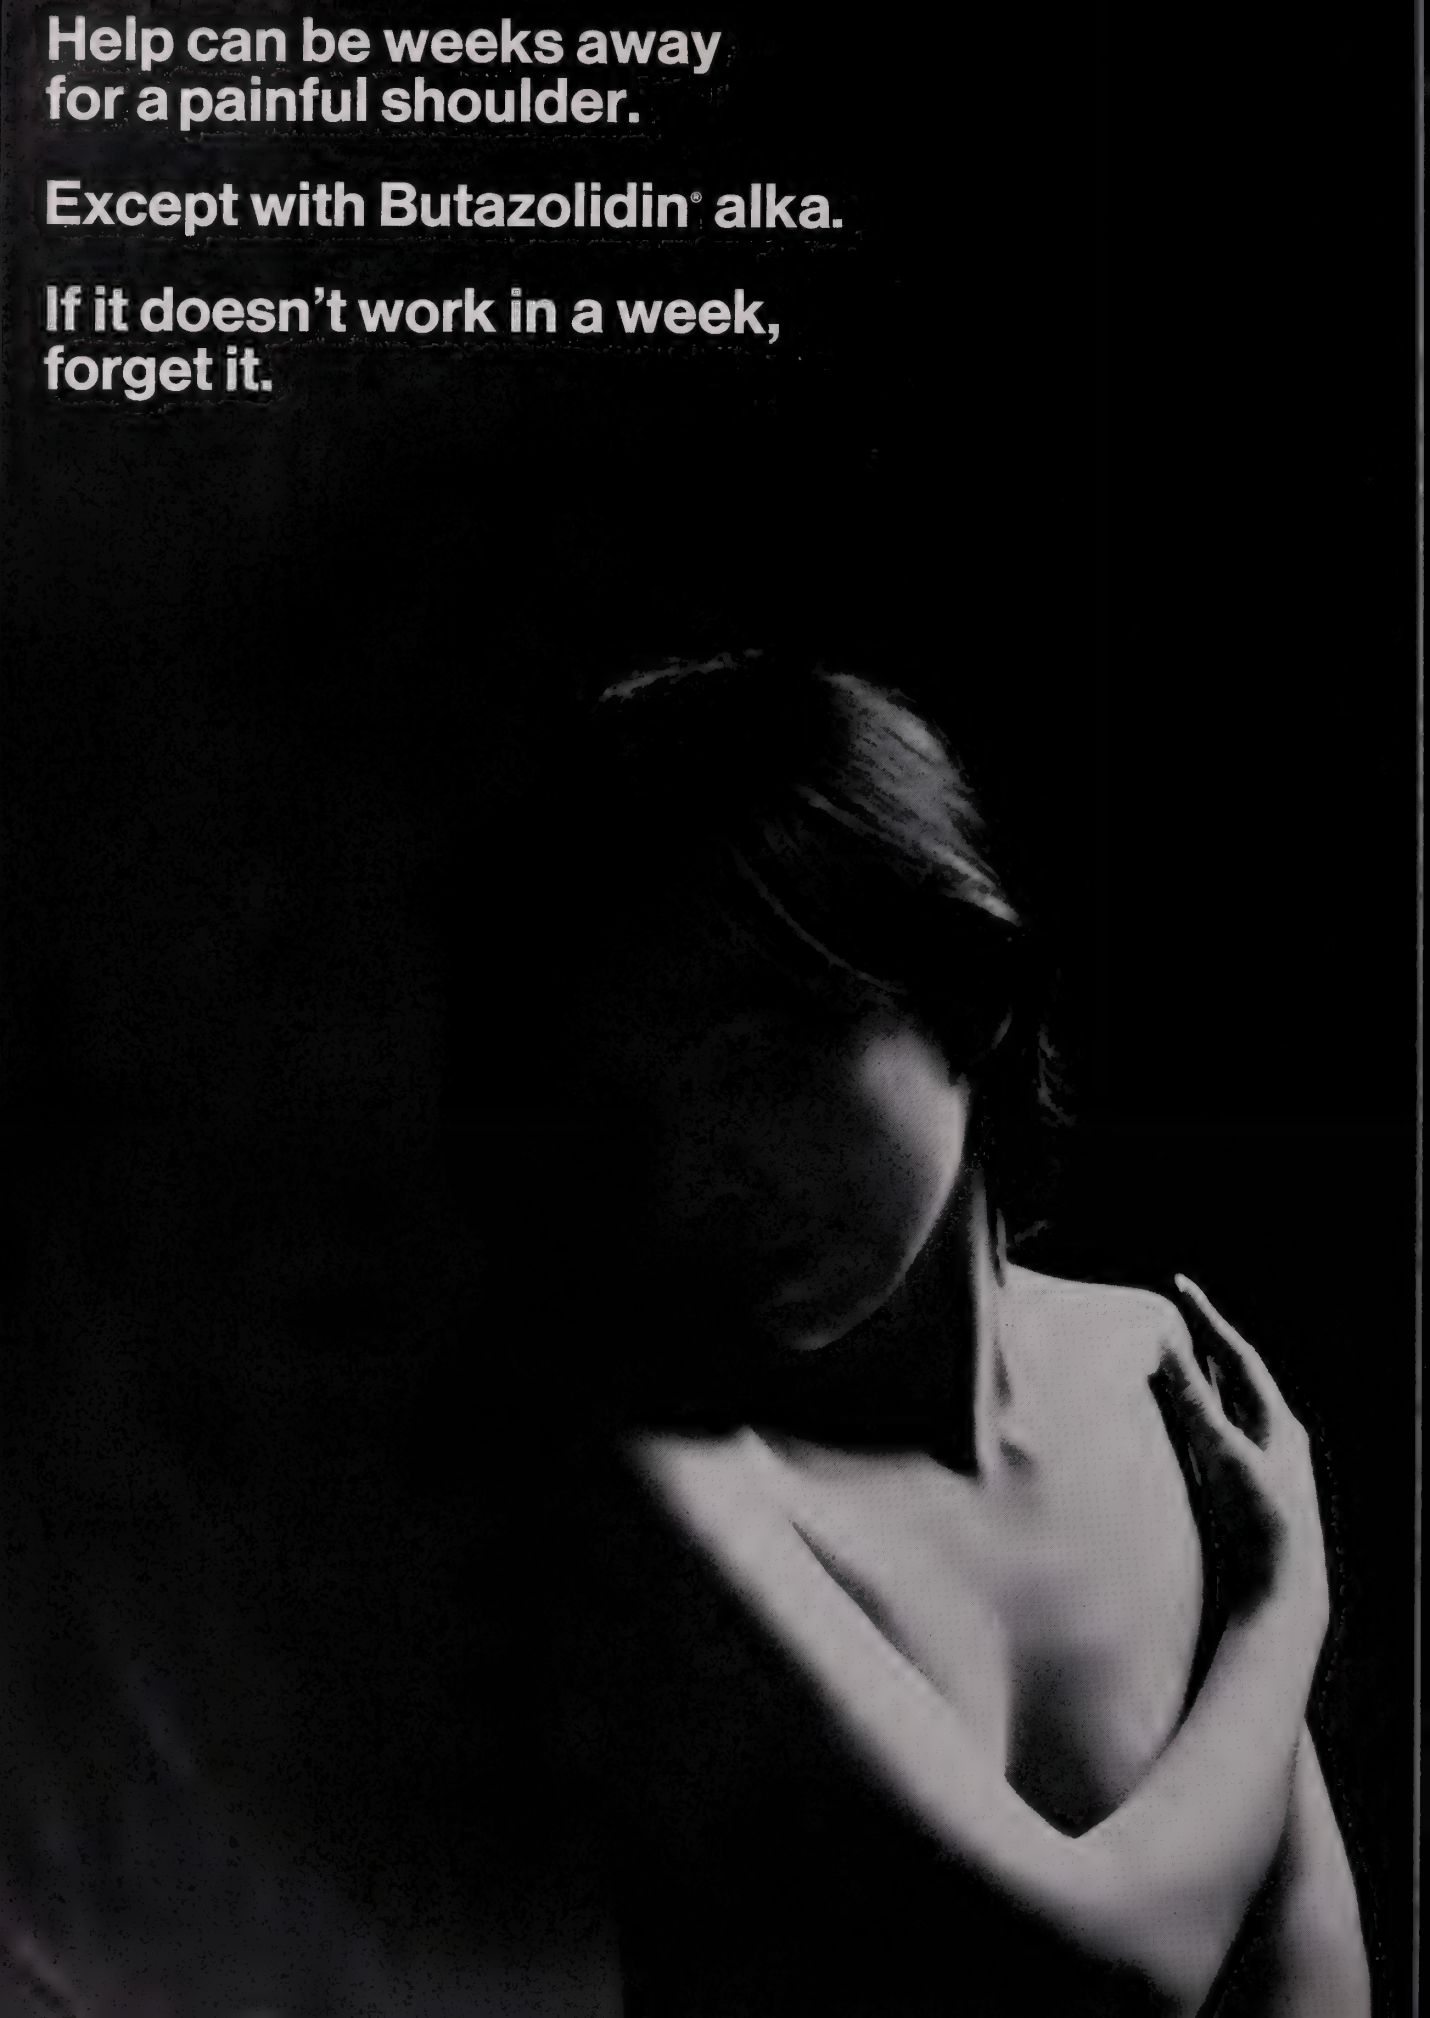
Prestabs®* Tablets

BUTISOL® (butabarbital) 30 mg. (½ gr.)†; Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

*15 mg. of **Butisol** (butabarbital), plus the other ingredients, in outer layer; 15 mg. of **Butisol** (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyperuricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †**Warning:** May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: Penna. M. J.: 67:35, 1964. 2. Coodley, E. L.: Curr. Ther. Res. 4:460, 1962.



McNEIL

McNEIL LABORATORIES, INC., FORT WASHINGTON, PA.

Help can be weeks away
for a painful shoulder.

Except with Butazolidin® alka.

If it doesn't work in a week,
forget it.

But don't forget this about Butazolidin alka

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of Butazolidin alka are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make regular blood counts. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Mild drug rashes frequently subside with reduction of dosage. However, rash accompanied by fever or other systemic reactions usually requires withholding medication. Purpuric rash has also been reported. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Painful Shoulder: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: one week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

Trauma Conference

Osteochondral Fractures of the Talus

(Osteochondritis Dissecans)

OSTEOCHONDRAL FRACTURE of the talus is not a common disease entity. No large series of cases has been recorded. This may account for the lack of consensus regarding therapy. Berndt and Harty in 1959 presented an excellent review of the literature with a detailed analysis of cases including experimental studies and arrived at two conclusions. First, that trauma is almost always the etiologic agent. Second, that surgical removal of the fragment gives the highest percentage of good results in symptomatic patients.

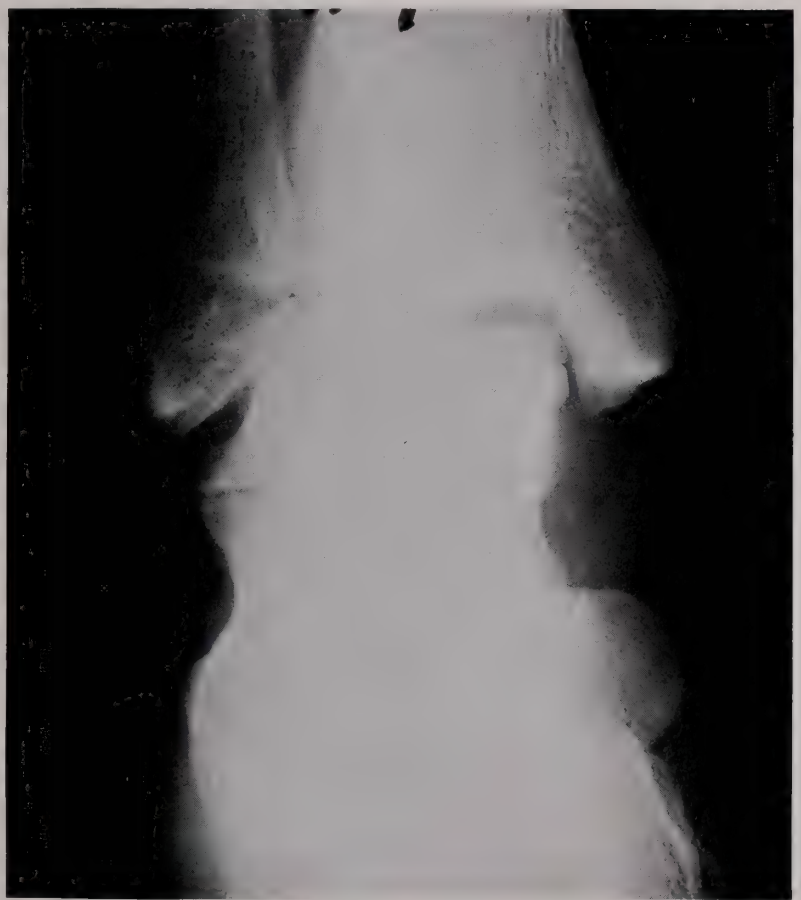

Fig. 1—AP ankle. Note radiolucent line surrounding detached fragment along the superior articular surface of the talus medially.

They also pointed out that the majority of these patients are asymptomatic.

This study is an analysis of ten cases of osteochondral fracture of the talus seen at the St. Louis Park Medical Center, Minneapolis, Minnesota, from 1953 to 1965. Six out of 10 patients gave a definite history of trauma. Four patients came in because of chronic recurrent pain, aching, and swelling of the ankle with no antecedent history of injury. The age range was from seven to 72 years. On x-rays of the ankle, seven out of 10 showed a defect in the lateral aspect of the talus superiorly. The duration of signs and symptoms ranged from one to 63 years. Followup was made in nine patients varying from one to 12 years. These patients were treated conservatively in various ways from a short-leg walking cast to crutches, Ace bandages, rest, elevation, and no treatment at all.

The typical x-ray finding is one of a zone of radiolucency or a depressed fragment either medially or laterally on the superior articular surface. Sometimes a clear zone of radiolucency is seen around a sclerotic fragment. A secondary degenerative arthritis can be found either at the medial or lateral side of the ankle joint in cases where there is a long history of signs and symptoms. Soft tissue swelling around the ankle is seen in cases where acute trauma preceded the onset of symptoms.

The detailed analysis of every patient seen at the St. Louis Park Medical Center is outlined in Table 1.

Fig. 2—Oblique ankle. Better demonstration of detached but undisplaced fragment.

Case Reports

Case 1:

This 13-year-old girl was seen at the St. Louis Park Medical Center in 1956 because of occasional pain, swelling, and restricted motion of the ankle. The patient denied any history of trauma at any time in the past. Pertinent orthopedic findings on physical examination were limited to slight swelling with minimal discomfort on extreme range of motion. X-rays taken October 27, 1956, showed a typical radiolucent zone on the medial aspect of the talus, and

TABLE I
Osteochrondritis Dissecans (Osteochondral Fracture of the Talus)
Summary of Results

Patient	Patients' Age	S & S	Treatment	Followup	Results
1. P.A.	13 years	Occasional pain, swelling, & restricted motion. No history of trauma.	Short leg cast for eight weeks.	Ten years	Asymptomatic.
2. A.J.	10 years	Pain & swelling aggravated by running, jumping, etc. Twisted left ankle.	Rest, crutches for two weeks.	One and one-half years	Still has pain & recurrent swelling on heavy activities.
3. E.F.	63 years	Recurrent aching & swelling of ankle of several years duration. No history of trauma.	Rest, Colchicine & Benemid for his gout appeared to help.	Five years	Asymptomatic.
4. S.T.	26 years	Twisted left ankle, pain & swelling.	Short leg cast, four weeks.	Nine years	Asymptomatic.
5. D.B.	12 years	Twisted left ankle, pain & swelling.	Compression bandage, seven days.	None	Not known.
6. B.C.	72 years	Injured foot & ankle at 9 years of age. Progressive pain & swelling with marked limitation of motion.	None.	Sixty-three years	Pain, swelling, advanced degenerative arthritis of ankle joint.
7. M.S.	62 years	Twisted left ankle. Pain & swelling, fracture lateral maleolus. Osteochondral fracture, medial talus.	Short leg cast for six weeks.	Two years	Occasional pain & swelling.
8. E.K.	26 years	No history of trauma. Pain lateral ankle area. Minimal swelling.	Heat, ankle support, aspirin.	One and one-half years	Asymptomatic.
9. M.L.	9 years	Fall from a merry-go-round. Pain & swelling. Undisplaced fracture of fibula also.	Cast for ten weeks.	Six years	Fracture healed. Occasional pain & swelling aggravated by excessive use of foot and ankle.
10. H.R.	36 years	Injured ankle playing baseball in grade school. Chronic aching & giving way of ankle when involved in running, baseball, etc.	None.	Five years	Symptomatic only when running up stairs & sliding. Occasionally aches. X-ray early arthritis medial side of ankle joint.

a diagnosis of osteochondritis dissecans was made (Figure 1). The patient was treated for eight weeks in a short leg cast. Followup x-ray studies in 1960 and 1965 again showed the detached but undisplaced fragment on the medial side of the talus in almost identical position. The osteochondral fracture had not united in ten years. In 1960 the patient was only slightly symptomatic when involved in very vigorous activities like running and jumping. Ten years after the initial x-ray the patient is completely asymptomatic.

Case 2:

A 27-year-old white male sustained an Achilles tendon rupture May 28, 1965, while playing baseball. X-rays taken of the ankle showed an osteochrondral fracture at the medial end of the talus (Figure 2.) The patient states that for several years he had aching pain and a "giving-out-sensation" in the ankle following a football or baseball game. He denies any history of trauma just before onset of symptoms.

A primary repair of the Achilles tendon was done.

The right leg was placed in a long leg cast for six weeks and a short leg cast for four weeks.

On last examination, July 21, 1956, the osteochondral fracture appears unchanged. The patient is now asymptomatic even on prolonged standing or running. The ruptured Achilles tendon has healed without complication.

Fig. 3—(Case 2) (left) radiolucent defect appears to lie below the articular surface. (Right) radiolucent defect involves medial superior corner of articular surface. Small bone fragment is seen within the radiolucent zone.

From this study it appears that only two patients out of ten were definitely symptomatic. In these two patients the symptoms were probably due to secondary degenerative arthritis. Three patients were symptomatic only on excessive use of the foot or ankle, as in running, prolonged walking, or jumping. The other patients were completely asymptomatic. From this small number of cases, it would appear that many of these patients do not have symptoms. It would indicate, however, that if the patient is symptomatic, a more vigorous approach to the problem is needed. This is preferred to merely observing the patient in order to prevent development of a secondary degenerative arthritis. It is recommended that these patients be placed in a cast for three months, allowing sufficient time for the osteochondral fracture to unite, especially when a history of trauma is given. If, after three

months, the patients continue to have symptoms, the removal of the fragment is indicated as recommended by Berndt and Harty in their series.

Audio-Analgesia

Music to ease pain has been used for some time without any great scientific concentration on its possibilities. Today, a greater amount of attention is being focused on this particular area. Experiments are currently under way in which music and special static sound effects, known as "white sound," are played to a patient during certain types of dental or minor surgery. Preliminary results indicate that these combinations of relaxing music and somewhat disturbing white sound crowd the thalamus and cerebral cortex with a high level of sensory input and seem to reduce the sensation and recognition of pain.*

Into the Hold

The police played a tremendously important part in my life as an ambulance surgeon. I discovered when I started duty that not only could I count on the faithful drivers to lift and carry for me, but that, the minute I mounted the tailboard, I acquired the rank of Sergeant of Police, and could command as many roundsmen as I needed. I remember on one occasion finding myself on a rope ladder—probably a policeman just below me, and another one just above. It had not occurred to me that I might fall off, and I was wondering why it was necessary to have those two policemen, and whether the ladder could possibly hold all three of us. Undoubtedly they decided when they saw me arrive with the ambulance that they would not take the chance of my falling off on that hazardous little trip down into the bowels of the ship. In this case had I hesitated and looked down into the dizzy depths of the hold, I might easily have become panic-stricken. And so in solemn though vertical procession, we three reached the bottom safely, where I found that a sailor had fallen into the hold. He had landed on his feet, fracturing some of the small bones. I put his feet into splints and prepared him as carefully as I could for his removal to the hospital, and we retraced our steps up the swinging ladder, a policeman above me and one below, "just in case."*

Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.

SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.

ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q. 4 h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA **SINUTAB®** FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

Tumor Conference

Thymoma?

TUMORS OF THE thymus catch more than average interest since the role of the thymus immunology is just recently coming to light. Even more interesting is the association of thymic tumors with myasthenia gravis. This case illustrates a third frequent source of interest—a tumor, arising in the area of the thymus, which has no other source of origin, but is not a thymoma in the strict sense. The following case also illustrates some of the more sinister elements of thymic tumors. Thymic tumors start in the anterior mediastinum and with continued invasive growth encroach on neighboring structures, causing pain, dyspnea, or signs of superior vena cava obstruction. Nonresectable malignant thymomas may remain asymptomatic for a long time,[1] not being suspected until a chest film shows a mass in the anterior upper mediastinum.

Case Report

A 23-year-old quadriplegic was transferred to the Minneapolis Veterans Hospital on 11/23/65 for evaluation of a right upper chest mass, possibly a traumatic aneurysm of the aortic arch.

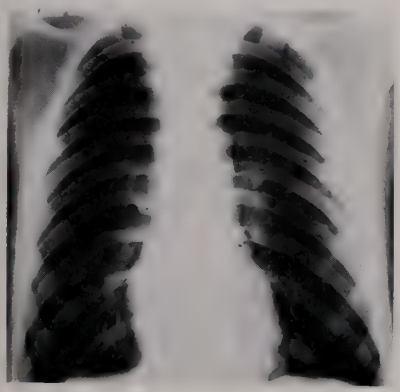

Fig. 1—A chest x-ray taken about one year prior to admission. There were several old granulomata present. The slight widening of the upper mediastinum was not appreciated at that time.

Fig. 2—A chest x-ray taken just before admission showing the huge mass in the right side of the chest.

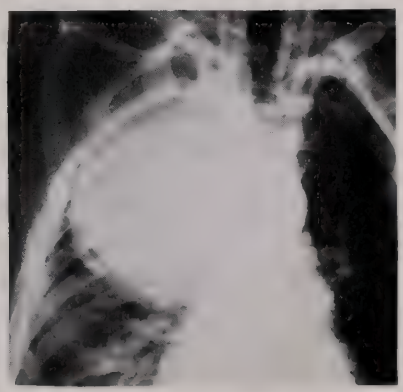

Fig. 3—An arteriogram showing the mass adjacent to, but not involving the aortic arch.

History

The patient had been well before his enlistment in the Army. In 1960, while running an obstacle course, he fractured and dislocated the cervical spine, resulting in quadriplegia. Since 1960 the patient had been treated as an out-patient for upper respiratory and urinary tract infections. Periodic chest x-rays were negative up to one year before admission (Figure 1). However, on a routine posterior-anterior chest x-ray in October, 1965, a mass was noted in the area of the right upper lobe. The patient was asymptomatic. A repeat x-ray in November, 1965, showed a marked increase in the size of the lesion (Figure 2). The patient then began complaining of dyspnea and right upper chest pain when sitting.

Physical Examination

This 23-year-old quadriplegic was in no acute distress. A neurological deficit compatible with a spinal cord transection at the T4 level was present. Blood pressure, pulse and temperature were normal. Arm pressures were equal. The chest expanded well. Dullness and diminished breath sounds over the right upper chest were noted. There were no signs of superior caval obstruction.

Chest x-ray, posterior-anterior and lateral, revealed a large mass, contiguous with the mediastinum, occupying the right upper chest. A retrograde arteriogram showed a normal outline of the central arterial tree with some displacement (Figure 3). Tumor vessels were not demonstrated and an esophagram failed to show esophageal displacement.

Operation

On November 29, 1965, a right posterolateral thoracotomy was performed. A large tumor was found, filling the right chest cavity, compressing the right upper lobe, and extending into the anterior mediastinum. There was an associated atelectasis of the right upper lobe. The great vessels could be dissected from the adjacent tumor. The tumor was excised as widely as possible, but central margins were meager.

Progress

Postoperatively, the patient needed artificial respiration for four days, due to a temporary phrenic nerve palsy. At the time of discharge, the right lung had satisfactorily expanded. The patient was asymptomatic, up in a wheel chair as he had been preoperatively. A pathology report revealed undifferentiated sarcoma, most likely arising in the thymus gland.

For the convenience of the patient's family, follow-up was transferred to his hometown Veteran's Hospital. Eight months later, he was admitted there with hemoptysis and x-ray evidence of local recurrence. He was treated with x-ray (2000 r. tumor dose) and methotrexate, which gave almost one year of palliation. He died 20 months postoperatively.

Comment

Nelms and Nicoloff,[2] reviewing mediastinal tumors over 15 years at Minneapolis V. A. Hospital, found 94 tumors, of which 17 were thymic in origin. It is frequently difficult, as in the illustrative case, to be certain that an anterior mediastinal tumor had its origin in the thymus. It is difficult to exclude tumors which arise in the stroma of the gland, such as fibrosarcoma, myxosarcoma, or liposarcoma. There is the controversy over the origin of the cellular elements of thymic parenchyma. The problem is further clouded by primary and secondary neoplasms which commonly involve the lymph nodes of the anterior mediastinum. The anterior mediastinum is a common site for teratomas and for direct extension of primary tumors of the lung. [3,4] Finally, extensive degenerative changes within the tumor may make its identification on a histologic basis difficult or impossible.

Criteria for Diagnosis

Seybold and Claggett[1] have outlined criteria for establishing a tumor of the anterior mediastinum as a thymoma. They emphasize, as does Castleman,[5] that all other sources should be ruled out. In the instance of a large anaplas-

tic, partially necrotic tumor, with distorted anatomic relationships, there can be no real certainty of thymic origin. The usual thymoma is a slow-growing tumor of the thymus, which has arisen from both the epithelial (reticulum) and thymocytic elements of the thymic parenchyma. The relative proportion of these cells varies greatly from tumor to tumor and often from place to place in the same tumor. Typical Hassall's corpuscles are absent in most thymomas.

Morbidity

Thymomas exert their lethal effect by direct extension and invasion. Embolic metastases either by way of blood or lymphatics are rare. These tumors display few histologic features of malignancy such as hyperchromasia, increased nuclear cytoplasmic ratio, and mitotic figures. This is true even of thymomas, which are not resectable because of gross invasion of contiguous structures. Hence, it is frequently the surgeon and not the pathologist who determines whether the tumor is benign or malignant.

Although a lengthy discussion of myasthenia gravis is not warranted by this case, it is interesting to note that there seems to be no definite histologic pattern by which one can distinguish a thymoma in a patient who does or does not have myasthenia gravis. It is also a well accepted fact that the malignancy of thymic tumors has no relationship to the presence or absence of myasthenia gravis.[6] Furthermore, thymoma can occur either before or after the appearance of myasthenia gravis. Of particular and important interest are cases in which myasthenia gravis may develop abruptly during the early postoperative period following the removal of a thymoma. In the illustrative case, the detection of myasthenia gravis in a quadriplegic patient poses real problems.

The association of thymoma and agammaglobulinemia has been one of the motive observations stimulating interest in the role of the thymus in immune processes.[7] This has been reviewed by Good and co-workers.[8]

Management

Management of these tumors presents problems. Because of their malignant potential (10-25%) and involvement of mediastinal contents all thymic tumors *should be explored and resected,* if at all possible, regardless of whether or not the patient has myasthenia gravis. Every effort to eradicate the tumor surgically must be made, because distant metastases are uncommon and even invasive types may be cured. One may resort to grafting the great vessels in removing the tumor.

The question of the usefulness of *chemotherapy and roentgen therapy* alone and/or combined with surgery has not been well answered. Decker[9] in 1935, in reviewing 206 cases of malignant thymomas, came to the pessimistic conclusion that carcinoma of the thymus will be fatal unless the growth can be successfully removed. He did advocate that roentgen therapy be used in cases of "lymphosarcoma of the thymus."

Brody and Legg [10] reported 10 cases of invasive thymoma. Seven were treated solely by x-ray after biopsy; two had irradiation after attempted extirpation. Four of the ten patients survived five years after therapy and two others were alive at one-and-a-half and two years.

Ochsner and Burch[11] reported 20 thymomas treated in various ways.

Twelve were malignant and eight were benign. A total of 15 patients had only partial excision or biopsy of the tumors. Nine patients were treated with roentgen therapy and six with chemotherapy. Of the nine patients treated by irradiation, seven had malignant tumors and two had benign tumors. Three patients, all with malignant tumors, died. Of the six patients treated with nitrogen mustard, three of the five with malignant tumors are well, and two are dead. The longest survival after roentgen therapy and nitrogen mustard is 14 years in a patient with malignant thymoma. From these studies it seems that x-ray may be a useful adjunct to surgery. Since a significant number of thymic tumors are radiosensitive, particularly those with a large lymphoid component, failure to remove the tumor surgically is not hopeless. Irradiation alone or combined with chemotherapy may be of further definitive or palliative benefit, especially when diagnostic reservations are made as to tumor origin and cell type.

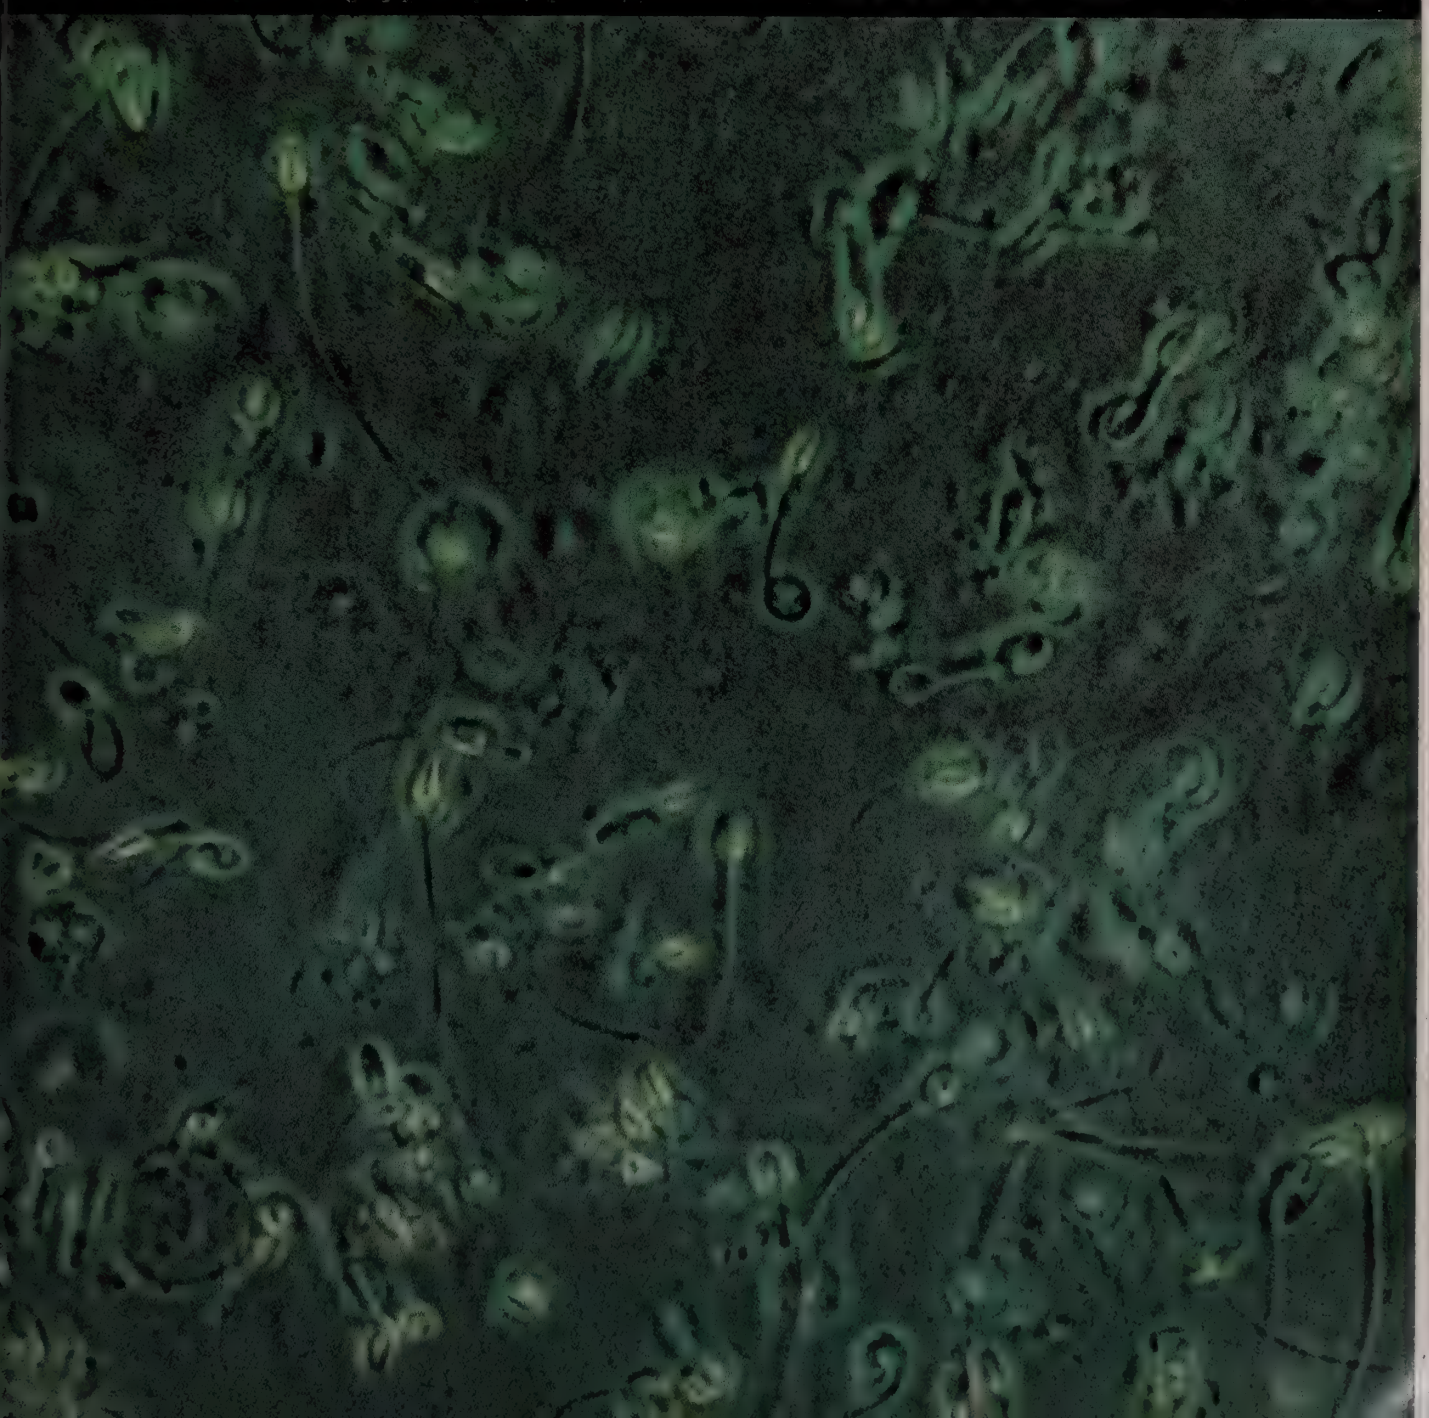
The Patient's Role



The expression "the patient" sounds as if it meant one definite person, someone who simultaneously is ill and wants help, to whom the doctor is called, and with whom the doctor deals. Usually, however, "the patient" was more than one person (often all of them needing treatment). Sometimes, although the doctor was called by one member of the family for another member who was said to be ill, it might turn out that the caller himself was the sick person, or even that a third person, not mentioned before, was the true patient in need of help. In the majority of cases there was a very complex involvement of all members of the family. The patient for whom the doctor was called might well be ill, but the anxieties aroused in the patient's family were commonly very much in excess of the patient's own anxieties and degree of illness.*

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl®-1.

(norethindrone 1mg. c mestranol 0.05mg.)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

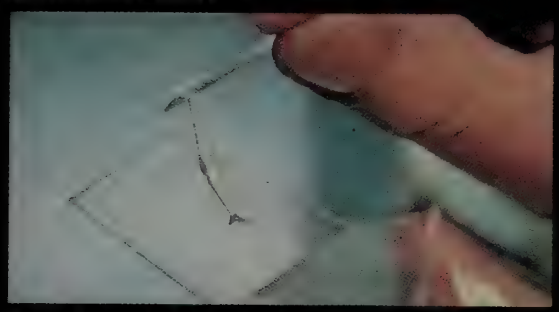
Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of NORINYL-1 (norethindrone 1 mg. with mestranol 0.05 mg.) in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with NORINYL-1. Therefore, if such tests are abnormal in a patient taking NORINYL-1 it is recommended that they be repeated after the drug has been withdrawn for two months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibromyomata may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. 5. NORINYL-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, and as in all cases of irregular bleeding *per vaginam*, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged NORINYL-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving NORINYL-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. 11. Because of the effects of estrogens on epiphyseal closure, NORINYL-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with NORINYL-1 may mask the onset of the climacteric. 13. The pathologist should be advised of NORINYL-1 therapy when relevant specimens are submitted.

Side effects observed in patients receiving oral contraceptives: The following adverse reactions have been observed in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression.

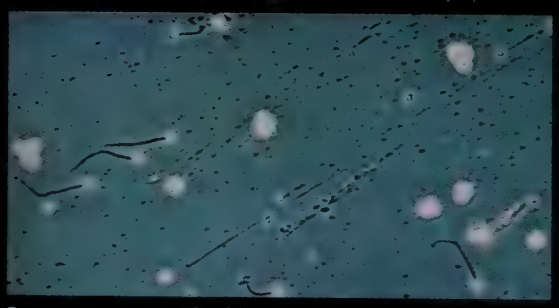
Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation post-treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption, itching.

The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has been neither established nor disproved): thrombophlebitis, pulmonary embolism, neuro-ocular lesions.



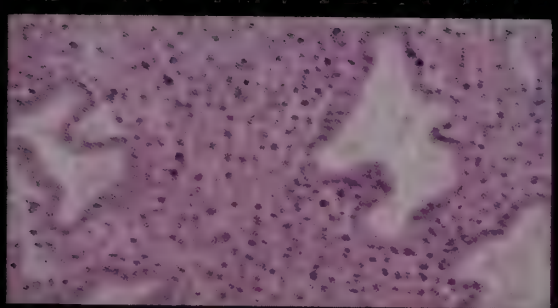
The following laboratory results may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, Factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from
SYNTEX
LABORATORIES INC., PALO ALTO, CALIF.



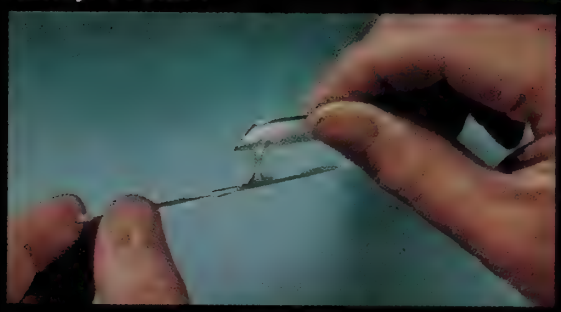
Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms.... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation. These effects are illustrated below.

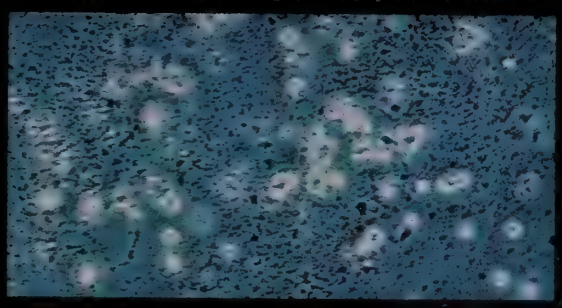


Untreated Patient

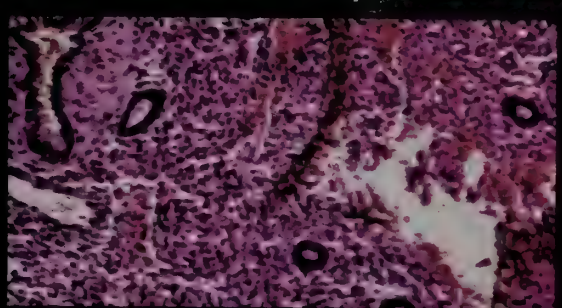
Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.



Spermatozoa appear healthy, active, freemoving.



Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.



Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.

Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl®-1
(norethindrone 1mg. & mestranol 0.05mg.) tablets

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

An uncommon steroid for common inflammatory dermatoses

In everyday topical steroid therapy, Synalar produces rapid resolution of inflammation and itching in steroid-responsive dermatoses—and at relatively low cost to the patient.

Advanced molecular design enhances potency

Synalar combines the advantage of earlier corticosteroid compounds with unique structural innovations. As a result, preparations of Synalar 0.01% and Synalar 0.025% have been reported to be more potent topically and significantly more effective than hydrocortisone 1.0%. The unique fluocinolone acetonide molecule provides one of the most useful topical corticosteroids for everyday practice.

Impressive clinical results in a wide range of dermatologic problems

The clinical efficacy of Synalar has been extensively documented in the world literature. Commonly encountered diseases such as allergic and contact dermatitis, eczematous and seborrheic dermatitis, and neurodermatitis respond rapidly to Synalar, often where previous therapy with other topical corticosteroids has failed.

Low patient cost for wider usefulness

With Synalar, a high degree of efficacy does not mean high price. And—a small quantity goes a long way. Thus, your patients can often obtain the "economy" of a hydrocortisone preparation with the proved efficacy of a potent, truly advanced steroid.

Synalar®
fluocinolone acetonide

Turn page for contraindications, precautions and side effects

For everyday topical steroid therapy

Synalar® 0.01%

fluocinolone acetonide provides economy in two practical dosage forms

For general use, the most economical and widely applicable concentration of Synalar is 0.01% Cream in a water-washable, vanishing cream base. Synalar Solution 0.01% is especially valuable in dermatoses involving moist, intertriginous areas or hairy sites where creams and ointments do not spread or penetrate readily. Synalar Solution is a unique dosage form—clear, nongreasy, cosmetically elegant.

Product Information

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. *Precautions:* Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. *Side Effects:* Side effects are uncommon with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. In such cases the agent should be discontinued and appropriate measures taken. *Availability:* Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Solution 0.01%—20 and 60 cc. plastic squeeze bottles. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

Clinical Path Conference

Abdominal Mass and Acute Leukemia

Dr. Robert L. Strom:*

A 56-YEAR-OLD WHITE female was admitted to Hennepin County General Hospital in early March 1965 complaining of weakness and abdominal pain. There was a history of subtotal hysterectomy for carcinoma of the uterus twelve years previously. A diagnosis of carcinoma of the cervix had been made two years prior to admission, and the patient was hospitalized and treated with external radiation and radium implants.

Two months after completion of her therapy she was hospitalized because of cough, fever, and diarrhea. A chest x-ray revealed bilateral pulmonary infiltrations, suggestive of pneumonia. At this time abnormal hematologic findings were first noted. The patient's hemoglobin was 10 grams %, her white blood cell count 1100 per cu. mm. and her platelet count 101,000 per cu. mm. She was treated with 6-Mercaptopurine, Prednisone, and Erythromycin and made an uneventful recovery.

After an interval of six months the patient was again admitted because of recurrent leukopenia and anemia. Her hemogram included a hemoglobin of 7.5 grams %, a white blood cell count of 1200 per cu. mm. with a differential count showing 81% paramyeloblasts. A platelet count was 52,000 per cu. mm. and a reticulocyte count was 3.6%. Her therapy consisted of a transfusion of whole blood, Methotrexate 5 mg. every other day and Prednisone 10 mg. daily.

The patient was again hospitalized three weeks later because of recurrence of anemia. Acute perineal ulceration had developed. Over a 30-day period a number of drugs were administered, including Vincristine, 6-Mercaptopurine, Prednisone, and Methotrexate. Her hemogram remained essentially unchanged except for a fall in the platelet count to 13,000 per cu. mm. She was discharged on Prednisone 40 mg. daily with oral penicillin.

A little later she was readmitted to Hennepin County General Hospital in a moribund state. On examination her blood pressure was 50/0, temperature 102.4°F., pulse 140 per minute, respiratory rate 40 per minute. She appeared acutely ill and was slightly jaundiced. The heart and lungs were normal to examination. The abdomen was acutely tender, especially to the right of the midline. A large mass was felt extending to the pelvis in the right hemiabdomen. Bowel sounds were absent. The perineal ulcerations were again present.

Laboratory Studies

Laboratory studies included a hemoglobin of 8.9 grams %, a white blood cell count of 650 per cu. mm. with neutrophils 26%, lymphocytes 54%, and paramyeloblasts 18%. A platelet count was less than 10,000 per cu. mm. The prothrombin time was 21.7 seconds with a control of 12.6 seconds.

The following blood chemistries were obtained. Blood glucose 186 mg.%, BUN 87 mg.%, serum sodium 125 mEq/L, potassium 3.9 mEq/L, CO_2 combining power 11 mEq/L and

*Associate Pathologist, Hennepin County General Hospital.

chloride 87 mEq/L. A total serum bilirubin was 4.8 mg.% with a 3 mg.% direct reacting fraction. The thymol turbidity was less than 1 unit and a cephalin flocculation was 4+ in 48 hours. The alkaline phosphatase was 11 KA units, a serum creatinine 5.6 mg.%, and a serum uric acid was 11.9 mg.%.

A chest roentogenogram was normal. An upright film of the abdomen revealed a "moderate amount of gas in the stomach."

The patient's treatment included intravenous hydrocortisone, digitalis, Kanamycin, vasopressor, and packed red blood cells. She expired acutely four hours after admission.

Clinical Discussion

Dr. Robert Green:*

In reviewing this protocol it appears to be easily divided into two parts. Initially, I would like to discuss her course, diagnosis, and management before she came to Hennepin County General Hospital, and secondly, her brief, acute terminal course.

In reviewing her past history, she appears to have had two malignancies, the first dating back 12 years, when she had carcinoma of the endometrium, followed by a two-year history of carcinoma of the cervix. Then she was hospitalized at another institution for what appeared to be an acute pneumonia which responded to therapy. At that time she was first diagnosed as having a leukemia manifested by leukopenia, mild thrombocytopenia, and abnormal cell morphology. It does not actually say in the protocol that a diagnosis of leukemia was made; however, she was treated with Prednisone and 6-Mercaptopurine, which are appropriate therapy for leukemia. She apparently made a satisfactory response to this therapy since there was a six-month interval before her next hospitalization. A blood smear on that next admission showed 81% paramyeloblasts, which confirms our suspicion that she did indeed have acute leukemia. Following several transfusions a course of Methotrexate was initiated and after a three-week interval she was started on a combination of antimetabolites, including Vincristine 6-Mercaptopurine and steroids. She was then discharged on a small dose of Prednisone and penicillin.

Shortly thereafter, she returned to this hospital for a brief terminal course, complaining of abdominal pain. At this time she was in shock and febrile. An abdominal mass was found and perineal ulceration was described. There were various abnormalities in her blood chemistries, all of which suggested a preterminal state. Then, despite intensive treatment, she expired.

Uterine Cancer and Leukemia

The only comment I have about her initial course is that the advent of her cervical carcinoma is certainly testimony against the performance of subtotal hysterectomy. One must not overlook the possibility of the presence of a residual cervical stump even in those individuals who state that they have had a total hysterectomy. We do not have the details of her irradiation; however, I assume she had the conventional therapy for cancer of the cervix with multiple portals delivering 3000 to 3500 roentgens to the cervix plus radium implants. I think it is safe to say that her cervical cancer irradiation sufficiently preceded the development of her leukemia to have very little, if anything, to do with it.

*Attending physician Hennepin County General Hospital.

Induction Therapy in Acute Leukemia

At this point I would like to comment on the type of leukemia and the mode of therapy. I reviewed the initial bone marrow sections and smears from 1965. As the marrow smears show a high percentage of blasts, I think one can readily make the diagnosis of acute leukemia. In studying the marrow, it appears to me that this was probably an acute myelogenous leukemia The acute leukemias are sometimes very difficult to classify on the study of the peripheral blood or bone marrow. In this one I tried to convince myself that I could see Auer rods. The implications of a diagnosis of myelogenous or lymphatic leukemia are a little different, even in adults. At that time, she was treated with 6-Mercaptopurine and Prednisone.

In reading the literature you may be somewhat confused by the various percentages of remissions induced in leukemia. Most of the good remissions reported refer entirely to acute lymphatic leukemia in children. This is an entirely different situation from acute myelogenous leukemia in either children or adults. In acute lymphocytic leukemia in children with appropriate induction therapy, we can expect an 80 to 90% remission rate. In adults with acute leukemia and particularly acute myelogenous leukemia, we are doing well if we can achieve a 10% remission rate. Most of the literature now indicates that induction therapy in acute myelocytic leukemia in adults still gives only about a 10% remission rate. This lady must have fallen into the 10%, because she had a very satisfactory remission induced by this combination of drugs. At least we don't hear anything more of her for another six months, and if she survived six months after initiation of treatment, I think one would have to consider this a good result. Most hematologists have seen patients who have responded to 6-Mercaptopurine and Prednisone, but the number of these patients is disappointingly few.

The next admission is occasioned by anemia and leukopenia. To comment on leukopenia and acute leukemia, in general: the prognosis is better if the leukocyte count is low. Patients with acute leukemia and high leukocyte counts have a generally poorer prognosis.

A study of the peripheral blood in this patient showed 81% paramyeloblasts. Often the clinical course in acute leukemia does not parallel the blast percentage in the peripheral blood and bone marrow. We see some patients with 25% blasts in the marrow running a very malignant course. On the other hand, we see patients with 90% blast forms who do not run such a malignant course.

On her second admission the patient was transfused and given Methotrexate. Now Methotrexate induction in acute myelocytic or lymphocytic leukemia in adults is, generally speaking, not very effective. Our current thinking is that Methotrexate and 6-Mercaptopurine are poor inducers but good drugs for sustaining remission. Here Methotrexate was given in rather unusual dosages, 5 mg. every other day, and we do not know for how long. There is now a regimen described by Huguley using Methotrexate for induction.[1] In this regimen a large dosage of Methotrexate is given orally: 2½ mg. every six hours for 20 doses. This is a very large dose, from which one can anticipate severe toxicity, but Huguley has succeeded in inducing some remissions in this way. I might just state that if the patient had had 5 mg. of Methotrexate intravenously or intramuscularly every other day rather than orally, we might have had a better prospect for remission. There are some reports that

Methotrexate intravenously rather than orally is more effective in inducing a remission.

VAMP Program

Then some three weeks later the patient returned; apparently this larger dose of Methotrexate was unsuccessful. At this point she was put on the Vincristine, 6-Mercaptopurine, Prednisone and Methotrexate program which most of you know is commonly called the VAMP Program, consisting of four drugs. The "V" stands for Vincristine, usually given in a dose of 25 micrograms per kilogram, generally resulting in a weekly dosage of 2 mg. intravenously. The "A" stands for Amethopterin or Methotrexate, given in a dosage of 2.5 mg. per day by mouth. The "M" stands for 6-Mercaptopurine, given in a dosage of 100 mg. per day by mouth. The "P" represents Prednisone, given in a dosage of 60 to 80 mg. per day. There are some variations of this program, such as one called "Vampette" which includes smaller doses; and there are other variations from the standard VAMP schedule. We have used VAMP here at Hennepin County General Hospital in a number of cases of acute leukemia with uniformly poor results; I myself have induced a remission in only one patient with acute myelogenous leukemia with this VAMP schedule. Many people are giving up this program for induction in acute leukemia in adults. However, there is apparently no better program than VAMP for inducing remission. Dameshek[2] has published a series in which he claims equal clinical results with 6-Mercaptopurine and Prednisone; but no one else can duplicate his results. The induction rate with VAMP, published from miscellaneous sources, is 40% remissions of varying duration in adults with acute myelocytic leukemia. I am sure this is optimistic.

I am making the point of differentiating induction from treatment or maintenance: a drug used for induction is not used for maintenance, and conversely. There are two new drugs not as yet available which may improve induction treatment. The first is Cytosine arabinoside, reported to induce remission in approximately 25% of adults with acute myelogenous leukemia. The other drug is Daunomycin or l-Asparaginase, an extremely toxic drug; but there has been some success in induction of remission in acute leukemia with this agent. In general, the second and third attempts at remission in acute leukemia are unsuccessful. We have our best chance of inducing a remission on the initial attempt.

The dosage of 5 mg. of Prednisone a day on which the patient was discharged is a drop in the bucket. If one is going to use Prednisone to induce a remission in adults with acute leukemia, one must use a large dosage, such as, a minimum of 60 mg. of Prednisone a day. There was a big scare about the usage of Prednisone by Wintrobe a few years ago, but I think most hematologists feel that high-dose Prednisone is the cornerstone of any treatment of acute leukemia in adults.

On her final admission, the patient came in with what I assumed to be septicemic shock. She had an abdominal mass with no bowel sounds and the perineal ulceration previously described. She was markedly leukopenic at this time, and it is not clear whether the VAMP therapy had reduced the blast count significantly. There was once again a thrombocytopenia, and the prothrombin time was elevated.

Steroid-Induced Diabetes

I would like to comment briefly on the presence of hyperglycemia. On none

of the previous admissions was hyperglycemia mentioned, and it is quite possible that this lady had steroid-induced diabetes. Prednisone therapy over a long period of time may have been at least partially responsible for this elevated blood sugar. She had a BUN of 87 mg% and markedly elevated creatinine suggesting that there was something adverse going on with the kidneys, tending to elevate the blood sugar.

Addisonian Crisis

She was hyponatremic and hypokalemic, and I wondered if she might have Addison's disease induced by exogenous steroid therapy. She had been discharged on 40 mg. of Prednisone a day; but we do not know whether she took it or not. It is possible that she may have had acute adrenal insufficiency, but I should think that her potassium would be somewhat higher, particularly in view of the renal insufficiency.

We find also that she was acidotic and moderately jaundiced. Most of the bilirubin elevation is direct-reacting or conjugated bilirubin, which suggests that this was obstructive jaundice rather than a hemolytic anemia related to her leukemia. Her alkaline phosphatase was not markedly elevated, and this would suggest that she did not have much of an obstructive component to her jaundice. The elevated uric acid might also be mentioned here. In acute leukemias of almost any form, the uric acid may be markedly elevated. Her basic disease plus her renal insufficiency adequately accounts for the elevated uric acid.

On her final admission, she had nothing in her lung fields to account for her fever. She had an abdominal mass, however, and I wonder if we could now review the x-rays to see if we can account for this intra-abdominal process?

Radiological Findings

Dr. S. H. Tsai:*

The chest x-ray is normal. An upright study of the abdomen is available, and we can see the upper margin of the abdominal mass adjacent to the inferior surface of the liver (Figure 1). But I cannot see the inferior or medial aspect of the mass. There is a dilated loop of small bowel in the mid-abdomen. The spleen is not particularly enlarged, and no free air is noted under the diaphragm. One has the general impression of a kidney outline on the right; however, this is quite indistinct. The exact relationship between the mass and the right kidney cannot be ascertained with certainty.

Discussion

Dr. Green:

Perineal ulceration appears on two occasions in the protocol, and I am not sure why. These ulcers in the perineum are probably the same sort of ulceration that occurs in the mouths of patients with leukemia and agranulocytosis which this lady manifested in the latter part of her course after her drug therapy.

Differential Diagnosis of Abdominal Mass in the Right Upper Quadrant

This reduces us to the differential diagnosis of her abdominal mass. What did this mass in the right side of the abdomen actually represent? And

*Chief of Radiology, Hennepin County General Hospital.

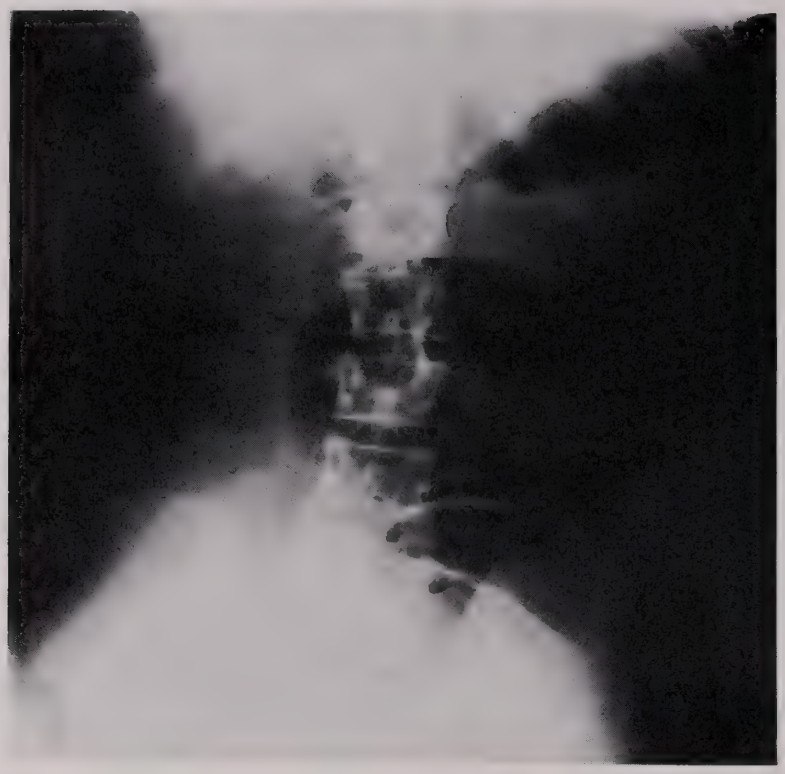

Fig. 1—Flat Plate of the Abdomen: An increased density is noted in the region of the right colon with an absence of bowel gas in the right hemi-abdomen.

how did it relate to her fever, shock and terminal course? There is nothing in the earlier portions of the protocol to indicate what this mass might be. We know that she was in grave condition because of her leukemia and the results of her treatment. Her tissue leukocyte count was decreased and she was on steroids which probably inhibited her response to infection.

Hepatic Enlargement

We could continue through a differential diagnosis of the right upper quadrant mass, and our initial thoughts might center about the liver since there was jaundice and an elevated prothrombin time. Leukemic involvement of the liver seldom produces this much hepatic enlargement. There must have been something complicating it, like congestive heart failure. She may have had serum-induced hepatitis from her previous admissions, but the evidence is insufficient. It is possible that with her leukemia and steroid therapy she had some sort of infra-hepatic or subhepatic abscess but we have no findings suggestive of this diagnosis on the chest x-rays. It is conceivable that she could have had metastatic cancer to the liver from one of her primary malignancies in the uterus, but there is little to suggest this, and her alkaline phosphatase was not markedly elevated.

Empyema of the Gallbladder

The gallbladder is in the right upper quadrant of the abdomen, and as she had abdominal pain and a tender mass, I assume that this could have been an

acute cholecystitis with empyema. However, in reviewing the films, she certainly had a large mass, the exact origin of which is not easy to ascertain.

Pancreatitis with Pseudocyst

I wonder if a serum amylase was done on this admission? That is the only other piece of laboratory information I would like to have. One would wonder if the abdominal mass could have represented a pancreatic pseudocyst or an ischemic portion of bowel.

The pancreas could be the source of the mass, since pancreatic pseudocysts develop after episodes of acute pancreatitis. An acute pancreatic cyst with hemorrhage into it can present as a right abdominal mass; however, it is more common to have the cystic masses present in the body or tail of the pancreas on the left. Such a cyst could cause an increase in bile duct pressure which would elevate the bilirubin. There is nothing much to suggest that the mass is coming out of the right kidney or from the retroperitoneal space.

Volvulus of the Right Colon

Another thing which might partially explain these findings would be some sort of catastrophe involving the right colon. This patient was undoubtedly emaciated and probably had a colon on a long mesentery which could have undergone a sudden volvulus with the development of an ischemic bowel and peritonitis. If she had a volvulus of her right colon, that could account for her pain, the electrolyte abnormalities, and her septic course with shock. To explain her terminal course, I would have to guess between some infectious process involving the gallbladder, a hemorrhagic pancreatitis, or some process such as a volvulus involving the right colon.

The management of her leukemia was apparently successful and a short remission was induced; but as so often happens, patients with leukemia die of infections. Since she had a prothrombin deficiency and a marked thrombocytopenia, an intra-abdominal hemorrhage or retroperitoneal hematoma would have to be considered. However, there was no mention of systemic purpura or hemorrhagic manifestations in the skin. Most patients with leukemia who die of hemorrhagic manifestations are bleeding everywhere, including their skin, nose and mucous membranes; but we have no evidence of that here. I would have to assume she died of a complication of her leukemia with infection and some process in one of the three organs giving rise to the intra-abdominal mass.

Clinical Diagnoses:

1. Acute myelogenous leukemia
2. Intra-abdominal abscess involving the gallbladder, pancreas or right colon
3. Septicemic shock

Pathology

Dr. Strom:

We were fortunate enough to be able to study the bone marrow slides from an outside institution taken on this patient in 1965 and early 1966. The section material from the bone marrow done early in 1965 appeared normocellu-

lar; however, the smears taken from this marrow showed increased numbers of primitive cells. In addition to the primitive blast cells, which numbered up to 5%, one noted a prominent left shift in the neutrophil series. The pathologist studying the material was probably faced with a familiar quandary; since there was no overgrowth of the hematopoietic elements in the bone marrow sections, but he was required to explain the ominous left shift in the neutrophil series. This initial marrow was interpreted as showing a striking left shift and neutrophilia.

The marrow study done in late 1965 shows a definite leukemia. The marrow sections are by this time totally overrun with myeloid elements, and I assume a definitive diagnosis of leukemia was made at that time. A smear from this study shows that nearly all the cells seen are blast cells and may be interpreted as paramyeloblasts. The cell nuclei are enlarged, rounded, and sometimes slightly indented, and they have a delicate chromatin network. Multiple nucleoli are frequently present in the nuclei. The cytoplasm of many of these blast cells is dark bluish grey, and some azure granules are noted. A few of these azure granules tend to line up, and one can convince oneself that Auer rods are seen in blast cells in rare instances. In addition, one sees vacuoles in the cytoplasm and sometimes overlying the nucleus, which are clear and sometimes slightly pink in color. I can understand why the hematologist called these cells paramyeloblasts, because in many ways they are not typical myeloblasts. One would have to think of some differentiation towards monocytes as well as granulocytes. I would like to classify this leukemia as being in the myelomonocytic group. One hematologist might prefer to call this the Naegeli type of monocytic leukemia, whereas another might consider it a variant of acute myelogenous leukemia with a terminal release of primitive reticulum cells. Not infrequently in the latter stages of chronic myelogenous leukemia in relapse one sees elevated leukocyte counts with increased numbers of primitive reticulum cells and young myeloid elements. Typical cellular elements from the peripheral blood as seen in late 1965 are shown in Figure 2. I was intrigued by the vacuolation in the blast forms, and I feel that if we had had some unstained material, a Sudan Black B stain of the blast forms might have been helpful in giving some insight into the direction in which the cell forms were differentiating. On the marrow smear taken in early 1966, 90 to 95% of the cells in the marrow were blast cells, thus confirming the diagnosis of acute leukemia (Figure 3). The number of developing red cells in the marrow was strikingly reduced. A paucity of mature cells in the neutrophil series was obvious.

Post-Mortem Examination

The pathologist naturally likes to be able to verify the diagnosis of acute leukemia at autopsy; but sometimes we have difficulty doing this. The hematopoietic organs held our initial interest during the post-mortem examination. The liver weighed only 1100 grams and was not particularly enlarged. The Kupfer cells in the hepatic sinusoids were seen to have ingested hemosiderin and foreign material, but these did not appear to be part of a leukemic process. The reason for the jaundice was relatively obscure since there was no evidence of common-duct obstruction. The lymph nodes were not enlarged either in the abdomen or in other areas of the body. The spleen was very small, weighing only 210 grams. We do not expect the spleen to be particularly

enlarged in cases of acute leukemia, so we must go to our section material to try to confirm the presence or absence of leukemic involvement of the spleen. There was some loss of definition between the malpighian corpuscles and red pulp; however, the lymphoid cells tended to aggregate around the cen-

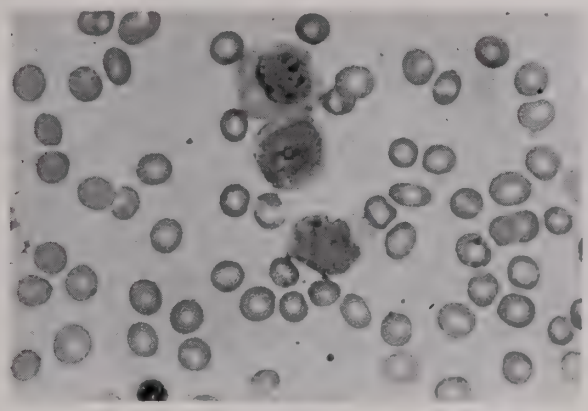

Fig. 2—Peripheral Blood. 100X: Two paramyeloblasts with clear and pink vacuoles are seen in the central portion of the field; a neutrophil myelocyte is seen at the top of the field.

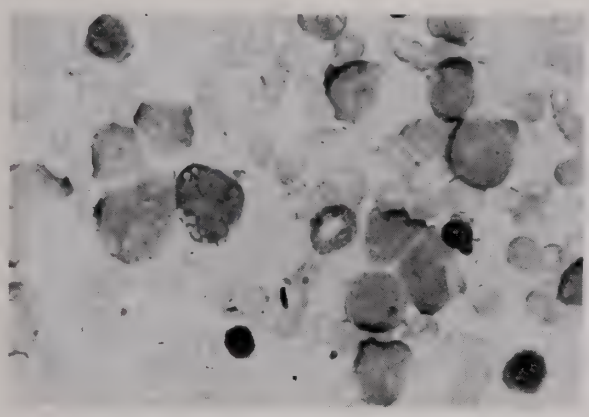

Fig. 3—Bone Marrow Smear. 100X: A preponderance of paramyeloblasts is seen in this view of the marrow, with only occasional normoblasts.

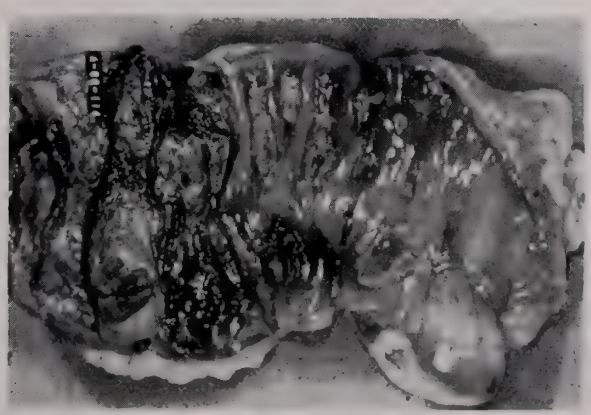

Fig. 4—Right Colon Mass when opened, showing ulceration, edema, and necrosis.

tral artery of the malpighian corpuscles, and the background reticulum was limited to the red pulp. An increased deposition of hemosiderin was seen in the red pulp; also some primitive reticulum and myeloid elements were present. Occasional megakaryocytes were observed, suggesting some myeloid metaplasia of the spleen.

Acute Colitis and Peritonitis

The gallbladder and pancreas were normal. We then focused our attention on the abdominal mass involving the right colon. As pictured in Figure 4, one can see that it was involved in a bizarre process characterized by thickening, edema, hemorrhage, and necrosis. When opened, the mucosa of the ascending colon and cecum showed extensive areas of ulceration with greenish discoloration suggestive of acute staphylococcal enterocolitis. Irregular mucosal projections extended into the lumen of the bowel, and I wondered on initial examination if this represented tumor or leukemic infiltration. A frozen section taken from one of the projections suggested only edema and necrosis without primary malignant infiltration (Figure 5). I imagine that Dr. Tsai is somewhat relieved that he did not have to evaluate a barium enema on this patient. As there was no evidence of mechanical volvulus or twisting associated with this bowel lesion, I can only assume that this was secondary to agranulocytosis with

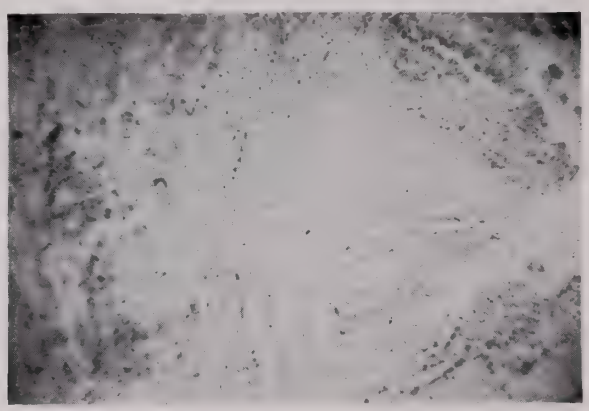

Fig. 5—Mucosa of Right Colon 40X showing necrosis, edema, and lack of tissue cellular response.

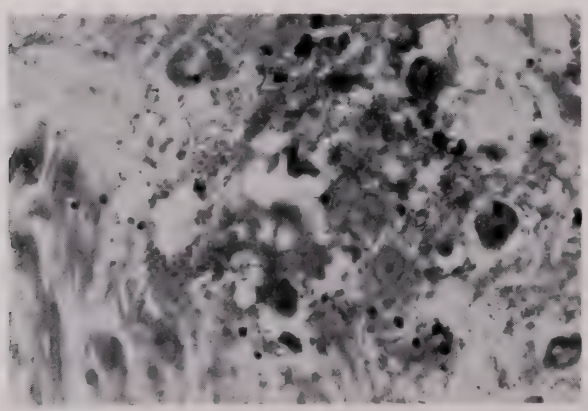

Fig. 6—Tissue Gram Stain 100X: Proliferating gram-negative rods are seen in the bowel muscularis not eliciting a cellular response.

suppression of the leukocytes in the tissue compartment. Much of the bowel wall was non-viable and there was evidence of an early peritonitis in the serosa. Colonies of proliferating gram-negative bacteria were seen in the external layers of the muscularis of the bowel (Figure 6). I can only assume that the leukocytic response in the tissue compartment was so inadequate, due to the therapy, that this unfortunate lady's bowel flora multiplied and penetrated the bowel wall, resulting in a systemic septicemia. Post-mortem blood culture studies revealed Paracolobactrum and Escherichia coli species, commonly isolated as part of the normal bowel flora, which under these circumstances had become pathogenic. There was evidence of associated vasculitis and pylephlebitis of the mesentery; but neither hepatic nor subhepatic abscess had supervened.

On examination of the adrenal glands one could see atrophy induced by exogenous steroid dosage, but there was no evidence of adrenal hemorrhage or Waterhouse-Friderichsen syndrome. Adrenal hemorrhage commonly complicates a gram-negative septicemia. I would not be in a position to comment on whether clinical adrenal insufficiency was present terminally, but it does not appear to be likely.

Pathological diagnosis:

1. Acute myelomonocytic leukemia (Naegeli type)
2. Acute colitis of the right colon with peritonitis
3. Terminal gram-negative sepsis due to bowel flora

Closing Comments

Dr. Strom:

Dr. Green, would you comment on the indications for surgical exploration in patients with acute leukemia? Certainly, surgical exploration did not appear to be indicated in a woman in this state of extremis; however, are there any indications for surgical intervention in patients with acute leukemia?

Dr. Green:

Obviously each case has to be individualized and most adults with acute leukemia are very poor surgical risks. In a case such as this with bacteremic shock, the patient was obviously no surgical candidate.

I would just like to emphasize this problem of the association of steroids and infection. We can divide the granulocyte pool into the circulating granulocyte pool, the marrow granulocyte pool, and the tissue granulocyte pool. Cartwright[3,4] has pointed out that the neutrophils can exchange from the marrow pool to the circulating pool, and the marginal leukocytes are part of the circulating pool. There are many more leukocytes marginated than are circulating, but with steroid therapy the circulating granulocyte pool increases. The administration of steroids will elevate the leukocyte count, since increased numbers of granulocytes are circulating. With steroid therapy there is a block and the neutrophils are not released freely to the tissues from the circulating pool. The granulocytes simply do not get to the tissues where they are needed.

A Medical Student:

Do people with solid tumors have a higher incidence of developing blood dyscrasias?

Dr. Green:

No, I do not think so. There is a higher incidence of cancer in patients with

leukemia than in non-leukemic patients, but the reason for this is obscure.

Dr. Strom:

I think the timing of the onset of leukemia in this case is somewhat interesting, however, because we have seen cases of leukemia following radiation for cancer of other types. I can remember two cases of acute leukemia that developed within six months after irradiation following a mastectomy for carcinoma of the breast. One might speculate in this case whether the onset of leukemia could be related to the irradiation of the cervix. There was no evidence of residual cancer in the cervical stump.

Dr. Green:

The only problem about that is that in the Hiroshima-Nagasaki victims who received a lot more total body irradiation, the interval between exposure and onset of their acute leukemias peaked out at approximately 18 months following exposure. Cases of acute leukemia began developing by nine to 10 months, but the peak incidence came much later. The time interval here appears to have been just a few months after her cervical irradiation.

Dr. Tsari:

I think also that a two-month interval is too short to incriminate irradiation as the cause of the acute leukemia. We do not know the stimulus that triggers acute leukemia.

Hedblom's Syndrome

This syndrome consists of an acute primary myositis of one or both leaves of the diaphragm with inspiratory pain, lower chest immobility, and upper abdominal pains without other signs of abdominal pathology. Joannides in 1935 described the lesion and suggested the eponymic term in honor of the thoracic surgeon Carl A. Hedblom.

Clinically, the onset may be sudden with a chill. The ipsilateral lower costal pain is frequently referred to the shoulder area. Fluoroscopic observations or roentgenographic studies reveal a gradual diminution and almost complete flattening of the normal dome of the diaphragm. Pathologically, there is swelling of the muscle fibers with leukocytic infiltration into the tissues. The pathology may be limited to the muscle bundles or may extend to the serous surfaces, the pleura, and the peritoneum. No constant or specific causative organisms have been recognized. The high incidence of trichiniasis of the diaphragm is well recorded but has not been related etiologically to this syndrome.

Differential diagnosis should exclude eventration of the diaphragm, spontaneous pneumothorax, acute surgical conditions in the abdomen, and epidemic diaphragmatic pleurodynia. Consideration must also be given to spontaneous pneumoperitoneum, irritation of the phrenic nerve trunk associated with mediastinal pathology, and pulmonary atelectasis. The condition is self-limited but has a tendency to recur. Broad-spectrum antibiotic therapy may be useful.

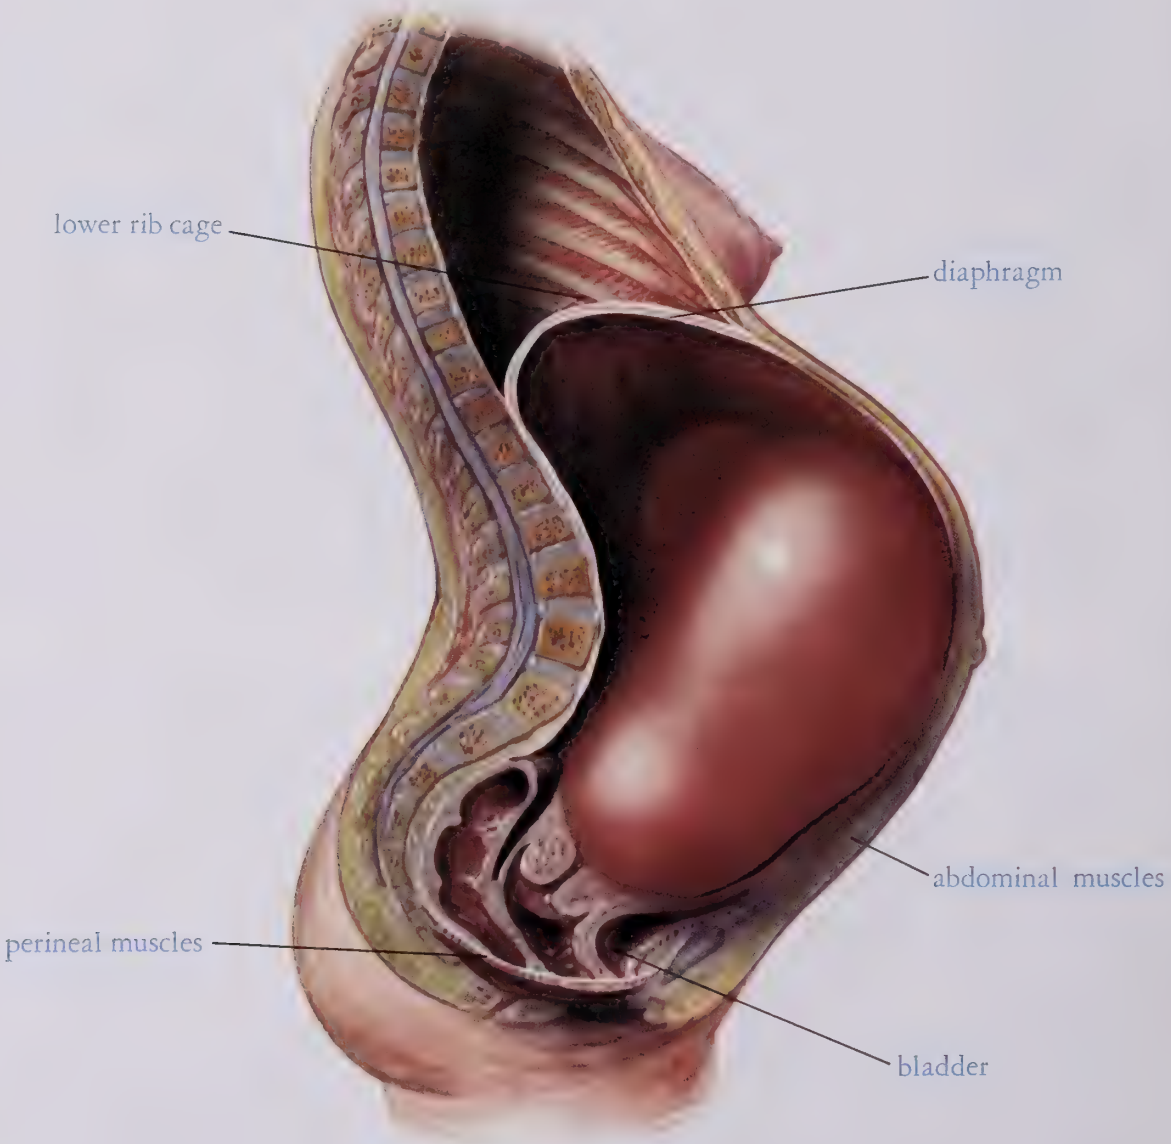
this issue: the cold in pregnancy...



the cold in pregnancy

Frederick W. Goodrich, Jr., M.D.
Senior Obstetrician and Gynecologist, Lawrence and Memorial Hospital, New London, Connecticut

Since pregnancy and the common cold are both ubiquitous, it is not surprising that they often occur at the same time in the same patient. Incidence figures are hard to come by, but the chances are very good that any given pregnant woman will have a cold at some time during the nine months of her gestation. When she does, she will tell you that it is the worst cold she ever had. It seems to last longer and the symptoms are more distressing than they are in the non-pregnant.

For purposes of this discussion, the common cold is considered to be the well-known symptom complex which includes sore throat, stuffy nose, and a cough. Febrile states or extension of the disease process into the lower respiratory tree are not part of the common cold and will not be included in this discussion.

The clinical picture of a cold in pregnancy can be confused by a long-known physiological phenome-

non. Kiesselbach's area in the nose (on the anterior part of the nasal septum above the intermaxillary bone) becomes engorged, apparently due to hyperemia induced by the increased estrogen level which accompanies pregnancy. The amount of congestion can vary in degree from woman to woman. Some have very little congestion, others will have occasional nosebleeds from this area, still others will have symptomatic congestion to the degree that they will complain of having a "chronic" or constant cold.

Less well recognized is the occurrence of this type of hyperemia in any part of the nasopharyngeal mucosa, again in varying degree. Such swelling often produces a postnasal drip which, the patient will state, is present only when she is pregnant. Patients who do not have symptomatic congestion ordinarily, will find that when they do get a cold, the symptoms last much longer than those of a cold usually do. Occasionally, this hyperemia is responsible for closure of the medial end of the Eustachian tube; such patients will complain of "plugging" of the ears. Inspection of the ear drum will show a depression which confirms the presence of Eustachian closure rather than wax in the canal which is the patient's diagnosis. Symptoms related to this physiological congestion are more apt to occur in heavier smokers or those who have a history of allergic rhinitis, just as are the symptoms of the common cold. And when the cold does occur in pregnancy, the symptoms are worse because of the underlying congestion.

The pregnant woman with a cold is miserable for other reasons, dependent somewhat on her parity and the length of her gestation. As parity increases, so also does the relaxation of the abdominal and perineal musculature. The uterus, lying against a slack abdominal wall, and bearing down on relaxed perineal muscles, acts like a piston when the patient coughs, sneezes, or even blows her nose, pushing down on the bladder. Stress incontinence during colds is almost the rule.

As the length of gestation increases, so does the size of the uterus. As it grows, it pushes the abdominal contents above it and elevates the diaphragm. This results eventually in a lateral displacement of the lower rib cage, often to a point at which the patient will complain of soreness in this area. If such a

From a continuing study on nasal congestion...

timed to work while your patient does

A study begun in 1966 by the Department of Otolaryngology, Greater Baltimore Medical Center, has accumulated evidence that documents the effectiveness of Triaminic's timed-release action in the treatment of nasal congestion.

With its balanced formulation of an oral nasal decongestant and two antihistamines, Triaminic effected partial or complete relief in more than 82% of the 85 subjects treated. Clearing nasal obstruction. Reducing turbinate swelling. Making breathing easier.

It's a comforting thing to know that Triaminic really works.

Triaminic® *timed-release tablets*

Each timed-release tablet contains:

Phenylpropanolamine hydrochloride	50mg.
Pyrilamine maleate	25mg.
Pheniramine maleate	25mg.

Side effects: Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. Precautions: The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

(Advertisement)

patient has a cold, the coughing and sneezing will exaggerate this soreness. The diaphragmatic restriction caused by the enlarging uterus also makes breathing more difficult, particularly when the patient lies down. A cold compounds this difficulty.

Treating a cold in pregnancy requires two additional considerations. The patient should be told that the symptoms may last longer lest she become discouraged, and she should be reassured that the treatment will not damage the fetus. Although there are still some women who seem blissfully ignorant regarding matters of health (and these need to be cautioned not to take medication recommended by friends), most of our maternity patients are aware of the thalidomide tragedy. These women need constant reassurance that the symptoms of a cold can be treated, and that the medication is safe. Fortunately, many of the drugs which are of benefit have been in use long enough and widely enough so that such a statement can be offered. Occasionally one encounters a patient who is so anxious to avoid medication that she is extremely reluctant to take anything at all. Since cold is self-limited, it seems reasonable enough to give such a patient the choice and not to force drugs on her if she is obviously afraid of taking them.

The most distressing symptom of the common cold is the nasal congestion. This can be mitigated by the use of a decongestant which will help reduce the postnasal drip and the coughing caused by it. The kind of a cough which is described as a "tickling" in the throat and which is apt to occur when the patient goes to bed is usually due to nasopharyngeal congestion rather than inflammation in the lower respiratory tract.

There are many cough mixtures available. Most contain an antihistamine, a decongestant, and a cough "suppressant." Should cough suppression be desirable, it is important to remember not to use both a decongestant tablet and such a cough mixture as the patient would be getting a double dose of the decongestant. With some patients, the placebo effect of a cough syrup may be important and a liquid preparation might be substituted for an oral tablet.

For a sore throat, candy drops or lozenges at frequent intervals are soothing. It is not only unnecessary but unwise to use antibiotic lozenges or drops. The use of antibiotics in an uncomplicated cold is contraindicated and should be scrupulously avoided.

In summary, a cold in pregnancy is more severe and longer lasting. The treatment of the symptoms with local and systemic decongestants will make the patient more comfortable.

Apparently the cold is so common in pregnancy that it has received very little attention in the literature. References are almost non-existent and the few which are available add little to the common knowledge, are out-dated, or are not helpful. Thus the usual bibliography is not appended.

Relieve his sniffles, her concern, and about half your phone calls. Tell her to get "The Orange Medicine"

Triaminic® syrup

Each teaspoonful (5 ml.) contains:

Phenylpropanolamine hydrochloride	12.5 mg.
Pheniramine maleate	6.25 mg.
Pyrilamine maleate	6.25 mg.

For nasal congestion you can bring quick, lasting comfort to your little patients with Triaminic Syrup. You may occasionally encounter these side effects: drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. Precautions: the possibility of drowsiness should be considered by patients engaged in mechanical operations requiring alertness. Use with caution in patients with hypertension, heart disease, diabetes, or thyrotoxicosis.

Grand Rounds

Stevens-Johnson Syndrome

M. THOMAS STILLMAN, M.D.
Medical Resident

STEVENS-JOHNSON syndrome has been considered an "acute inflammatory systemic disease producing a variety of clinical patterns."[1] Although the clinical manifestations are well recognized, the pathogenesis and presumed etiology remain as medical mysteries. The literature is filled with case reports of this syndrome whose causal role could well be challenged.

Classification

The classification of Stevens-Johnson syndrome has met with much uncertainty and confusion. Alexander and Cope[2] reviewed the historical development of this syndrome.

Skin Lesions

In 1860, Hebra reported on an acute illness characterized by the presence of a polymorphic skin eruption. He called this illness "erythema multiforme exudativum," and the skin lesions consisted of irregularly shaped areas of erythema, papules, vesicles, and bullae. In 1862, Bazin noted the presence of constitutional symptoms and oral lesions with this skin eruption.

Oral and Ophthalmic Skin Lesions

The oral lesions were better described in 1882 by Quinquaud. In 1896 von During described in detail the presence of conjunctivitis. The syndrome as we picture it today was described by Stevens and Johnson[3] in 1922 when they reported two cases of an eruptive fever associated with stomatitis and ocular complications. In 1951, Ashby and Lazar[4] suggested the term "erythema multiforme exudativum major" to distinguish the more severe variants

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, September 19, 1967.

from the "minor" or mild forms as originally described by Hebra. The nomenclature has been very confusing, and this is reflected by the number of synonyms used since Stevens and Johnson's description in 1922. Some of the synonyms include: erythema multiforme pluriorificiales, mucocutaneous fever, eruptive fever with stomatitis and ophthalmia, ectodermose erosive pluriorificelle, the triple complex, mucosal respiratory syndrome, dermatostomatitis, erythema bullosum malignans pulriorificial type, and erythema polyforme bulleux. One could say that we are probably dealing with degrees of intensity in a spectrum of clinical reactions that vary from mild to fatal manifestations.

Clinical Manifestations

The general clinical manifestations of this syndrome have been well described.[5-11] The prodromal period varies from one to fourteen days and is characterized by such general symptoms as fever, cough, malaise, coryza, sore throat, myalgia, chest pain, and arthralgia in varying combinations. This is followed by the skin and mucous membrane eruption together with various visceral involvements.

Skin

Initially, rapidly developing skin lesions may be the only manifestation. The rash is usually symmetrical and starts on the extensor surfaces of the hands, arms, and feet. The entire body may become involved, but the scalp is usually spared. The lesions start as erythematous areas that may become papular, vesicular or even bullous. Macules may show a fading center, or hemorrhage may occur into affected areas, thus giving rise to the so-called target, iris, or bull's-eye lesion. If the disease progresses, erosion, ulceration, and scaling may occur, leaving areas of the body stripped of epidermis.

Mucous Membrane

Characteristically the mucous membranes are equally involved with the skin. The most commonly involved areas are the nose, mouth, and eyes, but the genitalia and anus may also develop lesions. The buccal mucosa may become fiery red with scattered petechial hemorrhages. There may be marked swelling and intense pain within the mouth. Vesicles develop that soon rupture, leaving ulcers oozing with bloody serum. These ulcers then darken with clots or are covered with a typical gray-white pseudomembrane. The lips are often covered with a bloody crust, and eating and drinking becomes very difficult. The pharynx and esophagus may become involved and the patient often spits up blood-stained pus.

Ocular

The ocular manifestations of this syndrome are common but highly variable. Howard[9] reviewed the eye manifestations in detail. There is no pathognomonic eye lesion, and mild conjunctival injection may be the only finding. Conjunctivitis is common and the discharge is catarrhal, purulent, or pseudomembranous. The lids may become swollen and ulcerated, and iritis, iridocyclitis and panophthalmitis may develop. Corneal involvement with opacification or pannus formation leads to partial or total blindness in the involved eye. In chronic cases, photophobia, blepharospasm, persistent mucinous discharge, and immobilization of the globe are possible complications.

Since the advent of sulfonamides and antimicrobials, severe ocular damage is less frequent. In Howard's study of 61 patients, 10 developed severe ocular signs, two of whom were left with visual loss.

Sex and Age

The genitalia may be involved in either sex. In the male, penile and scrotal ulcerations occur and in the female vulvovaginitis. In both sexes, a urethritis occasionally occurs, associated with a thin, purulent discharge. The anal mucocutaneous junction becomes involved and results in denudement of the perianal skin. The sex ratio was 58% males to 42% females and the age range was two to 72 years. About 55% were below the age of 20 and 30% below the age of ten years.

Systemic Manifestations

The systemic symptoms are highly variable, depending upon the degree of involvement. Temperature ranges from 101° to 104° F. The attack may last from several days to six weeks, and recurrences or exacerbations have occurred year after year in as many as 25% of the cases.[1] In a review of 31 cases of Stevens-Johnson syndrome,[5] the various clinical manifestations were tabulated (Table 1).

TABLE 1

Clinical Feature	Number of Cases
Rash	30
Stomatitis	27
Conjunctivitis	26
Pharyngitis	18
Cutaneous bullae	17
Pneumonitis	12
Urethritis and/or balanitis and/or vaginitis	10
Anal involvement	3

*From Claxton, R. C.: Med J Aust 1:963, June, 1963.

Mortality

Mortality figures are difficult to obtain. In Claxton's series of 31 cases, there was one death. Earlier studies[4] report mortality figures as high as 10 or 12%. Single case reports in the literature include fatal cases.

Differential Diagnosis

The differential diagnosis may be confusing, especially in the younger patient. Some of the more common disorders to distinguish from Stevens-Johnson syndrome are summarized in Table 2. It should be noted that the laboratory is of no help in specifically diagnosing this syndrome.

Pulmonary

The literature reports involvement of other organ systems in Stevens-Johnson syndrome.[12-14] Of particular interest is the frequency of pulmonary manifestations. In Ashby's and Lazar's analysis of 81 cases, bronchitis or bronchopneumonia occurred in about 30%.[4] The pneumonia is indistinguishable clinically and radiologically from primary atypical pneumonia. A patchy

bronchopneumonia with densities extending out from prominent hilar shadows, often bilateral, is the usual radiographic picture. The term "mucosal respiratory syndrome" was popularized in the Canadian literature because of the frequency of pulmonary involvement. Pneumonia as a manifestation of this syndrome probably represents the greatest single threat to life.[17-18] At autopsy the lungs are heavy and meaty and are studded or completely consolidated with yellowish necrotic zones. There have also been fibrinous exudates covering the lungs. The bronchi described contain thick, creamy, mucoid material thought to be secondary to similar eruptions involving other mucous membranes.

Gastrointestinal

The gastrointestinal tract may be involved in this syndrome. Boe and others[16]

TABLE 2

Guidelines in Differential Diagnosis of Stevens-Johnson Syndrome

Disorder	Distinguishing Characteristics	Laboratory Test
Stevens-Johnson syndrome	Skin lesions are succulent, erythematous papules with "iris" or "bull's-eye" lesions in innermost areas; mucous membranes of the nose, mouth, ears, vagina, rectum, and scrotum may have bullae or vesicles; partial or complete loss of vision may result from ocular lesions.	None
Toxic epidermal necrolysis (Lyell's disease)	Large areas of skin become loose and peel, resembling effect of scalding.	Nikolsky's sign (superficial layer of skin can be rubbed off with light pressure)
Chickenpox	Skin lesions are pruritic and progress in an orderly fashion. Bullous lesions are rare on skin but common in mouth.	None
Vaccinia (following smallpox vaccination)	Lesions progress in stages similar to those of original vaccination; no bullous or polymorphous erythematous lesions appear.	Vaccination 10 to 14 days previously
Diphtheria	Grayish-white thick membrane in throat	Organism isolated
Pemphigus	Protracted course; less polymorphism and configuration	Skin biopsy shows presence of acantholysis
Pemphigoid and bullous dermatitis herpetiformis	More chronic; less mucous membrane and systemic involvement	Skin biopsy shows presence of acantholysis
Bullous contact dermatitis	Location and configuration of lesions suggest external factors; no mucous membrane or systemic symptoms appear; there is a history of allergy.	Patch testing for allergen
Lymphoma	Occasional polymorphous skin lesions appear but clinical picture is sufficient for differentiation.	Biopsy
Septicemia (with blebs)		Identification of infective material
Systemic lupus erythematosus (LE)	There may be typical "butterfly" skin lesion but no erosive vesicular mucous membrane lesions.	Skin punch biopsy; positive LE test; accelerated ESR
Herpetic stomatitis	There are acutely painful lesions on borders of lips and oral mucosa, along with mild constitutional symptoms; the lesions tend to roll with tissue.	Tissue-culture isolation of virus, complement-fixation test

[7]Coursin, D. B.: JAMA 198:134, October 10, 1966.

reported three deaths attributed to gastrointestinal lesions. In two cases the lesions were very much like ulcerative colitis. Other gastrointestinal involvement included necrotizing esophagitis, superficial ulcerations throughout, as well as generalized congested and edematous mucosa. Sigmoidoscopy does not separate the intestinal lesions from ulcerative colitis.

Cardiac

Schartum[13] reported two cases of Stevens-Johnson syndrome with cardiac involvement. One case was that of a 49-year-old man who developed atrial fibrillation and pericarditis with congestive heart failure. The patient recovered completely with the healing of the skin lesions. The other case was also that of transient atrial fibrillation. The author reported that an acute interstitial myocarditis has been noted at autopsy study in a fatal case of Stevens-Johnson syndrome.

Renal

Comaish and Kerr[14] concluded in five cases that an inflammatory renal lesion similar to acute glomerulonephritis is associated with erythema multiforme. This was manifested by albuminuria, microscopic hematuria, cylindruria, and uremia. Hypertension and oliguria were not part of the acute attack. Two of the patients had previous infection by Streptococcus, but not Type 12. The authors pointed out that fatal uremia may develop during the acute illness and recurrent episodes may produce chronic nephritis.

TABLE 3
Attributable Causes of Stevens-Johnson Syndrome

Drugs	Infections	Contactants
Amithizone	Viral	Poison Ivy
Antitoxins	Herpes simplex	
Antidiabetic agents	Coxsackie	
Arsenic	Echo	Internal Malignancies
Barbiturates	Other	
Belladonna	Mycoplasmal	
Bromides	Atypical pneu.	X-ray
Carbamazepine	Bacterial	
Chloroquine	Diphtheria	
Codeine	Erysipeloid	Vaccines
Digitalis	Pneumonia	
Gold salts	Pharyngitis	BCG
Hydantoin	Psittacosis	Polio
Hydralazine	Tuberculosis	Smallpox
Iodides (cough meds)	Tularemia	
Meprobamate	Typhoid fever	
Mercurials	Mycotic	Hormonal
Penicillins	Coccidio	
Phenacetin	Histo	Menses
Phenicarbazide	Protozoan	Pregnancy
Phenolphthalein	Malaria	
Phenylbutazone	Trichomoniasis	
Pyrazolone	Vaginitis	Unknown
Pyrinium		
Quinine		
Salicylates		
Succinimide	Collagen Diseases	
Sulfonamides		
Tetracycline	Food	
Thiouricil	Margarine	
Trimethadione	Chocolate	

Finally, central nervous system involvement with meningoencephalitis has been reported in association with this syndrome.[19]

Histopathology

In erythema multiforme, there is increasing damage to vessels in the dermis. The macule (dilated vessels with subepidermal edema) may increase to papules that develop into "cleavage" vesicles, containing mainly mononuclear cells. Interpretation is that of atypical chronic inflammatory change. Some stress the point that lymphocytes show a tendency towards perivenous localization. Mucosal lesions are similar. Alexander and Cope[2] summarize the histologic abnormalities by (a) epithelial ulceration and (b) widespread necrosis of arterioles and venules with fibrinoid degeneration of associated collagen. They feel that these findings are those of a hypersensitivity reaction. Pearson[20] reported on the ultrastructural alterations at the dermo-epidermal junction in selected blistering diseases. He demonstrated with the electron microscope a striking necrosis of the cytoplasm within the basal cells.

Etiology

The etiology of Stevens-Johnson syndrome remains obscure. Erythema multiforme is a clinically distinct skin reaction of multiple etiologies and is thus considered a syndrome rather than a disease. Coursin[8] points out two main theories: (1) that this syndrome has a single etiology, probably an infectious agent, and (2) that this syndrome represents a symptom complex associated with a large number of conditions, including bacterial infections, viral infections, certain drugs, and a whole host of other miscellaneous conditions.

Bacterial

Many bacterial infections have been cited as attributable causes of this syndrome. These have included diphtheria, various bacterial pneumonias, psittacosis, tuberculosis, tularemia, and typhoid fever. Recurrent streptococcal pharyngitis and tonsillitis have been especially well documented.[14]

Viral

Viral infections are considered causative by many.[12-28] Schmidt[28] isolated herpes simplex virus from an aspirate of a vesicular lesion occurring in this syndrome. Antibodies demonstrated by the herpes virus complement fixation test showed an appropriate rise and fall. Shelley[27] reports a patient who had recurrent erythema multiforme over seven years, each attack being preceded by herpes simplex infection. Herpes simplex has been observed in more than 15% of patients with recurrent erythema multiforme. It was Shelley's feeling that these patients demonstrate a unique hypersensitivity reaction to the herpes simplex antigen. In his patient this was illustrated by repeatedly reproducing vesiculobullous lesions of erythema multiforme type by the intradermal injection of a herpes simplex antigen. The author also points out that herpes simplex may be present in reservoirs such as the vagina and vulvar area, oropharynx, conjunctiva, or penis, and may be activated by various diseases. Other associated viral diseases include measles, mumps, varicella, Coxsackie and Asian influenza.

Of recent interest has been the association of Stevens-Johnson syndrome

with primary atypical pneumonia caused by Mycoplasma pneumoniae.[21-23] Strom [23] reported 16 patients with elevated cold agglutinins and primary atypical pneumonia who developed this syndrome. Four of these patients received drugs prior to the onset of the Stevens-Johnson complex.

Drugs

A host of drugs have been implicated in the etiology.[29-36] Of special interest is the well recognized association with the sulfonamides. Carroll and others,[32] in an FDA survey collected on a worldwide basis, report 116 cases of Stevens-Johnson syndrome associated with long-acting sulfonamide therapy. These were collected over a period from 1957 to 1965. Eighty-one cases occurred in the United States, 27 in adults (33%). Of these 27 patients, five died. The median time of onset of the reaction was about the tenth day following beginning of drug therapy, with a range of two to 24 days. In Claxton's review[5] of 31 cases eight (25%) were attributable to sulphonamides, while in Ashby and Lazar's series of 81 cases, seven (9%) had received sulphonamides previously.[15] Drugs in general were implicated in 42% of Claxton's cases.

Other Factors

Other miscellaneous causes linked to this syndrome have been reported,[37-39] including vaccinations, malignancies, deep x-ray therapy, pregnancy, contactants such as poison ivy, collagen diseases, and foods.

The sudden and widespread mucocutaneous involvement in Stevens-Johnson syndrome caused by such varied factors strongly suggests an allergic or hypersensitivity syndrome. Mackie[40] suggests that initially antibodies are made by the usual immune mechanisms in response to an antigen. A "distorting factor," most likely a drug (quinoneimine breakdown product of sulfonamides), produces distorted antibodies that lose their selectivity for the primary antigen and exert a damaging effect on the normal body.

Treatment

Stevens-Johnson syndrome is considered a self-limiting disease and no specific therapy is available. The course of this syndrome appears to be independent of the type of therapy given. Since this is felt to be a hypersensitivity syndrome, steroids and antihistamines are recommended for the severe cases, but results reported are highly inconsistent. High doses given over a short period are thought to shorten the course of the syndrome. Topical and/or systemic antibiotics are recommended for secondary infection. Symptomatic care for mouth pain, using anesthetic mouth washes as well as proper local therapy for the skin and genitalia, is advised. Local treatment to the eyes becomes extremely important to avoid the serious ocular complications. This includes topical antibiotics and steroids along with warm, moist compresses to avoid the chance of scarring. No attempt should be made to remove any pseudomembranes from the eyes. If drugs are implicated, they should be discontinued.

Summary

Stevens-Johnson syndrome is best defined as an acute inflammatory systemic disease producing a spectrum of clinical patterns. Of primary impor-

tance is the mucocutaneous eruption involving the skin, eyes, nose, mouth, and genitalia. The systemic manifestations are variable, and involvement of the gastrointestinal, pulmonary, cardiac, renal, and central nervous system has been reported. This syndrome is more prevalent in persons under 20 years of age, is somewhat more common in males, and tends to recur in 25% of the cases. Mortality figures range from three to 12%. The etiology remains obscure, but various bacterial and viral infections, and drugs, especially sulfonamides, have been described as causative. The sudden and varied nature of Stevens-Johnson syndrome along with the histopathology strongly support the hypothesis that it is a manifestation of an allergic or hypersensitivity reaction. Although this syndrome is mainly self-limiting, steroids probably shorten its course and are recommended in severe cases.

Case Report

A 22-year-old white male was admitted to Hennepin County General Hospital because of a stomatitis. The patient had noted the onset of a purulent conjunctivitis four days prior to admission. Three days prior to admission a "cold sore" appeared on his lower lip that rapidly progressed to ulcerating lesions over the entire mucosal surface of the mouth. During this time he noted the appearance of erythematous skin lesions on his arm. Two days prior to admission, a clear discharge was seen from the penis. The patient took no drugs and his past medical history was unremarkable.

Physical examination revealed a normotensive young male, temperature 101°, who appeared quite toxic and in distress from pain in his mouth. The patient's conjunctiva were markedly injected bilaterally and there was a serious discharge from the eyes. The corneas were clear. The lips were dry and crusted along with ulcerative lesions. There were ulcerative lesions within the mouth, involving the buccal mucosa extending over the soft palate. Gray-white membranes covered many of these lesions. There were scattered discrete annular erythematous skin lesions over the extensor surfaces of both arms. Some lesions were vesicular with hemorrhagic centers giving the appearance of target lesions. The mucocutaneous junction of the anus was inflamed, and there was a meatal ulcer with clear drainage present on the penis. The rest of the examination was within normal limits.

Initial hemogram, chest film, electrocardiogram, urinalysis, and blood chemistries were normal. VDRL, heterophile, lupus erythematous prep, and cold agglutinin were negative. Throat cultures grew out alpha strep; conjunctival fluid cultures grew out staph; coagulase and urethral cultures were essentially negative. Acute and convalescent sera were negative for herpes simplex.

The patient was placed on parenteral fluids along with penicillin. His mouth pain was relieved with demerol and xylocaine mouth wash. He improved slowly with spontaneous resolution of all his lesions, and he was discharged on the tenth hospital day. There has been no apparent recurrence of signs or symptoms. His discharge diagnosis was uncomplicated Stevens-Johnson syndrome, etiology undetermined.

The dollar doesn't go far these days. Worse yet, it seldom finds its way back.—Changing Times

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

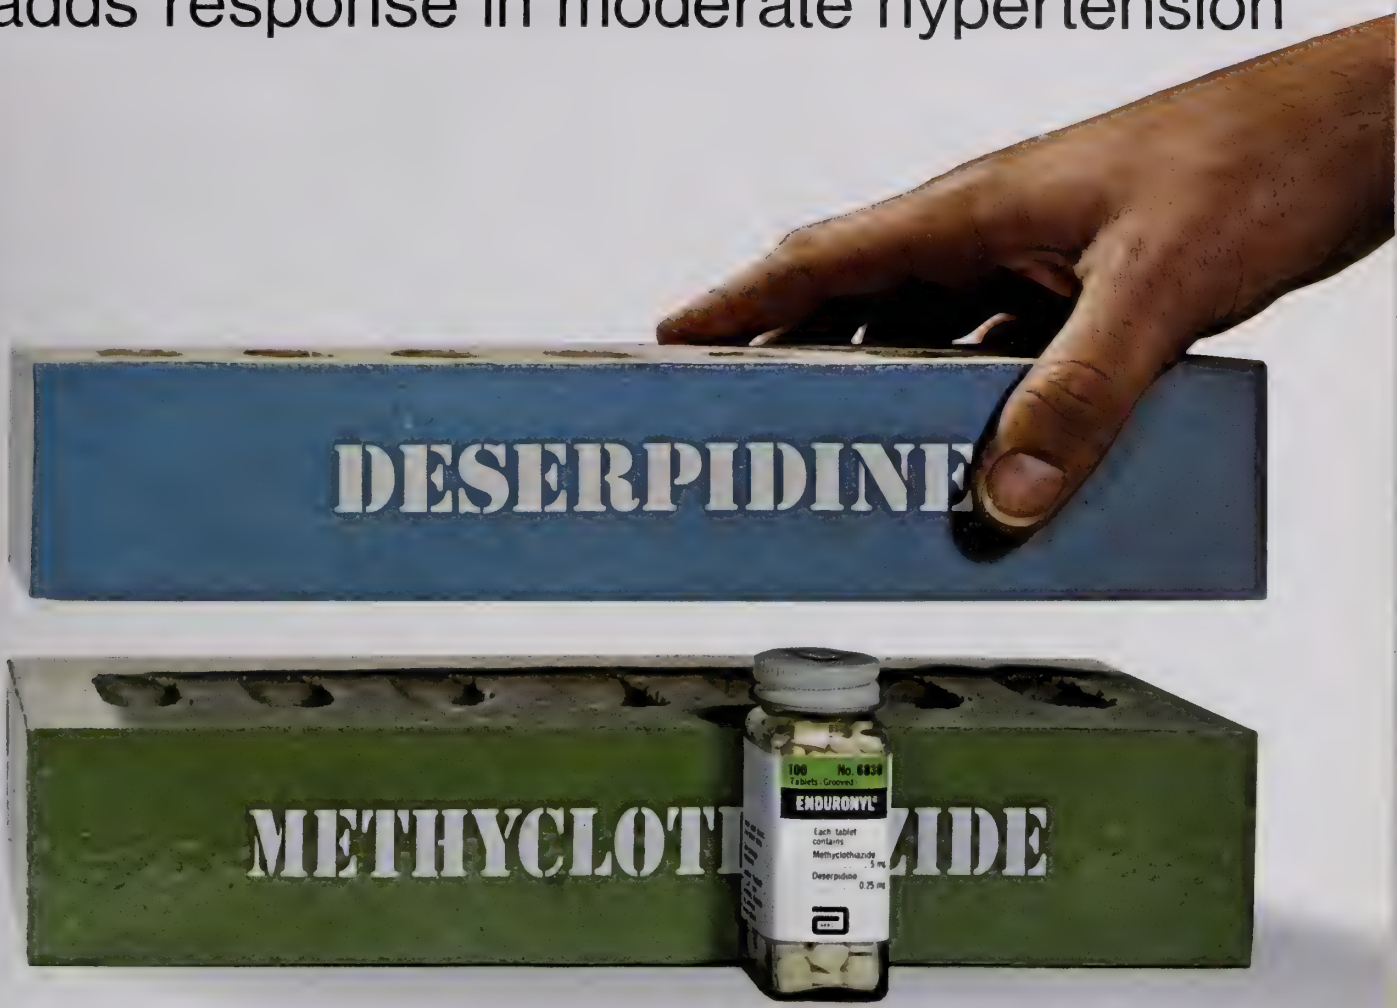
The therapeutic action is smooth, and persits for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

Of course, as with all thiazides, supplemental dietary potassium should also be considered.

Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

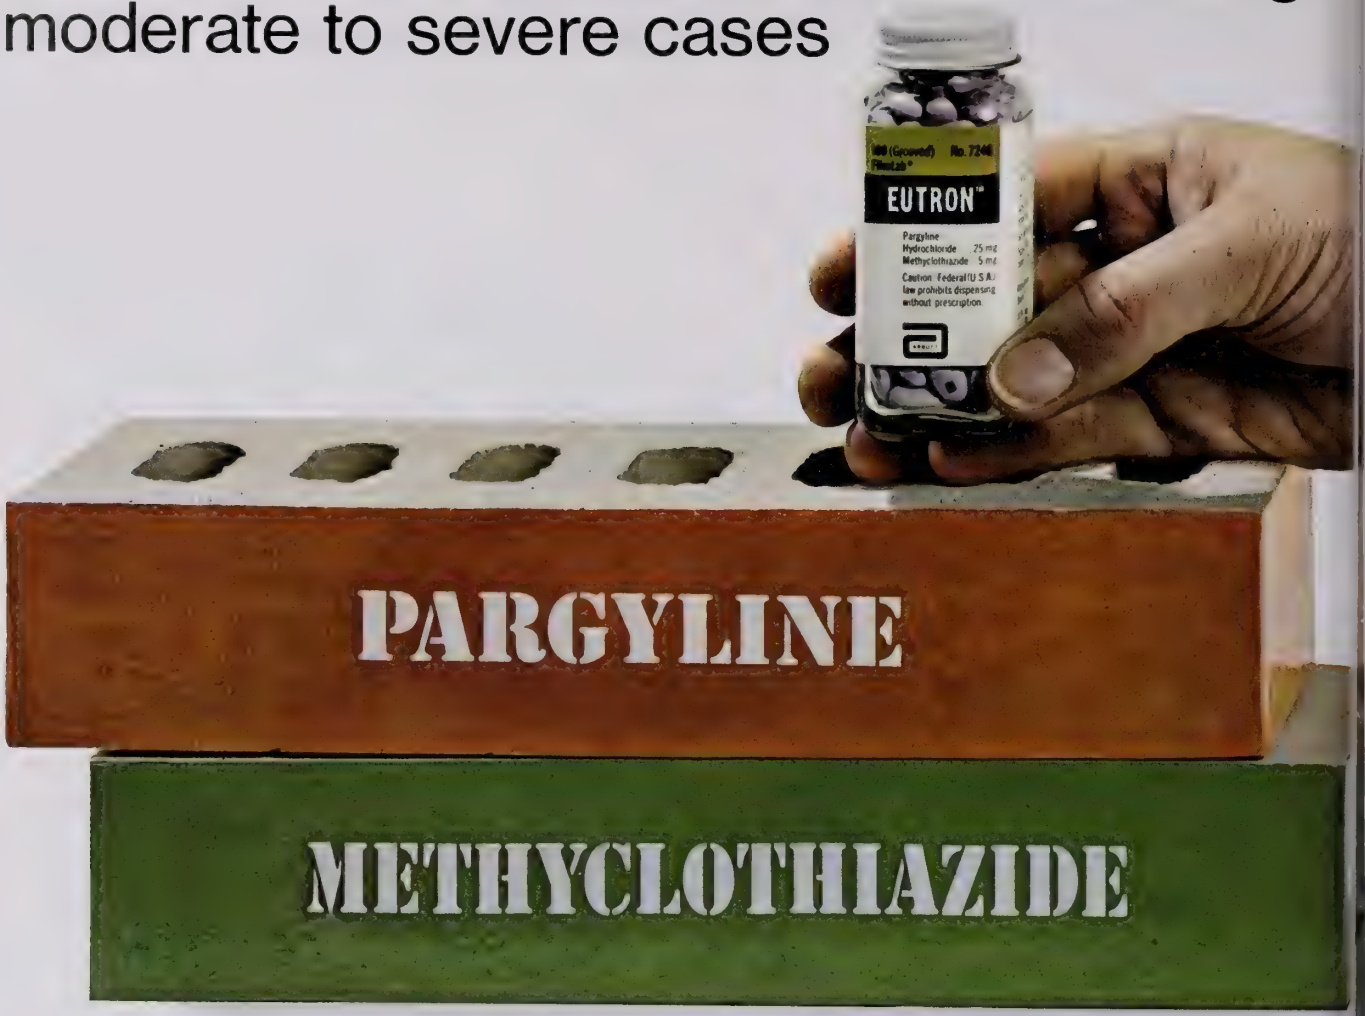
Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®

METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.



MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications: For treatment of patients with moderate to severe hypertension, especially those with severe diastolic hypertension. Not recommended for patients with mild or labile hypertension amendable to therapy with sedatives and/or thiazide diuretics alone. It is desirable to establish the dosage of Eutron by administering component drugs separately.

Contraindications: Pheochromocytoma, advanced renal disease, increasing renal dysfunction, paranoid schizophrenia and hyperthyroidism. Hepatic coma has been reported as consequence of hypokalemia with thiazide therapy. Until further experience is gained not recommended for patients with malignant hypertension, children under 12, or pregnant patients.

Concomitant use of the following is contraindicated: other monoamine oxidase inhibitors; parenteral forms of reserpine or guanethidine; sympathomimetic drugs; foods high in tyramine such as cheese; imipramine and amitriptyline, or similar antidepressants; methyldopa. 2 week interval should separate therapy and use of these agents.

Methyclothiazide is contraindicated in patients with known sensitivity to thiazides.

Warnings: Pargyline hydrochloride is a monoamine oxidase inhibitor. Warn patients against eating cheese, and using alcohol, proprietary drugs or other medication without the knowledge of the physician. When indicated, alcohol, narcotics (meperidine should be avoided), antihistamines, barbiturates, chloral hydrate, and other hypnotics, sedatives, tranquilizers, or caffeine, may be used cautiously in reduced dosage. In emergency surgery ¼ to ⅕ the usual dose of narcotics, analgesics, and other premedications should be used avoiding parenteral administration where possible. Carefully adjust dose of anesthetics to response of patient. Withdraw pargyline two weeks before elective surgery.

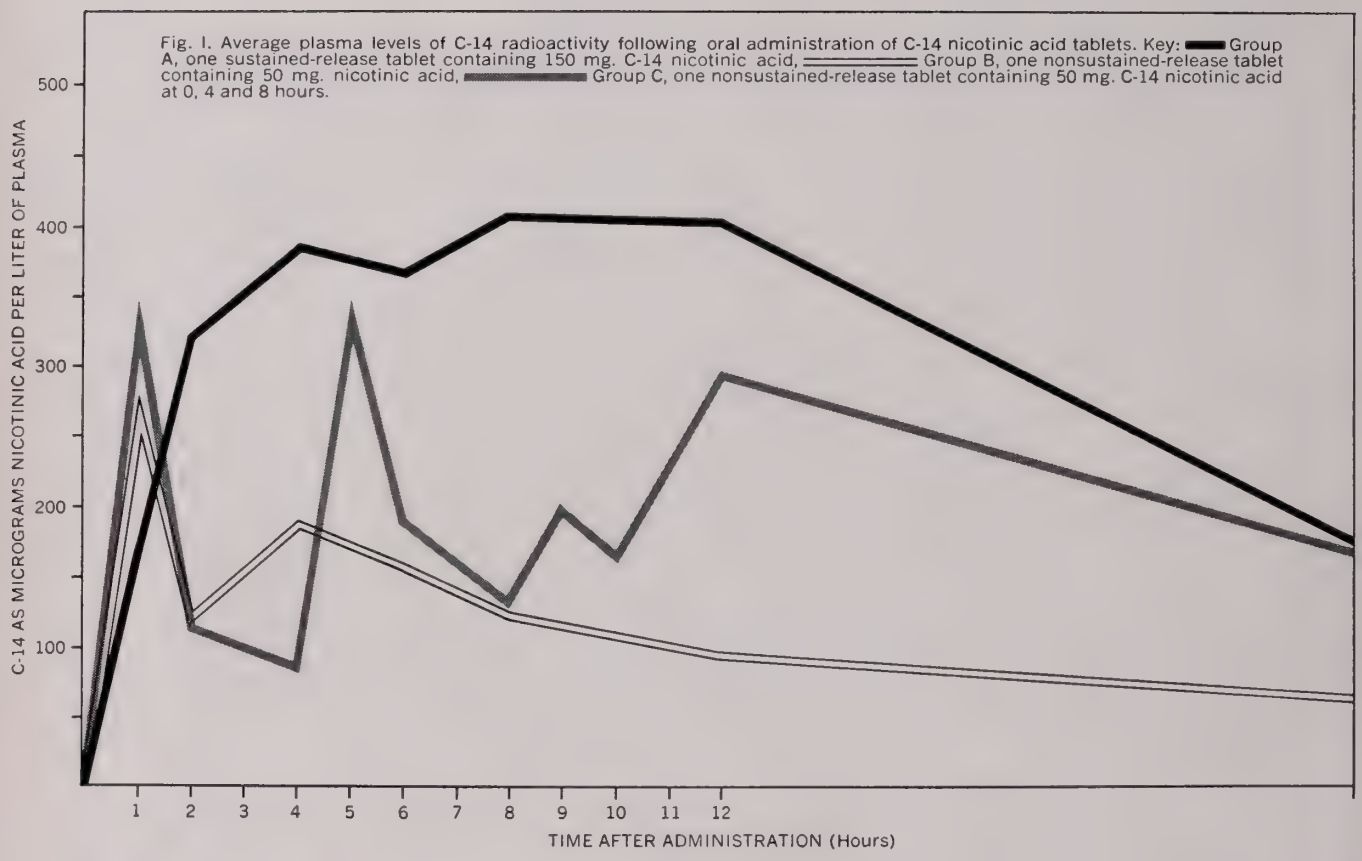
Warn patients about the possibility of postural hypotension. Those with angina or coronary artery disease should not increase physical activity with an improvement in well being. Pargyline may lower blood sugar.

Avoid use of enteric-coated potassium tablets, as these may induce serious or fatal small-bowel lesions consisting of stenosis with or without ulceration. These small-bowel lesions have caused obstruction, hemorrhage and perforation frequently requiring surgery. Medication should be discontinued immediately if abdominal pain, distension, nausea, vomiting or GI bleeding occurs. These products contain no added potassium salts and if added potassium intake is desired, dietary supplementation is recommended. Coated potassium tablets should be reserved for cautious use when adequate dietary supplementation is impractical. In patients with a history of allergy or asthma the possibility of sensitivity reactions should be considered.

Precautions: Measure blood pressure while patient is standing to determine antihypertensive effect. Use with caution in hyperactive or hyperexcitable persons. Such persons may show increased restlessness and agitation. Withdraw drug during acute febrile illness. Watch patients with impaired renal function for increasing drug effects or elevation of BUN and other evidence of progressive renal failure; withdraw drug if such alterations persist and progress. Use with caution in patients with liver disease. As with all new drugs, complete blood counts, urinalyses, and liver function tests should be performed periodically. With prolonged therapy, examine patients for change in color perception, visual fields and fundi. Also reported have been: blood dyscrasias including thrombocytopenia with purpura, agranulocytosis and aplastic anemia; elevations of BUN, serum uric acid, or blood sugar. Symptomatic gout may be induced. In surgical patients thiazides may reduce response to vasopressors and increase response to tubocurarine.

Adverse Reactions: Pargyline may be associated with orthostatic hypotension. Mild constipation, slight edema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence, delayed ejaculation, rash, and purpura have been encountered with pargyline. Hyperexcitability, increased neuromuscular activity (muscle twitching) and other extrapyramidal symptoms have been reported in a few patients with reduced cardiac reserve.

During intensive or prolonged therapy, guard against hypochloremic alkalosis and hypokalemia (especially the latter if patient is on digitalis). Observe all patients for signs of hyponatremia ("low salt" syndrome).



Reported thiazide reactions also include anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, and pancreatitis. Nocturia has been observed with the combination.

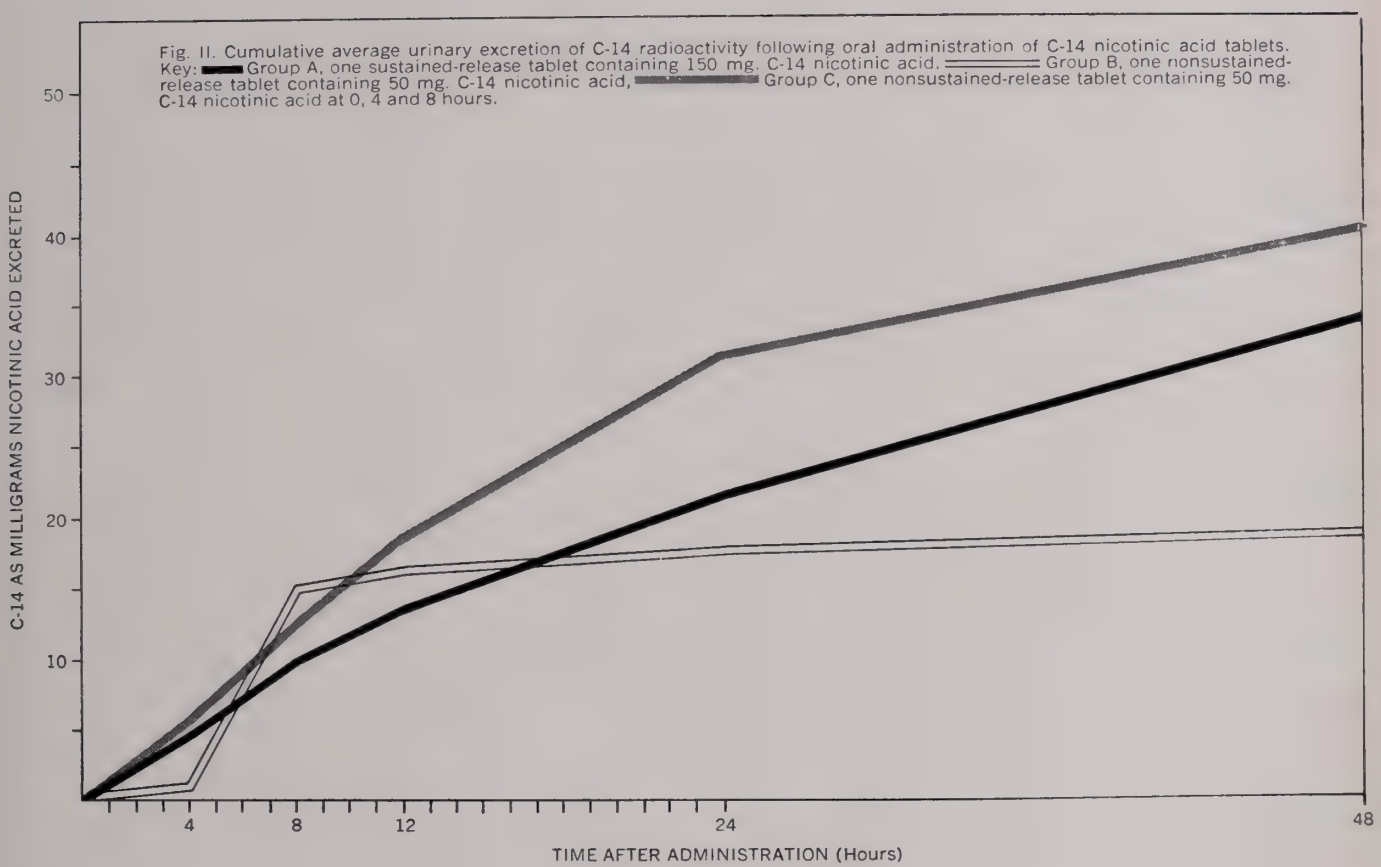
801438

ABBOTT

TM-TRADEMARK

Sustained circulatory, respiratory and cerebral stimulation for the a

(fewer absent doses by absent-minded patients)



Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Nickel Sensitivity

A 38-year-old woman was seen with an eruption involving both ear lobes (Figure). In addition, she had bilateral circumscribed eczematous lesions on the anterolateral aspects of both thighs. A tentative diagnosis of contact sensitivity to metal was made which was later confirmed by a patch test using a 5% aqueous solution of nickel sulfate. The patient was instructed to avoid earrings and to use protective pads under her garters. With these measures and a topical ointment the eruption promptly cleared.

This relatively simple case serves to illustrate a not too simple problem, that of contact sensitivity to metal. Of the metals producing such sensitivity, nickel is by far the most common. Nickel is usually present alloyed with other metals; some of the more common include alnico, duralium, nichrome, stainless steel and coin alloys. In years past this sensitivity was confined mainly to industrial workers, though today contact allergy to nickel is increasing in the general population and especially among women. Today nickel is found in an ever-increasing number of silver and gold articles with which people may come in

Figure

contact, such as jewelry, buckles, zippers, etc.

Although nickel dermatitis may occur anywhere on the body, certain areas are more common, such as ear lobes, neck, wrists and thighs. Clinically, nickel dermatitis often appears as a chronic eczema with lichenification resembling atopic or neurodermatitis. A characteristic of this dermatitis is its spread to distant areas without apparent direct nickel contact. At present this phenomenon has not been adequately explained.

Of the factors influencing nickel dermatitis, sweating is felt to be of prime importance. Sweat chlorides apparently are necessary in converting the metallic nickel to its soluble salts which in turn produce the sensitivity. In conjunction with sweat, pressure and friction are also important. This may explain the relative frequency of ear-lobe dermatitis secondary to nickel sensitivity in women who wear earrings. Articles containing nickel which are not worn under pressure or are worn on areas where sweating is minimal may cause little or no reaction. A frequently raised question is whether atopic individuals have a greater tendency to develop this type of reaction. To date the evidence does not support this contention. However, there does appear to be increased susceptibility in those individuals with dermatitic and soap-alkali-damaged skin. The mechanism of nickel sensitivity is not clearly defined, although studies tend to support the concept of delayed hypersensitivity in the absence of a hapten* allergic mechanism.

Once this sensitivity develops it tends to remain for many years. Therefore, management of the patient with nickel sensitivity consists of avoidance of direct contact with nickel-containing metals and the use of substitutes such as plastic garter clips. To date, desensitization attempts have been a failure. In addition to avoidance, the use of topical corticosteroid preparations is most helpful in clearing the eruption. Also, the use of a topical corticosteroid prior to the use of a nickel-containing article may be of help in mitigating the reaction.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Paradoxical

Two things fill the mind with ever new and increasing wonder—the starry heavens above me, and the moral law within me.—Immanuel Kant

Abstracts, Briefs and Commentaries

HOSPITALIZED MALE PATIENTS' REACTIONS TO A HEART ATTACK

Fifty employed male patients between the ages of 35 and 67 years admitted with a diagnosis of acute myocardial infarction were observed by nurses for emotional response to their illness and interviewed in depth by research psychiatrists. Of the patients 17 had suffered prior heart attacks or had a history of coronary artery disease; 29 were white-collar workers.

Individuals varied in their response to their illness according to their age. Fifty to sixty-year-old patients were more depressed than younger ones; contrariwise, every patient in his thirties was described by the nurses as jovial, unrealistically cheerful or even manic. Finally, patients less than 60 years of age more commonly resisted their treatment than those over 60.

These differences in emotional response appear to relate to general psychological attitudes. For example, there is evidence that young men are highly invested in being active and autonomous and stress their virility with external achievement and denial of weakness. On the other hand, men past 60 are generally more passive, have at least partially resolved their conflicts regarding prestige, and emphasize instead the importance of kindness and morality. Men in their fifties appear to have entered a period of crisis in which there is open conflict over the shift from the active orientation of youth to the passive position of later years. These men still cling to achievement autonomy goal, feeling they must push on, yet doubting their ability to do so. This struggle in the fifties suggests that enforced passivity due to the myocardial infarction may render these individuals susceptible to depressive illness.

Social class influenced the attitudes of the patients toward their illness. The white-collar class, while knowledgeable about their illness, were more skeptical than blue-collar patients regarding the adequacy of care. The white-collar patients were more uncertain and taxed the ingenuity of the medical and nursing personnel in allaying anxiety. The blue-collar workers accepted the authority of the physician and seldom asked the rationale of his treatment; hence these patients did not create difficulty for the staff and were easier to treat. These differences between white- and blue-collar workers became less noticeable in patients who had had two or more myocardial infarc-

tions. In these individuals anxiety increased, as did their skepticism and apprehension about their treatment.

SEDIMENTATION RATE

The rate at which a patient's red cells sediment often indicates whether that patient has disease. Although Fahraeus described the sedimentation test 46 years ago, precisely why red cells drop faster in the presence of disease remains a mystery. Increased fibrinogen and globulin levels, pregnancy, progestational drugs, anemia, and certain anticoagulants (oxalate and heparin) cause erythrocytes to fall more rapidly. But these factors explain only a few of the cases of increased sedimentation rate.

When red cells sediment faster than 100 mm. in one hour chances are the patient has a potentially fatal disease. Recently two Mayo Clinic physicians studied 263 patients with sedimentation rates of this magnitude, and 152 (58%) had malignancies. All but two tumors had metastasized. Curiously, only 11 patients had multiple myeloma (the one disease we usually associate with high rates), while 36 had lymphoma or leukemias. Only 66 patients (25%) had inflammatory diseases, while 22 had renal disease. In 14 individuals, the cause of abnormality was never determined. Tests which yielded the most diagnostic information included serum electrophoresis, bone marrows, x-rays of abdomen and lumbar spine, and BUNs.

Smallpox on the Frontier

Smallpox remained virulent, but vaccination was beginning to turn back the disease. To some cowpunchers the ounce of prevention seemed much too heavy. Dr. Henry F. Hoyt was vaccinating cowboys at Fort Elliott in the Texas Panhandle. Just as he was finishing up, the superintendent of the LIT Ranch walked into the store where the doctor was wielding the needle. He smoked a cigarette and yawned as he rolled up his sleeve. The doctor inserted the needle; the rancher looked at the tiny drop of blood oozing from his brawny arm and fell to the floor in a faint. The cowboys present allowed that such a "perfect shot" entitled the doctor to carve a notch on his gun.

Up in Montana, Dr. John Lewis Weitman of Great Falls was noted for his effective treatment of smallpox. His patients even recovered without scars. His explanation: "I get them so damned drunk they can't raise their arms to scratch the first three days."*

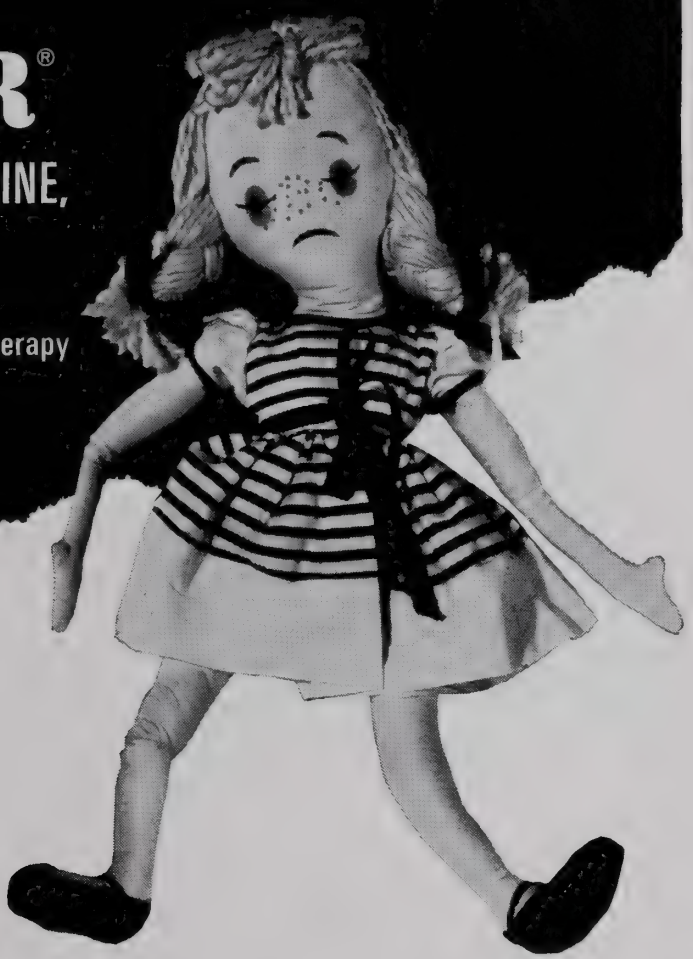
Qualifications

A doctor's character should be square, his knowledge round, his gall bladder large and his heart small.—Chinese proverb



If hypothyroidism leaves your patient feeling like this...

consider

LETTER®

(SODIUM LEVOTHYROXINE, ARMOUR) TABLETS

Synthetic Thyroid Replacement Therapy

Letter® provides all the advantages of the synthetically pure chemical sodium levothyroxine. Dosage is precise and potency is consistently uniform.

and

Letter® is micronized to provide maximum opportunity for full absorption and clinical response.

In addition Letter® is distinctively color coded with an identifying number stamped on each tablet to provide accurate dosage control.

Indications: Hypothyroid conditions. **Contraindications:** Thyrotoxicosis, acute myocardial infarctions unless associated with hypothyroidism. In hypothyroidism with hypoadrenalism coadministration of corticoids with LETTER® is recommended. **Precautions and Side Effects:** Excessive dosage may result in diarrhea, cramps, palpitation, nervousness, rapid pulse, sweating. If symptoms appear, discontinue medication for several days, then reinstitute at a lower level. Since myxedema patients with heart disease may suffer seriously from abrupt increases in dosage, caution should be exercised in adjusting dosage. **Dosage:** Generally, the initial adult dosage is 0.1 mg. daily. This may be increased in small increments every one to three weeks until proper metabolic balance is achieved. **Available:** Bottles of 100 tablets, in six potencies: 0.025 mg. (violet), 0.05 mg. (peach), 0.1 mg. (pink), 0.2 mg. (green), 0.3 mg. (yellow), and 0.5 mg. (white).

ARMOUR PHARMACEUTICAL COMPANY • CHICAGO, ILLINOIS

Phenaphen® with Codeine

the only leading compound analgesic that calms instead of caffeinates

Each capsule contains:

Phenobarbital (¼ gr.)	16.2 mg.
(Warning: may be habit forming)	
Aspirin (2½ gr.)	162.0 mg.
Phenacetin (3 gr.)	194.0 mg.
Hyoscyamine sulfate	0.031 mg.
Codeine phosphate	¼ gr. (No. 2), ½ gr. (No. 3), 1 gr. (No. 4)
(Warning: may be habit forming)	

Contraindications: Hypersensitivity to any ingredient.

Precautions: As with all phenacetin-containing products, avoid excessive or prolonged use.

Side Effects: Side effects are uncommon—nausea, constipation, and drowsiness have been reported.

A-H-ROBINS

A. H. ROBINS CO., INC., Richmond, Va. 23220

For your impatient cold patients

Two sprays from NTZ Nasal Spray—and nasal congestion, rhinorrhea, sneezing are reduced for *immediate* comfort for patients with colds.

NTZ is more than a simple vasoconstrictor. It contains:

Neo-Synephrine® **(brand of phenylephrine) HCl 0.5 per cent,** the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction on contact.

Thenfadil® **(brand of thenyldiamine) HCl 0.1 per cent,** topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® **(brand of benzalkonium, as chloride, refined) 1:5000,** antiseptic preservative and wetting agent to promote penetration and spread of the formula.

NTZ is well tolerated. Used in a cold it may help prevent sinusitis by opening sinus ostia and permitting drainage. It may also be used in sinusitis to help establish drainage.

The spray is best used twice, the second a few minutes after the first, repeated every three or four hours as needed. NTZ is for temporary relief of nasal symptoms, and overdosage should be avoided.

Supplied: NTZ Nasal Spray, plastic squeeze bottles of 20 ml.; NTZ Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTZ®
NASAL SPRAY

relieves
nasal symptoms
on contact

a puzzle of antacid complaints

Mylanta®

aluminum and magnesium hydroxide *plus* simethicone

a solution to peptic ulcer distress

Effective neutralization—
with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

Concomitant relief of G.I. gas distress—
with the proven[1] defoaming action of simethicone.

Prolonged acceptance confirmed—
in 87.5% of 104 patients after a total of 20,459 documented days of therapy.[2]

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg.
Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

Book Reviews

Books are lighthouses erected in the great sea of time.—E. P. Whipple

DIABETES MELLITUS: DIAGNOSIS AND TREATMENT. Volume 2. Editors: George J. Hamwi, M.D. and T. S. Danowski, M.D. Prepared under the auspices of the Committee on Professional Education of the American Diabetes Association, Inc. New York, N. Y., 1967.

This 240-page book addresses itself to the practicing physician in clear and concise language. The organization of the material is excellent. Research data are used whenever they may have a bearing on the clinical management of the diabetic patient. The book is easily read and understood.

The classification of secondary diabetes is clear, brief and lucid, but it should include pheochromocytoma along with hyperpituitarism, Cushing's syndrome, and the hyperthyroid states. The emphasis on the influence of exercise in the treatment of diabetes is excellent. One would wish that the Somogyi-effect as a consequence of imprudent insulin therapy had received more emphasis.

The discussion of the treatment of diabetic acidosis and coma might have gained more practical usefulness if it had been demonstrated by means of a detailed sample protocol. Finally, the insulin dosage recommended for the treatment of diabetic acidosis and coma is high enough to result in life-threatening hypoglycemia within the first 24-36 hours of therapy.

With the exception of the just cited items the book is a valuable guide for the day-to-day treatment of the diabetic patient, as well as for the management of emergencies.

H. H. Zinneman, M.D.
Minneapolis, Minnesota

GREAT IDEAS IN THE HISTORY OF SURGERY—Leo M. Zimmerman and Ilza Veith. 547 Pages. Dover Publications, Inc., New York. 2nd Revised Edition.

This book is a large compendium emphasizing the ideas which have generated progress in the science and art of surgery rather than dealing with the details of biography. The biographical development is, of course, not eliminated but takes its proper place in the development of background for the ideas developed by the great men in surgery.

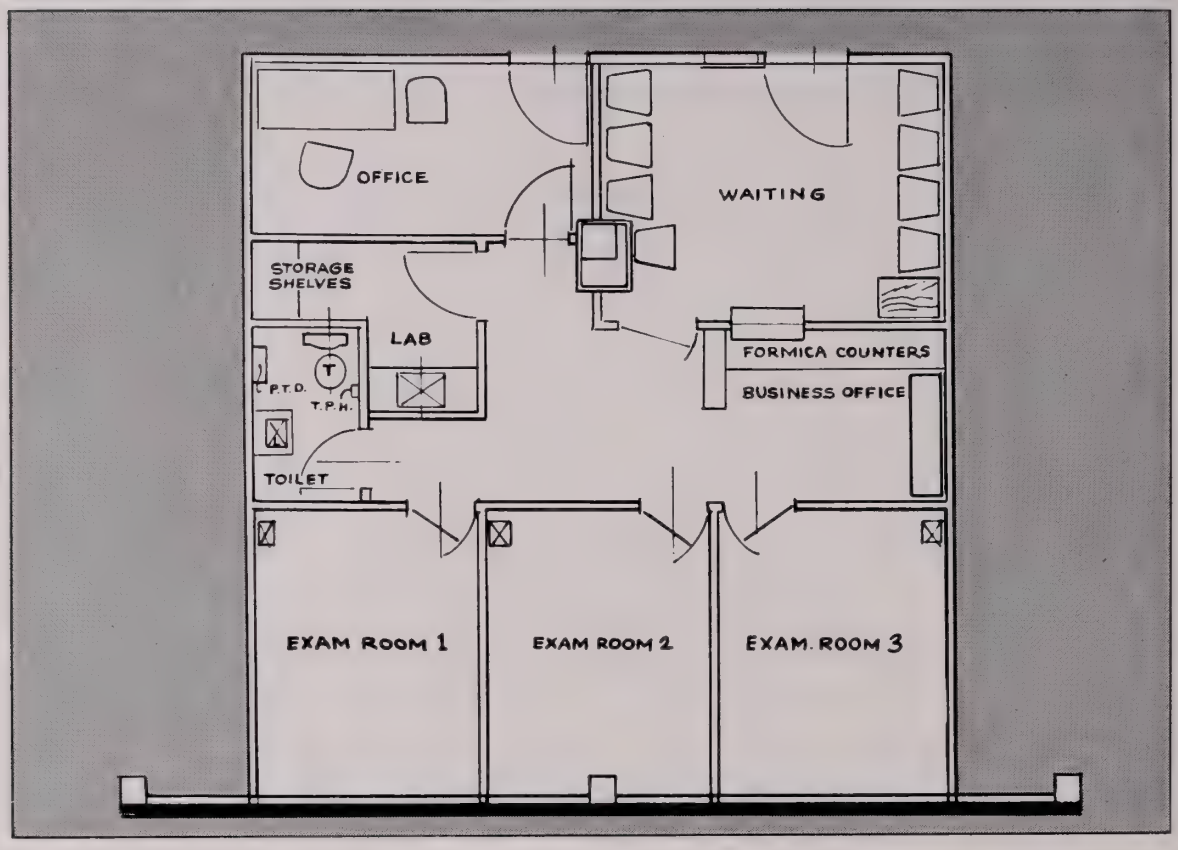
The reader will undoubtedly be intrigued by the originality of numerous relatively unknown contributors to the advancement of medicine. The "great" men of surgery are properly developed, and it is very gratifying reading to realize the multitude of ideas which have made these men great.

If a reader indulged in no more effort than skip reading, he would discover the very ancient origin of many significant contributions which originate the practices of today. A more careful reading will demonstrate the rebirth of many great ideas that have been forgotten or have fallen into disuse for prolonged intervals.

One could recommend this as a baseline or background reading to the Journal of the History of Medicine.

This is a highly commendable work which deserves to be on the shelf of every surgeon, whether he desires to study it intensively or use it for entertainment as occasional pickup reading.

J. H. Strickler, M.D.
Minneapolis, Minnesota



PULMONARY INSUFFICIENCY AND RESPIRATORY FAILURE—Giles F. Filley, M.D. Cost: $7.00. Lea & Febiger, Washington Square, Philadelphia, Pa.

This 162-page monograph provides the physician with an excellent, concise review of essential clinical pulmonary physiology and the symptoms related to a disturbance of the normal ventilatory and diffusion function. Nicely presented is the explanation of the disturbed ventilatory-pulmonary blood flow ratio, hypoxemia, shallow breathing and lung compliance.

In addition, the practical aspects of the recognition of pulmonary insufficiency, the treatment thereof, and the concept of a "respiratory care unit" merit wide application in every hospital and by every physician. The bibliography is extensive and pertinent if further reading is desired. The illustrations (28) are well done and easily interpreted.

This book is thoroughly enjoyable reading. Certain books are the type to keep close at hand for those precious 15-20 minutes of relaxation and learning, at the office, home, or hospital. Dr. Filley and Staff have assembled a monograph to be read and reread—a real pleasure to review.

J. T. Grismer, M.D.
Minneapolis, Minnesota

b.i.d.

The sensible schedule that covers the patient day and night

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, then you know why b.i.d. DECLOMYCIN is considered to be a sensible dosage schedule.

The maintenance dosage of DECLOMYCIN can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

The b.i.d. dosage of DECLOMYCIN gives you the comfortable assurance that the patient is well-covered, *day and night.*

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective; because of high serum binding and slow renal clearance. And if there's a broader susceptibility pattern of organisms, we've yet to see it.

There is no need to give higher daily dosage than 300 mg b.i.d., except in venereal diseases and Eaton Agent pneumonia.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Lederle

Prescribing information on next page.

b.i.d. The sensible schedule that covers the patient day and night

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

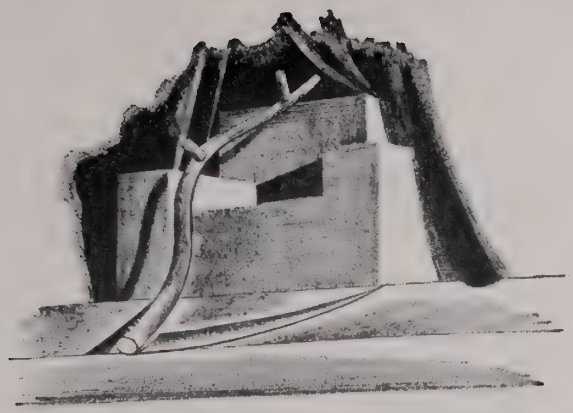
Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occure. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes. A rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth— dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm. given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.



Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg. of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg. every 6 hours for a minimum of 4 doses or 300 mg. every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg. every 6 hours or 300 mg. every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg. in 3 divided doses for six days.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, N.Y.

In Memoriam

Gone before to that unknown and silent shore.—Lamb

CARL O. KOHLBRY, M.D.

Dr. Carl O. Kohlbry, 70, Duluth physician and health director of the Board of Education, died November 29. Born in St. Louis, Missouri, he was a graduate of Washington University Medical School. He came to Duluth in 1921 and was engaged in private practice until 1954 when he became health director of the board of Education.

He was a member of the St. Louis County Medical Society and the American Medical Association and a Life Member of the Minnesota State Medical Association.

He is survived by his wife, two sons and a daughter.

ALFRED L. VADHEIM, M.D.

Dr. Alfred L. Vadheim, who practiced medicine in Tyler, Minnesota, for more than fifty years, died November 26, at the age of 83. He was born in Garretson, South Dakota, graduated from the University of Minnesota in 1909, and went to Tyler the following year. Early in his career, he organized and equipped Tyler's first 5-room hospital.

Dr. Vadheim was a member of the American College of Surgeons, the Lyon-Lincoln County Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife, two daughters, and three sons, Dr. James Vadheim of Tacoma, Washington, Dr. Lewis Vadheim of Pomona, California, and Dr. Robert Vadheim of New York City.

JOHN L. SHELLMAN, M.D.

Dr. John L. Shellman, formerly of St. Paul, died on November 23 in Palisades, California. He was 91. Born in Fergus Falls, he graduated from the University of Minnesota Medical School in 1903. He practiced on the Mesaba Range at Nashwauk and for more than twenty-five years in St. Paul.

He was a member of the American Medical Association, American College of Surgeons, American Academy of Ophthalmology and Otolaryngology, Minnesota Society for the Prevention of Blindness and the Ramsey County Medical Society. He was a 50 Club and Associate Member of the Minnesota State Medical Association.

He is survived by his wife and daughter. Dr. Joseph F. Shellman of St. Paul is his brother.

RAYMOND M. EPPARD, M.D.

Dr. Raymond M. Eppard, 73, Cloquet surgeon, died January 1. He was born in Racine, Minnesota, and received his medical degree from the University of Minnesota.

He was a member of the American Medical Association, the Minnesota State Medical Association and the St. Louis County Medical Society.

He is survived by his wife, two daughters and a son.

CHARLES BISHOP WILL, M.D.

Dr. Charles B. Will, 56, International Falls physician, died December 27, while shoveling snow in the driveway at his home. Born in Bertha, Dr. Will practiced in International Falls since 1955. He was a graduate of the University of Minnesota Medical School.

Dr. Will was past president of the Upper Mississippi Medical Society; past president of the Range Medical Society; a council member of the Minnesota Academy of General Practitioners; medical representative of the Falls Memorial Hospital Board, and a member of the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife and a daughter.

LEROY J. HOLMBERG, M.D.

Dr. LeRoy John Holmberg, 92, died December 7 in Canby. Born in LaCrosse, Wisconsin, Dr. Holmberg graduated from the University of Illinois Medical School. He practiced medicine in Cashton, Wisconsin until 1908 when he moved to Canby where he practiced for fifty-five years, retiring in 1963.

He served as a medical officer during World War I; a past president and secretary-treasurer of Camp Release District Medical Society; served as surgeon for the Chicago and North Western Railroad, was a member of the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association. He is survived by his son.

OLIVER M. PORTER, M.D.

Dr. Oliver M. Porter, 90, Atwater physician, died September 7. He received his medical degree from the University of Minnesota and was licensed in 1905 to practice medicine.

Dr. Porter was a member of the American Medical Association and the Kandiyohi-Swift-Meeker County Medical Society and an Associate and 50 Club Member of the Minnesota State Medical Association.

Tandearil®, oxyphenbutazone, 100 mg. tablets

Indications: Osteoarthritis, rheumatoid arthritis, rheumatoid spondylitis, psoriatic arthritis, gout, painful shoulder (peritendinitis, capsulitis, bursitis and acute arthritis of that joint), acute superficial thrombophlebitis, severe forms of a variety of local inflammatory conditions. (In inflammatory conditions not involving prolonged or fatal disease, use only when severity of condition balances potential toxicity.)
The drug has no significant uricosuric action but is of value only in the treatment of acute gouty arthritis.
Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently.
Warning: Tandearil is an analog of phenylbutazone; sensitive patients may be cross-reactive. If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.
Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make regular blood counts. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.
Adverse Reactions: The most common are nausea, edema and drug rash. Swelling of the ankles or face may be minimized by with-

"Pain Break" for an osteoarthritic. Tandearil can ease it.

At 46, her knees still look good on the outside. But inside, there may be the familiar picture of osteoarthritis.

If aspirin doesn't help, Tandearil often will. Pain and stiffness begin to ease up in 3 or 4 days. You can often maintain response with a daily dose of only 1 or 2 tablets.

Of course, Tandearil is not for every osteoarthritic. Select your patients carefully and follow them in line with the Contraindications, Precautions, Warning, and Adverse Reactions listed below.

But for many aspirin-stubborn osteoarthritics, let Tandearil ease the unwelcome pain breaks of osteoarthritis.

Tandearil®
oxyphenbutazone

holding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately after meals or with milk to minimize gastric upset. Mild drug rashes frequently subside with reduction of dosage. However, rash accompanied by fever or other systemic reactions usually requires withholding medication. Purpuric rash has also been reported. Agranulocytosis or a generalized allergic reaction similar to a serum sickness syndrome may occur and require permanent withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Osteoarthritis: Initial: 3 to 6 tablets daily in divided doses. It is usually unnecessary to exceed 4 tablets daily. A trial period of 1 week is adequate to determine response; in the absence of a favorable response, discontinue. Maintenance: An effective level is often achieved with 1 or 2 tablets daily, do not exceed 4 daily. 6562-VI(B)R2

Nothing else I've tried seems to work, so I decided to give you a crack at it.

Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

With Novahistine LP tablets and Novahistine Singlet tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.

Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever.

Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.

Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.

Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

DOW PITMAN-MOORE DIVISION OF THE DOW CHEMICAL COMPANY, INDIANAPOLIS

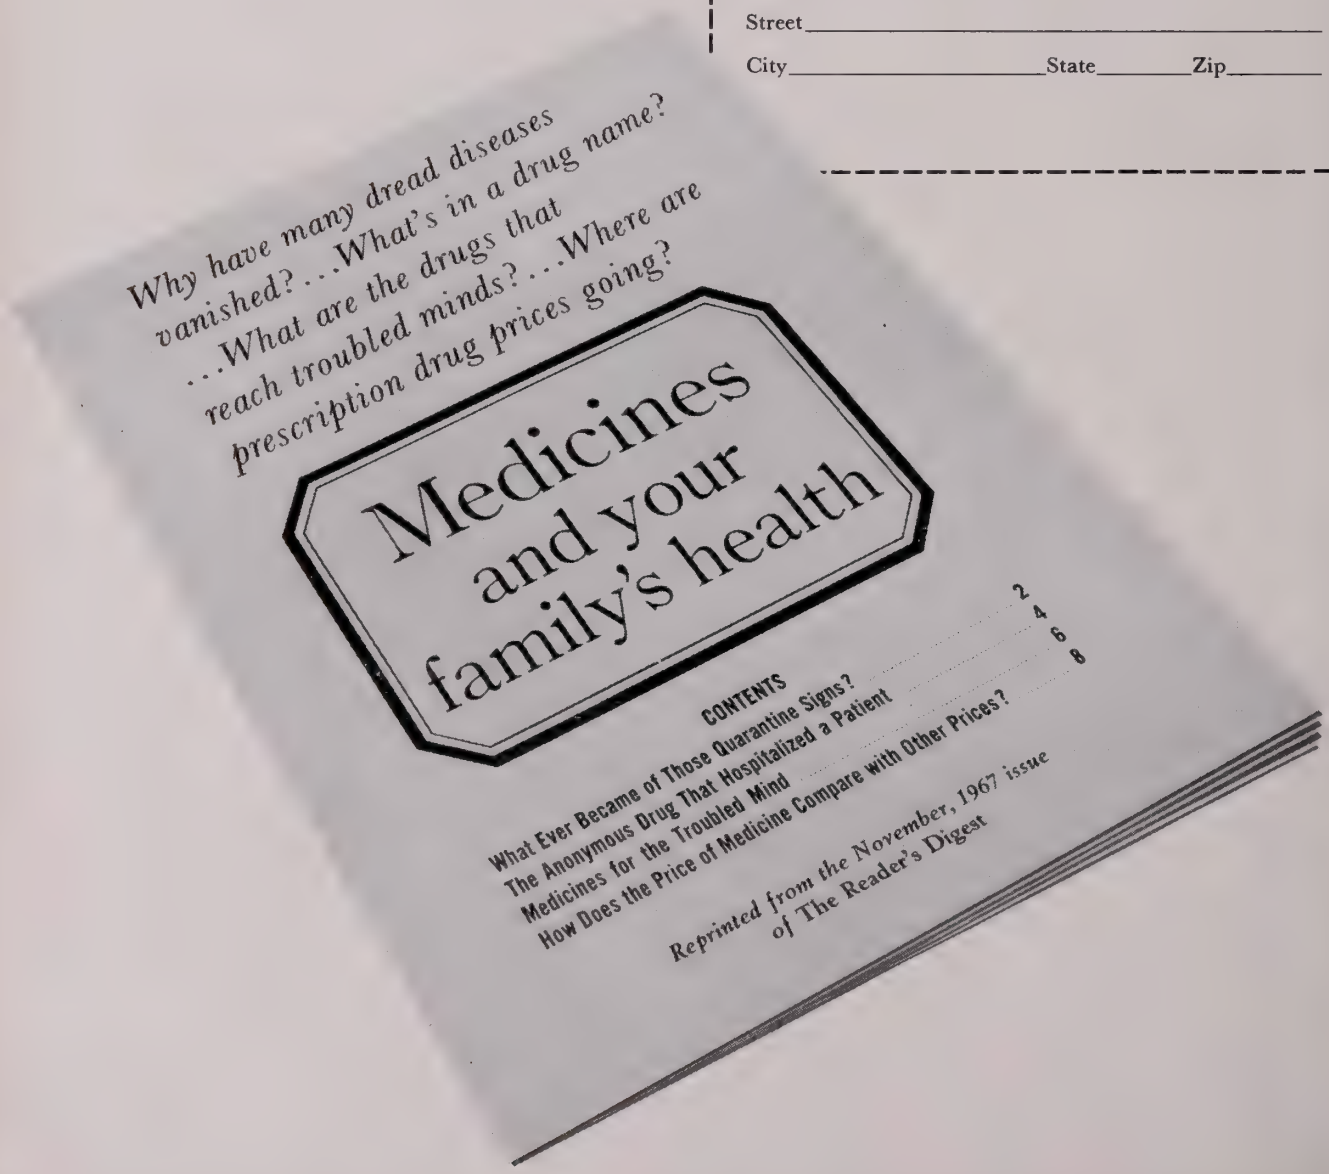
Dear Doctor:

Wouldn't you like your patients to learn more about the contributions made by the world of medicine to their welfare? So that they can better appreciate the efforts of the health team to keep them in good health?

To tell the stories of medical and pharmaceutical advances to people throughout the country, the Pharmaceutical Manufacturers Association is sponsoring a unique "magazine within a magazine." It is called *Medicines and your family's health* and the first issue appears in the November *Reader's Digest.*

We would like to send you 50 free reprints of *Medicines and your family's health* for use in your reception room. Your patients will find the articles in this issue factual, educational and of immediate personal interest.

Just fill out the coupon below and send it to us.



Order Desk
Pharmaceutical Manufacturers Association
1155 Fifteenth St., N.W.

Paranoid Wife Syndrome

DONALD C. CARTER, M.D.*
Columbia, Missouri

A PATIENT with this syndrome complains of low energy and has an overlay of neurotic depression. She initially perceives her problem as a medical one, but when careful examination shows no organic disorder, she exhibits more neurotic complaints associated with the persistent view that her husband is somehow to blame.

In our series of 32 intensively treated cases, she has usually been married five to ten years, and may have as many children. Her low psychic energy manifests itself by a syndrome of clinging dependency, a self-critical, depressed mood, and the conviction that the dependency claims and demands of husband and children are inundating. She believes that if she were loved more sincerely and given more time or indulgent attention a rise in energy would occur. Seldom are objective reasons for the low energy recognized by the patient herself. The psychic delusion of a socially deprived and exploited life quickly becomes the topic of conversation with such a patient.

The experienced practitioner knows that variations in women's energy are frequent and difficult to explain. His initial approach is usually conservative and supportive; and he anticipates a natural resolution. The case becomes an office problem only when usual measures do not help and a tranquilizer or energizer prescription is rejected as merely temporary in effect. He may then decide to spend more time listening to the patient in order to get to the bottom of the problem. With faith in the rationality of the human mind, he awaits his chance to formulate what is wrong and offer corrective counsel. In the more severe forms of this disorder his efforts are doomed to failure, not because he is a poor counsellor or is unsympathetic, but because the natural course of the disorder is a progressive one. It begins with energy depletion revolving around feminine duties of home-making and child-rearing and proceeds to the gradual precipitation of blame-shifting paranoid delusions,

*Assistant Professor of Psychiatry, University of Missouri.

centering around the basic idea that the husband is at fault. This clarification may take several months of follow-up visits, during which the patient may vary the degree of the blaming process or even abandon it spontaneously for many months for no obvious reason.

Medical History:

The general medical history of these female patients often contains several recent humiliating features. Dexedrine addiction may have carried them for a while, but now abuse or intolerance makes discontinuing it mandatory. Secondly, an unfortunate obstetrical experience may have resulted in a feeling of failure. Thirdly, a child may have been seriously ill, the mother perceiving the need for medical care only dimly at first, later with greater clarity but much self reproach. Problems in obstetrical and pediatric care associated with difficult labor are common examples of humiliation to a woman's self esteem, but are not generally recognized as such.

The Husband:

As treatment progresses, the physician feels it important to get the allegedly "depriving" and "persecutory" husband in for a conference and confrontation. This interview has many predictable features and a characteristic course. The husband is usually a remarkably passive fellow who finds numerous excuses not to come in. When he finally does he listens quietly, giving the impression of imperturbability as his chief character trait. But good rapport and direct confrontation will eventually bring a response: he notes that he could be a better husband if only she were a better wife.

The Wife:

He then recites a litany of wifely duty derelictions on her part: for example, that she is tired and irritable much of the time; that housework is neglected; that children are poorly cared for; that meals are irregular, and that sexual intercourse is refused him more often than not. When the physician says that she performs poorly due to low psychic and somatic energy he finds this explanation falling on deaf ears.

A serious and empathic search from the husband's point of view elicits disbelief that womanly performance has anything to do with her state of mind. He believes that his wife should perform well if only told to do so. He presents the idea in a moral-intellectual manner, ignoring her emotional needs as unworthy of consideration, an attitude strongly psychotogenic for her already weakened state. For him to quote religious and other patriarchal authorities to support his point of view is also futile.

Follow-up:

Additional interviews may get him to soften this rejecting and demanding attitude and concede that she may have a point. He may then reveal that she blows up into psychotic rages when he does certain things he likes and she hates; but there are also rages for which he cannot recognize a provocation. The situations which provoke her are self-indulgent pleasures which he is reluctant to admit or renounce. Trial runs of giving them up, however, may help her, if she can immediately respond with more enthusiastic energy and housework output. This bears out the idea that he will get further by cooperation than by vindictiveness.

Depending on the length and severity of the psychotic trends operating in her personality, healing results may be apparent at this point. The remainder of this paper speaks to the more severe cases where erratic performances continue to disrupt and destroy the family's biosocial functions. Then the husband returns to say that she remains hostile and critical, rejecting his best efforts, and that nothing he does helps.

Marriage Counseling:

At this point the physician may despair and refer the case to a marriage counselor or to the Community Mental Health Center. Even when these consultant resources are available and the family cooperates, the family physician continues to have much responsibility. Chemotherapy and advice about the possibility of suicide or the feasibility of divorce are examples of his responsibility.

Indications for Poor Prognosis:

Severe ambivalence in the patient's feelings toward the husband may paralyze her using any advice or coming to any decision on how

to help herself. This commonly-found mental symptom is the worst one in the long run and responds at best only partially to treatment.

A complete inability and refusal by the husband to give up the self indulgences which interfere with his function as a father at home is commonly exemplified in our series by long hours of unnecessary over-work, which he claims gives his life the energy and meaning which his wife has failed to provide. Therefore her needs come second. He also fails to recognize his obvious flight from her hostility. When he is pressed to correct this point, he again argues on the irrationality of her needs.

Sexual impotency reaction in the husband to the wife's high level of hostility bodes a bad outcome.

Perception by her that the impotency is punitive and, further, that it proves her not to be a desirable woman again worsens the relationship.

Sadistic and masochistic fights with beatings may occur, the descriptions of which often defy our imaginative credulity.

The gradual psychotic reorganization of the conflict within the wife's personality, in which she develops a psychologically aversive reaction to all the husband's gratifications, only completes the alienation which has often been operative from the first in more hidden or partial forms.

Another somewhat different tactic is a motherly, indulgent attitude toward the patient by the spouse, also often interpreted to mean that she is a failure as a mother and homemaker. This reaction on her part is often a further alienating one for her women friends who may have been supportive up to this point. They see the husband's behavior only for its conscious intent, whereas she registers a deeper, more subtle message.

In general, anything which makes her feel less feminine is a potentially worsening factor.

Indications for a Good Prognosis:

Generally helpful is any set of experiences or limiting circumstances which curtails those facets of the husband's behavior perceived by the wife as an affront.

A direct restructuring of the marital relationship so as to change the malignant combination of the wife's great expectations and the husband's cool passive denial of their existence would be an ideal goal. If marital counseling can resolve this impasse, then her symptoms diminish.

Her employment outside the home, where working relationships are inspiring and her opinions influential, is generally helpful.

Often a change for the better results when the husband disavows the attitude that womanly performance is simply obedience to the wise directives of a man. This attitude applies to masculine performance and should not be mistakenly transferred to the feminine sphere.

Outcome:

Suicide is a definite possibility when psychologically paralyzing ambivalence is severe and the woman's anger internalized. Additional motives for this drastic step are two-fold: the patient may be so well structured in her either-or thinking that she simply cannot see any relief other than oblivion; or she may want to prove to the world that her husband was so impossibly selfish that this stark alternative was preferable. When serious suicide attempts are repeated, vigorous intervention by family, pastor, or attorney is necessary. An ambivalent component of the patient's personality will, of course, resist any maneuver by others.

Divorce for Social Reasons:

Divorce is often an answer that the patient herself arrives at when she finds solid support outside the illusory props of her miserable status quo. I have seen welfare agencies and other counselors recommend divorce, usually based on the extent of social indecency involved. But this is an example of a social reason, not a psychiatric one.

Divorce for Psychiatric Reasons:

Diminution of the rage symptom by the physical absence of the spouse should be well demonstrated. A trial absence of at least 90 days will differentiate the wife capable of sustained logic. Many an inadequate wife will ambivalently switch from hate to loneliness on about the 45th day and then begin to deny the existence of the previous problems. Experi-

ence in dealing with loneliness is necessary for her to avoid humiliating repetitions and further damage to her self-esteem.

When she appears able to rechannel the energy of her rages into constructive outlets of work and family guidance, she then has a greater opportunity for self-fulfillment.

When she appears able to accept the idea of self-support, which is sure to become necessary eventually, divorce is a way of ending the degrading and hostile dependency and therefore a good thing for her.

When she appears able to relate to another man in a genuinely complementary way, showing little or no aversive reaction to whatever his narcissistic character traits may be, the possibility of a successful second marriage is good.

When supportive relatives are available or when the local welfare or other agency can be supportive without being rebuffed by the hostility in her dependency, then she should choose this escape.

The physician's role may not necessarily be the working out of these alternatives, but he should be able to clarify them for other interested parties. He should guide the patient to adequate emotional support from others, help provide this himself, and work to protect her from any further humiliation to her womanly self-esteem. And last, but not least, he should evaluate and revise these criteria. Careful documentation of his successful cases can be very reassuring for managing future cases.

He may see his role as chemotherapeutic alone, which may be sufficient in some cases. Phenothiazines and antidepressants may control the rages and the physiologic equivalents, allowing the patient to evade the paranoid stage and, in a crippled and unresolved way, live with her problem. Supportive psychotherapy often can do the same thing, thereby postponing the day of reckoning until a more favorable time.

Medical Men on Postage Stamps

William J. Mayo (1861-1939) and his brother, *Charles H. Mayo* (1865-1939), surgeons who founded the Mayo Foundation for Medical Education and Research in affiliation with the University of Minnesota at Rochester, Minnesota, appear on a United States postage stamp issued in 1964. Their heads as shown on the stamp are from a sculpture by James Earle Fraser.

Leopold Auenbrugger (1722-1809) was a Viennese physician, medical writer, and discoverer of chest percussion as a diagnostic procedure, the principle of which occurred to him from having thumped on wine casks in his father's inn to determine the quantity of liquid therein. In his honor Austria issued a postage stamp in 1937.

An Ancient Tranquilizer

Consider the course of the stars as if you were driving through the sky and kept them company. Such contemplations as these scour off the rust contracted by conversing here below.—Marcus Aurelius

(one tablet daily)

Regroton®

chlorthalidone 50 mg., reserpine 0.25 mg.

Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Regroton should be used in pregnant patients or in women of childbearing potential only when, in the judgment of a physician, its use is deemed essential to the welfare of the patients; adverse reactions (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.
Precautions: Antihypertensive therapy with Regroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue Regroton therapy two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, Regroton should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000. (B) 46-600-B
For details, see complete Prescribing Information.

Tissue's healing nicely. Yet anxiety slows his steps toward recovery.

By helping overcome anxiety and tension which can thwart the convalescent's progress, Equanil® often may play an important role in medical and surgical aftercare.

Indications: For use in management of anxiety and tension occurring alone or as accompanying symptom complex to medical and surgical disorders and procedures. Though not a hypnotic, fosters normal sleep through antianxiety and related muscle-relaxant properties.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

INTERNIST WANTED: Central Wisconsin city of 35,000 needs internist badly. Solo practice, association with small group or large clinic available. Contact G. H. Brister, M.D., Medical Arts Bldg., Wausau, Wisc.

GENERAL SURGEON, Certified, part or full-time association in multi-specialty clinic. Alfred F. Anderegg, M.D., 645-5851, 2500 Como Ave., St. Paul, Minn.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

WANTED: General practitioner, to join two G.P.'s well established in north central Minnesota community, 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital, all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. WRITE MINNESOTA MEDICINE—381; 375 Jackson, St. Paul, 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

FOR SALE—GASTROSCOPE: Eder-Palmer Trans Esophagoscopic Gastroscope, Model 5-C, Flexible 9 mm diameter by 86 length. Cost $1,086, used very few times. Sell for $475. Write or call Mankato Clinic, Ltd., 501 Holly Lane, Mankato, Minnesota 56001.

MORGAN, MINNESOTA, Wants a General Practitioner. Opportunity to take over a well established practice. Physician recently retired after practicing here for 33 years. Progressive community in the best rural area of Southern Minnesota. New medical clinic building just completed. Call or write M. L. Kuhn, Morgan, Minnesota. Tel. Morgan #73 or #99.

PSYCHIATRIC RESIDENCIES: Approved three-year progressive program in Metropolitan Detroit area. University associations. Teaching staff of Board men, psychoanalysts, professors, outstanding visiting lecturers. Active Research. Modern Physical plant. Salary $8,978; $9,405; $10,213. Five year career program $10,213 to $18,507. Salary increase expected in July. Liberal Civil Service benefits. General Practitioners completed internship four years ago may be eligible for NIMH stipends of $12,000 per year. Write, Director of Education and Research, Northville State Hospital, Northville, Michigan 48167.

SENIOR PARTNER retiring and wish another physician to join busy general practice. L. T. Winninger, M.D., 601 Baltimore St., Waterloo, Iowa 50702.

PHYSICIAN WANTED: G.P. with additional surgical and OB experience—desired to associate with two G.P.'s with similar experience in large, well established practice in Central Minnesota. Hospital accredited, 300 bed, open staff, complete services. Salary leading to partnership. Adequate housing in area. Send background information, professional and personal to: MINNESOTA MEDICINE-283, 375 Jackson, St. Paul 55101.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

TWO MAN PARTNERSHIP desires a third in general practice. Good office set-up in growing industrial town of 15,000 in Southern Minnesota. Excellent hospital, school systems and recreational facilities. One hour on freeway to downtown Minneapolis. Contact: Drs. Floersch & McEnaney, 127 West Vine Street, Owatonna, Minnesota 55060.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

FOR RENT Medical Clinic: Fridley. Suburb of Minneapolis. Next to Holly Shopping Center. One half mile from Unity Hospital. Six examining rooms. X-ray and dark rooms. Laboratory and emergency rooms. Large reception and bookkeeping facilities. Excellent opportunity and location in city of 30,000. Call 522-1188, or write Richard J. Trezona, D.D.S., 2503 Lowry Avenue North, Minneapolis, Minnesota 55411.

UNUSUAL OPPORTUNITY Internist or GP interested in internal medicine. Small multispecialty group midwest city of 8000, population area 50,000. Accredited hospital. Modern Clinic. Salary open, with early partnership. Write: Minnesota Medicine, 390, 375 Jackson, St. Paul.

WANTED: YOUNG PHYSICIAN for association leading to partnership with four well-established General Practitioners in fast-growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Contact: A. Eugene Muller, M.D., North St. Paul Medical Center, 2579 East 7th Avenue, North St. Paul, Minnesota 55109.

Law and Medicine

Complicating Developments in the Law of Criminal Responsibility

BARLOW SMITH, LL.B., M.D.*
Minneapolis, Minnesota

In recent decades the law of criminal responsibility in the United States has greatly modified the McNaghten test laid down more than a century ago** in England. Liberalization of that test has also brought some complicating developments.

New Hampshire in 1869 became the first American Jurisdiction to depart from the McNaghten rule.†

Irresistible Impulse Introduced Into the Federal Courts

In 1897 *Davis v. United States*# utilized the inability to distinguish between right and wrong together with what amounted to an irresistible impulse rule.

Matheson v. United States‡ in 1913 foreshadowed future developments in the charge to the jury to acquit if the crime "was the direct result or offspring of insanity."

The A.L.I. Rule

In 1953 the American Law Institute began a study which culminated in the drafting of a model Penal Code.

§4.01 provides:

(1) a person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or effect he lacks substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirement of law.

(2) . . . mental disease defects do not include an abnormality manifested only by repeated criminal or otherwise antisocial conduct.

§4.08(1) provides for mandatory commitment upon acquittal under these rules.

The Durham Rule

Finally in 1954 the District of Columbia substantially reiterated New Hampshire law in *Durham v. United States*§: a defendant may be considered innocent of a crime by reason of insanity if it can be demonstrated that the defendant was suffering from a mental defect at the time of the commission of the crime and, if so, whether the crime was a product of such mental disease or mental defect.

The *Durham* test for the first time gave psychiatrists the opportunity to characterize a defendant's psychology in unitary terms rather than within the narrow scope of distinguishing between right and wrong.

*New York Bar, the District of Columbia Bar and the Minnesota Bar.

§Durham v. United States, 214 F.2d 862 (1954).

Mandatory Commitment in The District of Columbia

Thereafter Congress enacted D.C. Code §24-301(d), providing mandatory confinement in a mental hospital for anyone acquitted by reason of insanity. The stated sincere purpose of the act was to safeguard the public. It was admitted in subsequent senate hearings on the subject that there was a widespread fear that the defense of insanity would be resorted to unscrupulously by criminals who would then go scot-free.*

As a matter of fact, hearings before the senate subcommittee on constitutional rights of the mentally ill in 1961 disclosed that the number of acquittals on the ground of insanity did indeed increase,** aided by the rule of the Federal District Courts that the government must prove sanity beyond a reasonable doubt where the defendant introduces only "some evidence" of insanity.†

Release of the Committed Defendant

Section 24.301(d) provides for release of a committed defendant who has wholly recovered and is no longer dangerous to himself or others. The *Ragsdale* case# in 1960 imposed upon defendant the obligation to show by the preponderance of evidence that he was free from an abnormal mental condition and stated that any reasonable doubt was to be resolved against the defendant. It was held in *Overholser v. Russell* in 1960 that the "danger to himself or others" of the D.C. Code need not be physical or a crime of violence, but "any criminal act."‡

Prosecution Introducing Evidence of Defendant's Insanity

Inevitably defendants began to avoid the defense of insanity in the District of Columbia. At the same time the prosecution began to introduce evidence of insanity on its own initiative. An example of this was *United States v. Kloman*,§ in which the defendant pleaded not guilty to assault of a policeman. Defendant was committed under Section 24.301(a) of the D.C. Code for pretrial mental examination to determine competency. Eventually he was returned to court as competent to stand trial. At the trial the prosecution argued that defendant was not guilty by reason of insanity. (Defendant claimed justification as a defense.) He was committed following a verdict of not guilty by reason of insanity.

Reluctant Acquittal

The question of reluctant acquittal was considered in *O'Beirne v. Overholser*:£ There defendant had been acquitted of petty larceny as insane. He was thereupon committed and remained so for 3½ years longer than the maximum sentence for petty larceny. At the same time he brought habeas corpus. His diagnosis had been sociopathic personality disturbance. At the time of his commitment to St. Elizabeth's Hospital the official position of that institution was that sociopathy was not a mental disease. While he was an inmate the official position changed to record sociopathy as a mental disease. Therefore the certificate of the superintendent that defendant was wholly recovered and not dangerous was denied on the ground that the patient was a sociopath. On appeal the denial of the certificate was held arbitrary and capricious because of the change of classification of defendant's mental condition, which was not considered a disease at the time of his trial and acquittal.

The Supreme Court Curtails Reluctant Acquittal

In *Lynch v. Overholser*¶ defendant had been acquitted of check forgery on grounds of insanity. His offer to plead guilty was rejected by the trial judge, who entered a not-

¶Lynch v. Overholser, 369 U.S. 705, 82 S. Ct. 1063, 8 L.E.2d 211 (1961).

guilty plea because defendant had been committed for pretrial examination to determine his competency. He had been found competent to stand trial, but it was considered "advisable to have further treatment" because he might "have relapses in the future." On the basis of the hospital report the Court refused the guilty plea. Thereupon and over his strenuous objection defendant was acquitted and committed. On appeal the Supreme Court avoided the constitutional questions. The Court held that the action of the trial judge was in error because the purpose of the statute was to protect against abuse of the *Durham* test whereby defendants might otherwise have gone free on easily obtained insanity acquittals. Public protection from dangerous individuals was held not to be a statutory purpose. These could be civilly committed. The Court ordered the defendant released unless civil commitment was commenced within ten days as provided by D.C. Code Section 21-310.

Lynch Decision Avoids Constitutional Issues

The Court did not consider the constitutionality of the commitment provision. Its statement of legislative purpose was at variance with the D.C. Court of Appeals in *Overholser v. Leach,** which stated that the primary purpose of the commitment provision was to protect the public from those who have committed criminal acts. The question was not whether the defendant was committed as innocent, because the verdict not guilty by reason of insanity most definitely was not an affirmative finding of present insanity; the verdict had the effect of including the defendant in a special class requiring hospitalization and treatment: ". . . there exists some rational basis for believing that the defendant suffered from a mental disease or defect of which the criminal act is a product," *Ragsdale v. Overholser.* An issue with which the Supreme Court in *Lynch* nowhere adequately dealt is the disparity between a finding of the jury or court relative to the defendant's state of mind during the commission of a particular act and commitment to a mental hospital on an indefinite basis without a finding of present insanity, as the District of Columbia Circuit has intimated.** This appears to be an unconstitutional deprivation of liberty which could readily be remedied by the institution of civil commitment proceedings following acquittal on the grounds of insanity, as English law now provides.†

The Currens Test Enunciated in the Third Circuit

In *United States v. Currens*# Chief Judge Biggs enunciated for the Third Circuit a rule similar to the *Durham* test. The new rule requires acquittal if a disease of the mind is shown and "the disease had so weakened his capacity to conform his conduct to the requirement of the law which he is alleged to have violated that he lacks substantial capacity to conform his conduct to the requirements of that law."

The Chief Judge distinguished his rule from that of the *Davis* case alluded to above, in which the test of irresistible impulse referred to control over conduct in question rather than to the more general conception of loss of willpower.

Other Circuit Courts Re-formulate Rules of Criminal Competence

Since *Currens* other Circuit Courts of Appeals have re-formulated rules of criminal responsibility. The Tenth Circuit essentially adopted the A.L.I. rule but changed the word *appreciate* to *know* in (1) of that rule.‡ The Second Circuit adopted the A.L.I. rule.§ The Eighth Circuit attempts to reconcile the A.L.I.

and McNaghten tests.*

Trend Among the States to Alter the McNaghten Test

These decisions reflect a trend among the states to alter the McNaghten test either by statute** or by judicial decision.† As things stand, a defendant may on identical evidence be acquitted by reason of insanity in the Second, Third or Tenth Circuit but convicted elsewhere. When the District of Columbia alone had adopted the *Durham* rule, no conflict existed since this was essentially a matter of legislation local in nature. Inasmuch as a split of authority now exists among the Circuit Courts of Appeal, the Supreme Court may feel compelled to consider the question of criminal responsibility for all the federal courts.

Prerequisites for Anomalous Assertion of Insanity by the Prosecution

The bizarre development in the District of Columbia, assertion of insanity by the prosecution, required more than a liberalized rule of criminal competence. Two additional predisposing conditions were: mandatory commitment upon acquittal by reason of insanity and a rule that sanity must be proved once evidence of defendant's insanity is introduced.

In Nebraska# as in the District of Columbia introduction of evidence of insanity shakes the presumption of defendant's sanity. Commitment upon acquittal by reason of insanity is mandatory too. But Nebraska follows the

*Duskey v. United States, 295 F. 2d 743, 759 (C.A. 8, 1961), cert. den., 368 U.S. 992, 82 S.Ct. 625, 7 L.Ed. 2d 536; Feguer v. United States, 302 F.2d 214, 245 (1962), cert. den., 371 U.S. 872, 83 S.Ct. 123, 9L.Ed. 2d 110. The Court preferred to "build upon . . . McNaghten and . . . irresistible impulse," utilizing three elements: cognition, volition and defendant's capacity to control behavior.

**Illinois: Chapter 38 Illinois Revised Statutes, Division I. Criminal Code of 1961, Title II, Article 6 §6-2: A.L.I. rule.

Once evidence of defendant's insanity is introduced, the presumption of sanity no longer prevails; burden of proof of sanity then devolves upon the state. People v. LeMay, 35 Ill. 2d 208, 220 N.E. 2d 184 (1966).

Upon acquittal by reason of insanity the fact finder must find whether "defendant has recovered from his former condition of insanity." Title VI §§115-3, -4 as amended by Act approved August 11, 1965.

If not found to have recovered, the court must thereupon commit to a mental hospital for a period not to exceed 12 months; defendant then becomes in all respects subject to §§8-12 of the Mental Health Code for civil commitment of the mentally ill, including discharge at the discretion of the head of the institution. Article 118, §118-2.

Maine: Maine Statutes ch 149 §38-2, added by Laws 1961, ch 310: Durham test.

Maryland: Md. Ann. Code, Art. 59, §9(a): A.L.I. rule. If in the court's discretion defendant should be confined following acquittal by reasons of insanity, the proceeding is as for civil commitment, Md. Ann. Code, Art. 59, §11.

Missouri: Mo. Stat. Ann. (1963), C.552, §552.030, sub§1.: A.L.I. rule in substance. Sub§5.: there is a conclusive presumption of criminal responsibility unless substantial evidence to the contrary is presented; burden of proof by a preponderance of evidence is upon defendant.

Montana: Laws of Montana (1967), C. 196, §95-501: A.L.I. rule. §95-508(2): defendant must be committed upon acquittal by reason of criminal non-responsibility, an affirmative defense for defendant to establish by a preponderance of evidence, §95-503(2).

New York: July 1, 1965: §1120 N.Y. Penal Law c. 40: "A person is not criminally responsible if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity to know or appreciate either

(a) the nature and consequence of such conduct

(b) that such conduct was wrong."

This effects no substantial departure from the McNaghten test.

Vermont: Vermont Stat. Ann., Title 13, §4801: A.L.I. rule. Commitment upon acquittal as non-responsible is discretionary with the court, §4805.

Virgin Islands: Title 14, Virgin Islands Code, §14(4): all persons are "capable" of crimes except

(1) children under the age of seven years;

(2) children over the age of seven years and under the age of fourteen years, in the absence of clear proof that at the time of committing the act charged against them they knew its wrongfulness;

(3) idiots;

(4) persons who are mentally ill and who committed the act charged against them in consequence of such mental illness; and

(5) persons who committed the act or made the omission charged under an ignorance or mistake of fact, which disproves any criminal intent.

The above changes were suggested by Third Circuit Court of Appeals Chief Judge Biggs, who wrote the opinion in Currens, supra.

†Connecticut: State v. Davis, 146 Conn. 137 (1959). To be the subject of punishment an individual must have the "mind and capacity, reason and understanding enough to enable him to judge of the nature, character and consequence of the act charged against him, that the act is wrong and criminal, and that the commission of it will justly and properly expose him to penalty."

Kentucky: Terry v. Commonwealth, 371 S.W.2d 862, 864-5 (1963): A.L.I. rule adopted in substance. After acquittal by reason of insanity the court may impanel a jury to decide whether defendant is presently of unsound mind, in which case he is confined until restoration of sanity. Russell's Kentucky Practice, RCr 9.90(2).

Massachusetts: Commonwealth v. McHoul, 226 N.E.2d 556 (1967): A.L.I. rule adopted. The burden is on the Commonwealth to prove defendant mentally responsible for the crime, Commonwealth v. Johnson, 188 Mass. 382, 74 N.E. 939, Commonwealth v. Clark, 292 Mass. 409, 198 N.E. 641. Introduction of evidence of insanity shakes the presumption of sanity, Commonwealth v. Cox, 327 Mass. 609, 100 N.E.2d 14(1951). Commitment of defendant as mentally ill after acquittal by reason of insanity is discretionary with the trial judge. Ann. Laws Mass. C278, §13.

Wisconsin: State v. Shoffner, 31 Wis. 2d 412, 143 N.W. 2nd 458 (1966). Defendant may elect to be tried under the A.L.I. rules if he accepts the burden of proof. This rule was admittedly adopted "as an experiment." (Shifting the burden of proof was a concession to the dissenting judges.) Should the defendant not accept this burden, he would be strictly entitled only to a charge under the McNaghten rule.

District of Columbia: McDonald v. United States, 312 F.2d 847(1962). The District Court here amplified the definition of mental disorder under the Durham test to include any abnormal condition of the mind which substantially effects mental or emotional processes and substantially impairs control over behavior.

In its opinion the court compared the other existing rules of criminal competence as follows:

McNaghten: cognition only

Durham: no standards for jury with respect to causation; irresistible impulse rule applied in the United States district courts too narrow to apply except in situations amounting to an explosive fit.

Wion: wording of A.L.I. rule changed from "appreciate" to "know."

Currens: substantial capacity to conform only: that part of the rule deleted which concerned appreciation of wrongfulness.

#Forske v. State, 123 Neb. 161, 242 N.W. 404(1932).

McNaghten rule.

In Michigan* and Oklahoma** commitment upon acquittal by reason of insanity is mandatory, but defendant has the burden of introducing evidence sufficient to raise a reasonable doubt; some evidence is not sufficient.

In Georgia,† Minnesota,# Nevada‡ and Ohio§ commitment is mandatory upon acquittal by reason of insanity; but defendant must prove insanity as an affirmative defense.

New Hampshire, home of the *Durham* test prior to its promulgation in the District of Columbia, makes commitment upon acquittal by reason of insanity discretionary with the court rather than mandatory.£ So does Massachusetts, which follows the A.L.I. rule.

Wisconsin makes commitment mandatory following acquittal by reason of insanity¶ but offers defendant the opportunity to be tried under the A.L.I. test only on condition that he assume burden of proof of insanity.[1]

Illinois meets the three conditions of mandatory commitment upon acquittal by reason of insanity, burden of proof of sanity once evidence of defendant's insanity is introduced and a liberal test of criminal competence, the A.L.I. test.

Thus, of the states here considered only Illinois provides the framework for anomalous assertion of insanity by the prosecution.

No Federal Statute Provides for Commitment After Acquittal by Reason of Insanity

A quite contrary situation exists in the federal criminal courts other than the District of Columbia: there is no federal statute providing for commitment of a defendant acquitted by reason of insanity.[3]

Perhaps Congress will react to the spread of more liberal rules of criminal competence among the Circuit Courts of Appeal as it did to *Durham*: fearing a deluge of acquittals by reason of insanity, it provided for mandatory commitment.

At present in the Second, Third and Tenth circuits defendant is aided not only by more liberal rules of criminal competence but also by the universal rule of the federal courts that the government must prove sanity beyond a reasonable doubt once some evidence of defendant's insanity is presented.

Deluge of Acquittals Avoidable in More Than One Way

Mandatory commitment upon acquittal by reason of insanity is not the only means of averting a deluge of such acquittals. Wisconsin achieved this result by shifting the burden of proof of insanity onto defendant.

Anomalous Assertion of Insanity by the Prosecution Can Be Avoided in Several Ways

Anomalous assertion of insanity by the prosecution has been laid to rest by *Lynch* in the federal courts. In the state courts New Hampshire avoids this threat by making discretionary with the court commitment following acquittal by reason of insanity.

Texas[4] avoids the threat of anomalous assertion of insanity by the prosecution while it solves the constitutional problem intimated in *Ragsdale* and evaded in *Lynch*. It does this simply by separating criminal guilt and the need for commitment to protect the public or treat the defendant psychiatrically. In case the defense of insanity is raised, the jury is asked to find whether defendant was insane[5] at the time of the alleged offense and whether insane at the time of the trial. If found insane at the time of the offense but sane at the time of the trial, he is set free.

If found insane at the time of the offense and insane at the time of the trial, commitment is mandatory, but defendant is treated as any other non-criminal patient committed for an indefinite period.

[2]See note**, p. 320.

[3]Commitment as incompetent before trial is covered by 18 U.S.C.A. §§4 244, -5. Commitment as insane after conviction is covered by 18 U.S.C.A. §§4241.

24 U.S.C.A. §211 does not provide for commitment upon acquittal by reason of insanity. It is inapplicable because ". . . it pertains solely to persons found to be insane, a finding which . . . cannot be made under existing federal criminal procedure." Sauer v. United States, 241 F.2d 640 at 651-2, n. 32(C.A. 9, 1957), citing 17 Op. Atty. Gen. 211 (1881).

[4]Vernon's Texas Statutes Annotated Art. 46.02 Sec. 1, 2, 3.

[5]Regrettably, Texas' test of criminal competence, essentially NcNaghten, Ex parte Hodges, 166 Cr.R. 433, 314 S.W.2d 581 (1958), does not match the adroit modernity of its criminal procedure in this area.

Conclusion

Developments in the law of criminal competence in the United States, while producing more liberal tests, have also resulted in complications. Some jurisdictions have, nevertheless, demonstrated that it is possible to provide more liberal tests of criminal competence while safeguarding against abuse and constitutional infirmity.

The Aftereffects

One day a patient with a long since healed leg fraction came to a Leningrad hospital. His leg was seven inches shorter than normal. A bony growth projected from the bone at the point of the fracture. The patient walked with crutches. Two improperly knit and shortened halves remained instead of the hip-bone. A part of the bone, reduced to fragments, had been extracted during the bone-setting operation.

The knit parts of the bone had to be disjoined and a bone plate taken from some other limb inserted between them. But a seven-inch-long bone plate was not all. The hip had to be strong enough to bear the weight of its owner, and a transplanted bone fragment could scarcely be expected to have such strength.

So the doctors decided to lengthen the leg to its natural length without implanting a bone fragment. Professor Bogoraz, a prominent Soviet surgeon, had proposed a most original method, and they were going to try it on their patient. It was an operation known as segmental osteotomy.

The improperly knit shortened bone is cut into oblique segments—two in the case of the top section of the broken bone, and two in the case of the other. If one of the sections is longer than the other, it may be cut into three segments. The doctors then use a special device to draw out the leg gradually to its normal length. The segments of the bone are pulled apart by the muscles, their oblique surfaces gliding one along the other. The upper end of one segment forms a continuation of the other's bottom end, forming a continuous chain of bone segments. A bony growth forms at their points of contact, joining them together for good.

An operation of this kind was performed on the patient, and a month later he was discharged from the hospital. His gait was firm. He left his crutches behind in the clinic.*

The Imaginary Line

The point of demarcation between normality and abnormality is purely an imaginary line sketched for the sake of convenience. As a youngster I had to reckon with the fact that a herd tightly bunched could not properly graze. I had to realize that there could be leaders and stragglers widely separated. And I had to learn to distinguish between those cattle forming the outer fringes of a fanned-out herd, and those deliberate strays heading off toward the corn fields. It was strangely similar to the eternal problems confronting the psychiatrist.*

GENERAL PRACTITIONER WANTED: To associate with Physician-Surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building 3 years old; with five large treatment rooms; lab.; x-ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85 bed City Hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D., 920 South Cedar St., Owatonna, Minnesota, Phone 451-4630.

PUBLIC HEALTH PHYSICIANS—Positions available in local health departments for medical doctors with medical experience and training in public health. Salary range from $18,000 to $23,000. Contact Mr. Roy Manty, Chief, Division of Local Health Administration, Department of Public Health, 3500 North Logan, Lansing, Michigan 48914. An equal opportunity employer.

GENERAL PRACTITIONER wanted to join well established practitioner in city of 5-6,000 and serving a population area of 18-20,000. Approximately 75 miles west of Mpls.-St. Paul. Well-kept clinic building two blocks from the hospital. Fully accredited 80 bed hospital with a resident Pathologist, Radiological Service, LPN School, X-ray Technician School, and complete Physiotherapy Department. Short-term association on salary basis or long-term association with eventual partnership, will accept, consider and appreciate either terms. Please send short resume of your education and previous experience. For further information about this opportunity write: Gregory M. Olson, M.D., Litchfield, Minnesota 55355.

WANTED—YOUNG INTERNIST. Board certified or eligible, to join 8-man group consisting of 6 GP's, a general surgeon, and a radiologist; college town of 5500 only 30 miles from Twin Cities; salary negotiable with early partnership opportunity. Write or call collect: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisconsin, phone 425-5322.

WANTED: GENERAL PRACTITIONERS, anesthesiologist, Urologist, Obstetrician, Orthopedist, & Pediatrician needed in growing community of 15,000. Service area 25,000. Present 83 bed general hospital. New 100+ bed automated hospital to be completed within 2 years. City has excellent industry, school system, and recreational activities. 45 minutes from Madison or Milwaukee. Future unusually promising. For more information contact: Administrator, Watertown Memorial Hospital, Watertown, Wis.

PHYSICIAN AVAILABLE: Active practitioner capable of doing most abdominal and Gyn. surgery, OB, fractures, X-ray. Wants to relocate close to or in Minneapolis. Write: MINNESOTA MEDICINE—391, 375 Jackson, St. Paul 55101.

WANTED—YOUNG GP, to join 8-man group of 6 GP's, a general surgeon, and a radiologist; college town of 5500 only 30 miles from Twin Cities; salary negotiable with early partnership opportunity. Write or call collect: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisconsin. Phone 425-5322.

GENERAL PRACTITIONER OR INTERNIST needed in six man group in Northeastern Minnesota. 38 bed accredited hospital next door to modern clinic, rotating call schedule, over 4 wks. vacation per year, study and sick leave, group paid disability and retirement plans, and full partnership in 6 months. Starting guarantee $18,000 to $22,000 with increases to $26,000 to $28,000 over 4 years. Ideal opportunity for man desiring association with active group in small community offering good income plus ample time off. Contact Harold B. Leppink, M.D., Community Clinic, Two Harbors, Minnesota. Phone Area 218 834-2171.

GENERAL PRACTITIONER with 25 years experience and a well-established practice in a suburb of the city desires a General Practitioner with an association towards a partnership. Write: MINNESOTA MEDICINE-389, 375 Jackson, St. Paul 55101.

The Venous System in Ancient Egypt

In the Heart are the vessels to the whole of the body.

There are four vessels to the Nostrils, two of which convey mucus and two blood.

There are four vessels in the inside of either Temple.

There are four vessels which divide in the Head and spread out in the back thereof.

There are four vessels to the Ears, two to the Right side and two to the Left. Breath-of-Life goes in the Right Ear and Breath-of-Death into the Left.

There are six vessels that run to the Arms, three to the Right and three to the Left, and they lead right down to the Fingers.

There are six vessels that lead to the Feet, three to the Right and three to the Left. They reach down to the Soles of the Feet.

There are four vessels to the Liver which convey to it Moisture and Air.

There are four vessels to the Intestines and to the Spleen which likewise convey Moisture and Air. There are two vessels to the Bladder which convey the Urine.

There are four vessels which end in the Rectum. They give and bring forth in it Moisture and Air. Afterwards they turn towards the Rectum, each vessel to the Right and Left side right down to the Feet, mixing itself with the excrement.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

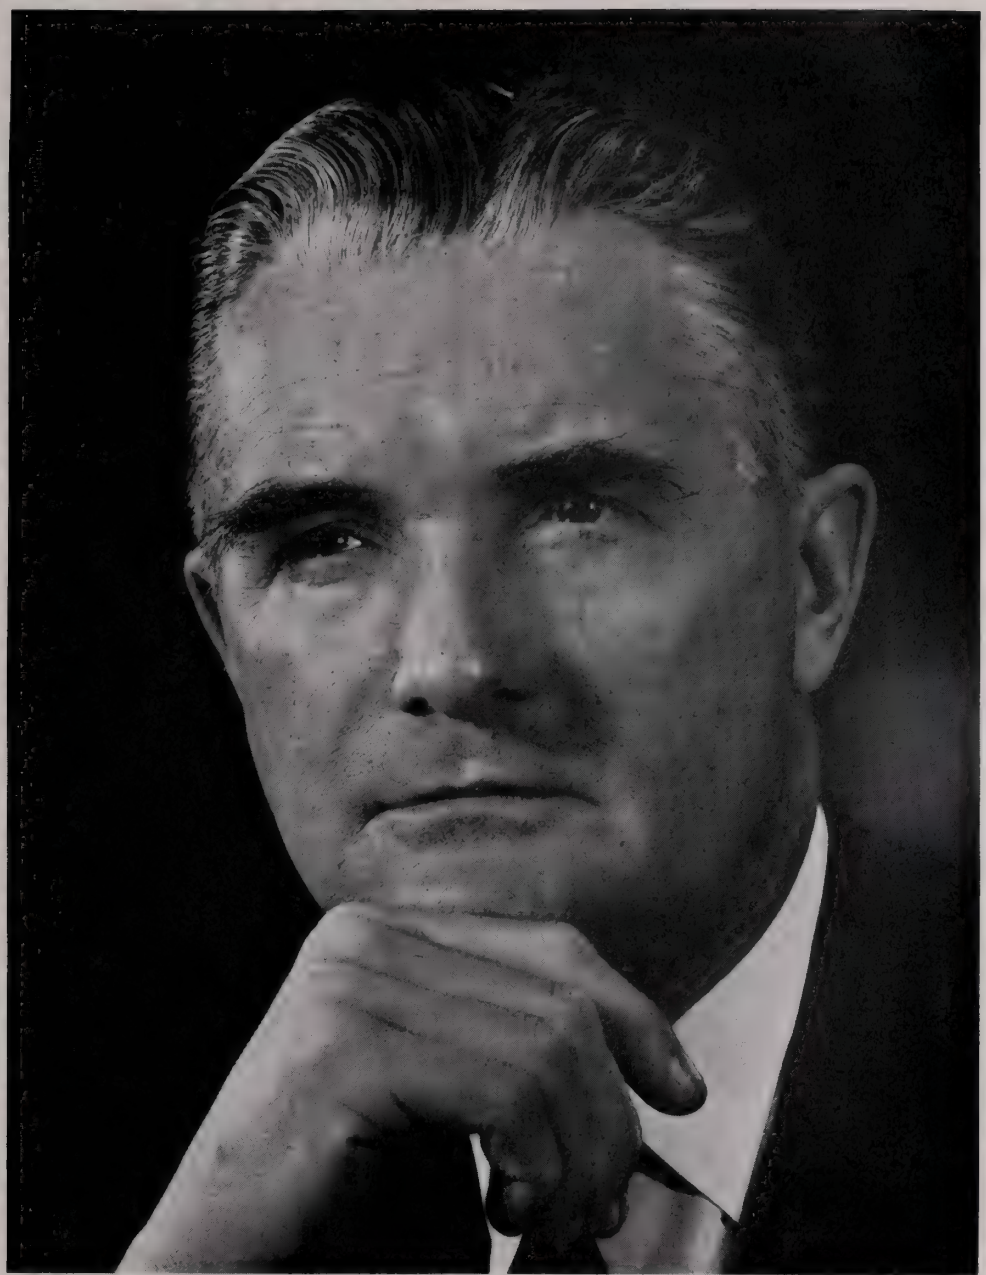
SAN FRAN CISCO AMA '68

The excitement of San Francisco's famous sites is waiting for you. Chinatown, the Golden Gate Bridge, Fisherman's Wharf, Telegraph Hill, will add to five memorable and stimulating convention days. Plan to attend now and look forward to an excellent convention in a city of unlimited charm.

Continue your postgraduate education with a varied program of • four General Scientific Meetings on Auto Accidents, Health Care Planning, Infectious Diseases, Treatment of Advanced Malignant Disease • 23 Section Programs • Color Television • Medical Motion Pictures • and over 600 scientific and industrial exhibits. All are designed to bring you up-to-date on what is making medical news today. You will attend lectures by the nation's outstanding medical authorities and discuss with them the significant advances in medicine.

In addition the AMA TV network will present more than 40 hours of convention news.



Reserve now for the Scientific Awards Dinner in honor of the Scientific Award Winners—Wednesday, June 19, 1968. Since space is limited, we suggest you make your reservations before June 3, 1968. Tickets are $10.00 each, payable in advance.

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, May 6, 1968.

President's Letter

How Many Surgeons Are Needed?

THERE HAS BEEN concern that our greatly expanded residency training programs are producing too many surgeons for the needs of our Minnesota communities.

Competition among surgeons can and should be beneficial to the ones utilizing their services: the referring physicians and their patients. When the surgeons are willing to subjugate the occasional unethical competitive urge, then the many advantages of a healthy competition become obvious.

Perhaps one of the earliest results of an abundance of personnel in a professional area is the effort of its members to become more highly trained. More years in a better training program permit of more attractive stature in the arena. The pursuit of excellence among surgeons must certainly bring obvious benefits to the recipients of their skill.

The creed of all physicians dictates a maximum effort and full devotion to the task of healing, and when competition serves to sharpen the intensity of the effort it is safe to say that this has been of value to the patient.

As their number increases, more of the newly well-trained surgeons find satisfaction, interesting activity and prosperous living in the smaller metropolitan communities. The general practitioner and internist in these cities no longer find it necessary to send their surgical patients away or to rely upon the part-time, partial services of the itinerant surgeon.

As the modern surgeon becomes more extensively trained he is perforce less well trained in other areas of medicine, and he therefore does not seek to build his specialty from a broad-based beginning in a general medical practice, but rather remains restricted to his own area of competence. This is one of the many benefits which accrue to the patient.

Abundance of general surgeons also has a tendency to gradually increase the ranks of the surgical sub-specialists and in turn to bring a greater supply of specialized talent and training to these areas.

As long as the competitive influence among the abundant supply of young surgeons promotes professional excellence and high competence, the health and welfare of the patient will be served. An over-supply of good surgeons is not foreseeable—except possibly in the distant future.

J. H. Strickler, M.D., President
Minnesota Surgical Society

The butterfly is the Fact—gleaming, fluttering, settling for an instant with wings fully spread to the sun, then vanishing in the shades of the forest. Whether you believe in Free Will or Predestination all depends on the slanting glimpses you had of the colour of his wings.—*Winston Churchill—Amid These Storms*

Encephalopathy and Fatty Degeneration of the Viscera

Reye's Syndrome

ROBERT F. MACK, M.D.*
Duluth, Minnesota

NECROPSY FINDINGS of encephalopathy and fatty degeneration of the viscera (Reye's syndrome) in a three-year-old boy, who survived a month after onset of his illness, stimulated a search of the literature in order to learn of other physicians' experience with this syndrome and to attempt to answer some of the questions which had been raised in our minds by the circumstances surrounding this case.

A review of the literature disclosed that the syndrome in children characterized by encephalopathy and fatty degeneration of heart, liver, and kidneys had first been reported in 1929 from England, in a study of six cases: five patients alive and one dead at the time of the report.[1] Thirty-four years later, in 1963, six reports of this syndrome appeared in the world literature containing a total of 68 cases: seven patients alive at the time of the reports and 61 dead.[2-7] The reports of Reye, Morgan and Baral[2] and Anderson[3] from Australia in that year had awakened an interest in physicians in England, Scotland, South Africa and New Zealand who had seen similar instances in their practices. In 1964, six additional fatal cases were added from Czechoslovakia.[8] In 1965, the United States literature reported the first seven cases from this country, all terminating fatally.[9-12] Three reports in 1966 from Czechoslovakia,[13] New Zealand,[14] and Scotland[15] added a total of 35 new cases, all with fatal terminations. The most recent report of five additional cases, one fatal, was from the Massachusetts General Hospital in 1967.[16] These 16 reports since 1929 have recorded 127 cases, with 16 patients alive and 111 dead at the time the authors wrote their papers.

Clinical Features

Age Incidence

The patients' ages have ranged from four months to 13 years, with the majority of

*Resident in Pathology, St. Mary's Hospital, Duluth, Minnesota.

cases occurring at about two years of age.

Initial Symptoms

The clinical features of the syndrome, described by Reye and his colleagues,[2] have not changed. The initial period of the illness includes malaise, cough, sore throat, earache, or rhinorrhea, in varying combinations. Usually one week after onset, but occasionally two to three weeks later, abrupt and severe vomiting occurs, followed by a semi-comatose state, and occasionally convulsions.

Physical Findings

Most patients have an abnormality of respiratory rate or rhythm. About half have a palpable, large, or firm liver. Muscle tone and tendon reflexes tend to be changeable; about ¾ of the patients had increased or variable muscle tone and tendon reflexes, about ½ had abnormal or equivocal plantar reflexes, and about one third had a characteristic posture with flexed elbows, extended legs, and clenched hands.

Laboratory Data

Clinical laboratory abnormalities are often encountered in the blood sugar, cerebrospinal fluid sugar, blood urea nitrogen, serum glutamic-oxalacetic acid transaminase (SGOT), and the differential white blood cell count.[2] The blood sugar is usually low. In Reye's group there were seven low blood sugar values; six patients had less than 50 mg.%, one patient had less than 62 mg.%, one had two reports of normal values and one had a hypoglycemia of 195 mg.%. Other investigators have confirmed this hypoglycemic tendency.[5,14,15] One group[5] emphasized that the hypoglycemia was not affected by glucose infusion.

The cerebrospinal fluid sugar was reduced to less than 25 mg.% in 13 of 19 patients.[2]

Blood urea nitrogen exceeded 40 mg.% in 75 per cent of the cases,[2,15] but marked elevations, above 50 mg.%, were unusual.[2,3,14] The serum glutamic-oxalacetic acid transaminase was estimated in only seven cases, all of which showed elevations ranging from 106 to 1170 Karmen units per ml. per minute.[2]

Bacterial and viral studies, when performed, were usually negative.

In Simpson's study,[15] the most common acid-base disturbance was metabolic acidosis, often associated with respiratory alkalosis due to hyperventilation. Simpson reported six patients with a pH range from 6.85 to 7.47.

Electroencephalographic Findings

Reye, Morgan and Baral[2] reported electroencephalographic abnormalities in this syndrome. All the patients studied had gross and generalized changes.

Etiology

Viral and toxic etiologies have been postulated without proof. Becroft,[14] in a detailed speculation, also postulated that nutritional, endocrine, and genetic factors might be important. He concluded, as others had, that the etiology is unknown.

Treatment

Symptomatic therapy, with attempts to correct inadequacies of ventilation and to combat hypoglycemia and acid-base alteration, has been employed.

Pathologic Findings

Gross

In all instances the findings at necropsy have been similar. Grossly the brain is edematous and swollen with flattening of the cerebral convolutions. The liver is slightly enlarged, firm, and yellow. The kidneys and myocardium have a slightly yellowish hue.

Microscopic

Microscopically the brain tissue changes are nonspecific and neuronal. The neuronal cells may be swollen or shrunken and deep-staining. The cerebral capillaries and small vessels have fat-filled endothelial cells. Inflammatory changes are absent.

Fat-filled parenchymal cells are found in a diffuse, uniform distribution in the liver, in the muscle fiber of the heart, and in the proximal convoluted tubules and proximal loops of Henle of the kidneys.

Report of a Case

Presenting Complaint

An apparently healthy 35-month-old white boy was

admitted to St. Mary's Hospital in Duluth on December 6, 1965, with a history of having been well until one day before admission. He had vomited five or six times during the day. About three hours prior to admission, he had had trouble clearing his throat, which his father thought was "dry heaves." Then the boy had become flaccid and unresponsive and was brought to the hospital.

Past History

The child had had no previous surgery, trauma, or serious illnesses, and careful questioning elicited no history of allergy or drug ingestion. No other member of the family was ill.

Initial Physical Findings

The boy was comatose on admission, his temperature was 98.6° (F.) and his breathing was labored. He appeared well developed and well nourished and his skin was clear. The pupils were equal, regular, and reacted to light and accommodation. The nose was patent. The lungs, after aspiration of the tracheobronchial tree, were clear. The heart was normal; no enlargement or murmur was found. The abdomen was soft; neither liver nor spleen was palpable. Neurologic examination disclosed an absent gag reflex, symmetrical tendon reflexes, with a questionably positive right Babinski. He responded to painful stimuli and exhibited no posture characteristic of a known disease.

Laboratory

Laboratory values on admission disclosed a hemoglobin level of 13 Gm., a white blood cell count of 58,000 with 15% nonsegmented neutrophils, 57% segmented neutrophils, 23% lymphocytes, and 5% monocytes. The blood urea nitrogen was 28 mg.%, the serum sodium 139 mEq /L, the serum potassium 5.4 mEq/L, the serum chlorides 102 mEq/L, and the serum carbon dioxide content 27.1 mEq/L. The urine had a specific gravity of 1.017, was negative for sugar and acetone, showed a trace of albumin and 0-1 white blood cells, and a rare red blood cell per high-powered field. A blood culture, drawn on admission, was reported negative after 14 days' incubation. Cerebrospinal fluid was under normal pressure; cultures and smears of the fluid were reported negative for pathogens. The spinal fluid protein level was 19 mg. %; no cells were found.

Progress Report

Six hours after admission, respiratory embarrassment necessitated a tracheostomy. A chest x-ray the first day, after tracheostomy, showed changes compatible with bilateral bronchopneumonia. Examination at that time showed the patient to be in a semistuporous state with bilateral positive Babinski signs.

During the three days following admission the patient's state of consciousness gradually improved. A brain scan with 125 microcuries of Hg^{203} showed an essentially normal pattern two days after admission. On the third hospital day, an electroencephalogram (without prior sedation) was considered "probably normal." Blood sugar was 72 mg.%. Parenteral fluid therapy during the first four days included glucose and electrolyte replacements. The tracheostomy tube was removed on the fifth day after admission.

Over the next 28 days the patient gradually improved except for persistence of an ataxic gait. However, his hand coordination was not affected, for he could put together a jig-saw puzzle.

Because of the long period of disability, the presence of ataxia, and the possibility of a brain tumor existing, pneumoencephalography was performed on the 33rd hospital day. Preoperative atropine (1/300th grains) was given 80 minutes prior to induction. The procedure, done under sodium pentothal anesthesia (700 mgm. rectally before anesthesia and 400 mgm. intravenously) without difficulty, showed that no air was delivered to the ventricular system. The subarachnoid space was well visualized and showed increased depth and width of the sulci, suggesting a moderate degree of atrophy.

Following the pneumoencephalography, the patient was sent to the Intensive Care Unit for post-anesthetic observation. Continuous drowsiness persisted and, 23 hours after the procedure, acute deterioration was obvious. Examination showed a lethargic patient with a respiratory rate of 60/minute and a heart rate of 160/minute. Respirations became Cheyne-Stokes in type and the heart tones became inaudible. There was no response to resuscitative measures and the patient died 24 hours following the pneumoencephalogram.

Necropsy Findings

Gross

Necropsy was performed four hours after death. No remarkable, grossly detectable discoloration was seen in the heart. The liver weighed 680 grams and was diffusely yellow. The kidneys appeared normal. The brain

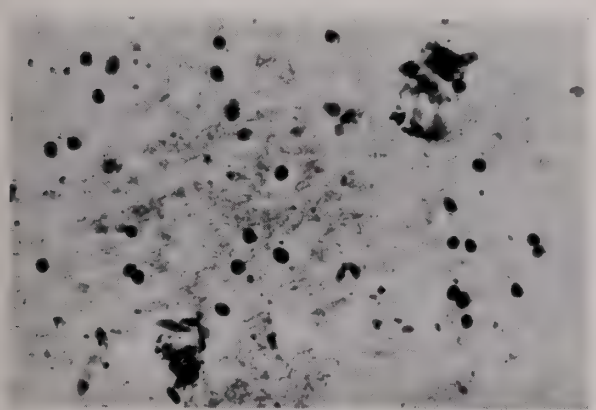

Fig. 1—Oil red 0 stain showing fat in endothelial cell of brain vessels.

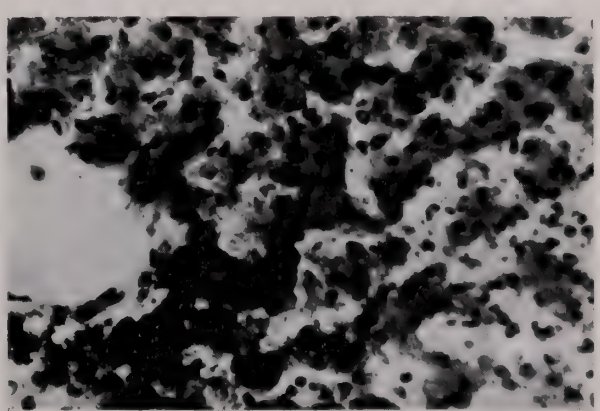

Fig. 2—Oil red 0 stain showing fat in liver cells.

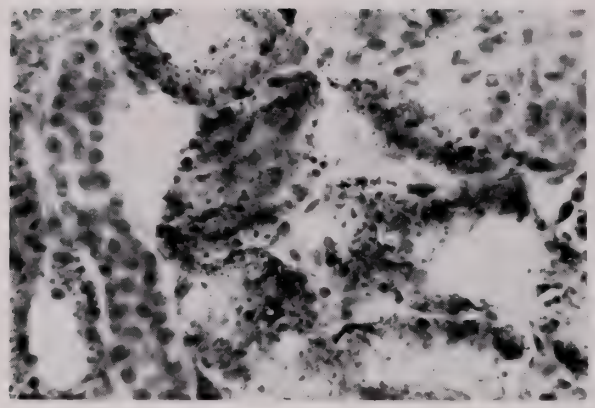

Fig. 3—Oil red 0 stain showing fat in proximal tubules of the kidney.

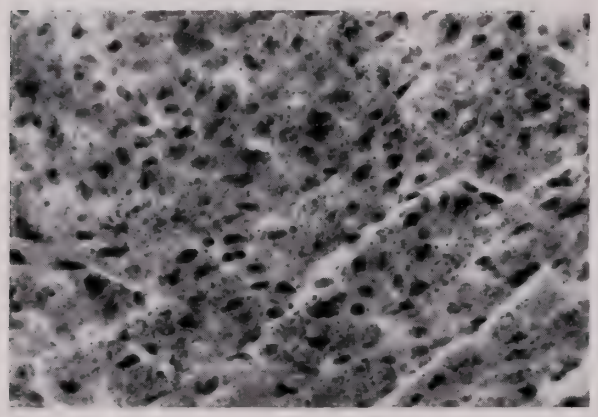

Fig. 4—Oil red 0 stain showing diffuse particulate fat in the myocardium.

weighed 1330 grams and showed narrowed sulci and broad, flattened gyri in close approximation. A coning defect was present in the cerebellar tonsils. (This undoubtedly resulted from increased intracranial pressure, and the resultant herniation was the cause of death.) Transection of the cerebral hemispheres disclosed no tumor, hemorrhages, or infarction. There were no other pertinent, significant gross findings.

Microscopic

Histologic examination showed petechial pontine hemorrhages; fat-stains of the brain revealed capillary endothelial cells containing fat (Figure 1). A few neurons were swollen, while others were contracted and showed an increase in basophilic staining. Special stains of the liver also showed diffuse fatty change (Figure 2). The proximal tubules of the kidney showed similar fatty change (Figure 3). Finely dispersed, fatty fiber infiltration was found in the heart (Figure 4). A specimen of blood, drawn at postmortem examination, was negative when cultured.

Comment

Although the laboratory and autopsy findings in this patient are similar to those reported in the literature, his course differed from the course of the usual victim of this syndrome in the unusually long duration of illness and in the finding of the fatty degeneration 33 days after the onset. One patient, who was reported to have survived this syndrome, had a specimen of liver taken for biopsy three weeks after the acute episode, and this tissue was histologically normal.[2] This case seems to be the first with fatty degeneration and encephalopathy that retained the histologic fatty feature for an extended period of time.

Another feature worthy of serious consideration is illustrated by the patient's rapid decline after sodium pentothal anesthesia. Sedation with barbiturates may be dangerous in patients with encephalopathy and fatty degeneration.

Summary

The clinical, biochemical, and pathologic changes of the syndrome of encephalopathy and fatty degeneration of the viscera (Reye's syndrome) are reviewed with two new observations: one, persistence of fatty degenerative changes for over a month after the onset, and second, rapid deterioration and death after barbiturate anesthesia.

A CALCULUS in the ureter threatens the functional and anatomic integrity of the kidney and at times the life of the patient. In most instances, the calculus must be removed by spontaneous passage, cystoscopic manipulation, or ureterolithotomy.†

There are a number of factors to be considered in determining the course of management (Table 1). The size and location of the calculus within the ureter are perhaps the most important; however, there are other prerequisites that also influence the decision. Calculi, 0.5 cm. in greatest diameter or smaller, demonstrating progressive movement down the ureter, causing little or no pain and without significant obstruction or infection, might reasonably be expected to pass spontaneously. The decision to await spontaneous passage is a difficult one. Close observation is mandatory in the event of emergency, and facilities should be available for immediate cystoscopic manipulation or ureterolithotomy. The patient who has chronic renal disease or a solitary kidney and harbors a ureteral calculus may be in extreme danger, and to await spontaneous passage may be life-threatening.

The prerequisites for selection of conservative management are also applicable in determining the need for definitive surgical treatment. Once it is determined that the calculus is incapable of spontaneous passage, the alternatives must be carefully considered.

To choose ureterolithotomy or cystoscopic manipulation of a ureteral calculus is not a question of which method is technically easier to perform, but which is in the best interest of the particular patient under consideration.

With this in mind we have reviewed a successive group of patients with ureteral calculi, in whom the treatment was either ureterolithotomy or cystoscopic manipulation, in an

effort to more clearly define the guidelines that influence the decision regarding definitive management.

Our Series

Ninety-five consecutive patients with a diagnosis of ureteral calculus underwent definitive surgical treatment, either cystoscopic manipulation or ureterolithotomy, or ureterolithotomy combined with other upper urinary-tract surgery. In this last group with combined procedures, there were 14 patients, including six with combined pelviolithotomy and ureterolithotomy, six whose stone disease required nephrectomy with either partial or subtotal ureterectomy, and one patient with bilateral ureterosigmoidostomies, in whom the ureteral calculus was detected at the time of urinary diversion. In one patient the calculus was found in the stump of a ureter. These 14 cases were not considered suitable for evaluation.

Findings

Ureterolithotomy or cystoscopic manipulation of the ureteral calculus was the primary treatment in the 81 patients. Patients' ages ranged from 11 to 78 years, and males predominated in a ratio of 4 to 1. The peak incidence was in the fourth and fifth decades. The calculus displayed no preference for the right or left ureter.

The presenting signs and symptoms for the entire group of patients with ureteral calculi are seen in Table 2. The majority of patients presented with some form of pain, principally that of renal colic. Four patients were asymptomatic, and these required ureterolithotomy because of associated chronic renal disease significantly aggravated by the presence of a calculus.

Ureterolithotomy was the selected form of management in 36 of the 81 patients. Thirty-nine calculi were removed; three patients had two calculi each. The relationship of calculus size to location in the ureter is shown in Table 3. Thirty-seven of the 39 calculi were 0.5 cm. in diameter or larger; only nine of these 37 calculi were less than 1.0 cm. Only six calculi situated in the lower third of the ureter required ureterolithotomy; five of these were at least 1.0 cm. in diameter. Thirty-three of the

39 calculi removed by ureterolithotomy were in the upper and middle thirds of the ureter.

Postoperative complications developed in 15 of the 36 patients (Table 4). The most frequent complication was prolonged urinary drainage through the drain site (10 of 15 patients). There was no relationship between method of closure of the ureterotomy incision and prolonged drainage.

Forty-five patients with ureteral calculi were deemed suitable for cystoscopic manipulation (Table 5). One calculus, 0.7 cm. in greatest diameter, was successfully extracted from the middle third of the ureter. The remaining 44 calculi were located in the lower third. Manipulation was attempted on only one calculus larger than 2.0 cm. in diameter, and this was unsuccessful. The majority of calculi in this group were less than 1.0 cm., although seven of nine calculi 1.0 cm. or larger were successfully extracted. Attempted cystoscopic manipulation of a ureteral calculus was successful in 38 of 45 patients, a success rate of 84%.

Complications after successful cystoscopic manipulation of 38 calculi included two patients with renal colic secondary to blood clot, one patient with transient bacteremia, and one with acute pyelonephritis.

Attempted cystoscopic manipulation was unsuccessful in seven of 45 patients. Subsequent ureterolithotomy was carried out 48 to 72 hours after attempted manipulation on four patients (Table 6). The one patient with ureteral perforation, which occurred secondary to manipulation, was managed by immediate ureterolithotomy. The one whose ureteral calculus passed spontaneously 48 hours after attempted manipulation might reasonably be considered a successful result of cystoscopic manipulation; however, since the calculus was not extracted at manipulation, it is not counted as such.

Discussion

There are advantages and disadvantages accompanying the selection of either method of calculus removal. However, there are useful guidelines which may serve to minimize the subsequent morbidity known to be associated with either technique. The enthusiastic use of one method to the exclusion of the other is to be condemned. An intelligent appraisal of the prerequisites for cystoscopic manipulation or ureterolithotomy is in the best interest of the

patient.

Successful cystoscopic manipulation of a ureteral calculus in 84% of the patients was accompanied by a minimal morbidity, whereas ureterolithotomy was associated with a significant morbidity rate. The difference is reflected in the average time of hospitalization for patients in each group (Table 7). When ureterolithotomy was performed, patients could be expected to remain in the hospital an average of five days longer than patients undergoing successful manipulation, if no complications resulted; or an additional 11 days with associated complications. Successful cystoscopic manipulation, even when accompanied by complications, increased the in-hospital time by only 2.6 days.

TABLE 7
Average Time of Hospitalization (Days)

Group	Without complications	With complications
Successful manipulation (38 patients)	6.4	9
Ureterolithotomy (36 patients)	11.4	17.8

Calculi that are located in the upper or middle third of the ureter and that fail to descend are usually larger than 0.5 cm. in diameter; and when associated with persistent subjective and objective findings, these calculi should be removed by ureterolithotomy. Similarly, calculi situated in the lower third of the ureter and greater than 1.0 cm. in diameter will probably require ureterolithotomy, although an initial attempt at cystoscopic manipulation should be considered, and at times such manipulation may be successful.

Cystoscopic manipulation should be considered for all calculi 1.0 cm. or less in greatest diameter, if located in the lower third of the ureter, since such calculi may be confidently extracted in most instances. Calculi larger than 1.5 cm. usually will not be suitable for manipulation. Patients known to have associated chronic renal disease, previous renal or ureteral surgery, or a solitary kidney are more likely to require ureterolithotomy. In this series, 29 of the 36 patients requiring ureterolithotomy gave a history of acquired and congenital abnormalities or of recurrent urinary-tract calculi. Of the 45 patients requiring cystoscopic manipulation of a ureteral calculus, only 11 revealed a significant history of renal disease. The results of cystoscopic intra-ureteral extraction of ureteral calculi compared favorably with other reported series.[1-3] Successful extraction of the calculus may be confidently expected in at least 80% of patients, provided the necessary prerequisites for attempting manipulation are satisfied. Similarly, postoperative morbidity can be expected to be significantly less with manipulation than with ureterolithotomy. In this series, successful cystoscopic manipulation was accompanied by a hospital stay of 6.4 days as compared with 11.4 days for patients with ureterolithotomy.

An inflexible attitude that favors either method of calculus removal seems unwarranted, because suitable guidelines do exist for the appropriate selection of either method.

Coronary Arteriography

Selective vs. Non-selective Methods

GERALD B. LEE, M.D.*
St. Paul, Minnesota

KURT AMPLATZ, M.D.**
Minneapolis, Minnesota

CORONARY ARTERIES were first visualized in man using contrast materials in 1945.[1] Since then various methods have been introduced to visualize the coronary vessels. Non-selective coronary arteriography has been generally unsatisfactory because of the inconsistency in coronary arterial filling despite prodigious† flooding of the root of the aorta with contrast material. A review of 1000 thoracic aortograms at the University of Minnesota Hospitals[2] using a single injection of contrast material through a large bore catheter showed wide variation in coronary artery filling. Various methods employed to reduce cardiac output temporarily or inject contrast material during diastole[3,4] not only have proved hazardous but have not produced adequate visualization of the coronary vessels[5,6,7,8,9,10] according to present-day standards.

In our experience the loop or ring catheter with multiple side holes positioned in the aortic root just above the aortic valve has proved the most satisfactory non-selective method of coronary arteriography. Recently we have studied twelve patients by non-selective and selective arteriography. The comparative value of the root aortogram utilizing a ring catheter vs. the selective coronary arteriogram form the basis of this report.

Materials and Methods

One hundred twenty-two patients had bilateral selective coronary arteriograms. Of these patients, 12 had an additional aortogram using a ring catheter. The method of selective catheterization — percutaneous transfemoral—has been reported previously.[2,11] Five of the twelve patients had an aortic root injection by means of a ring catheter since it was not possible to cannulate the right coro-

†See Test Your Word Score Page 375.

nary ostium. At a later date each of these five patients was studied by a selective right coronary arteriogram.

The right coronary artery and two major branches of the left coronary artery—the left anterior descending and the left circumflex branch—were graded separately. The selective and non-selective arteriograms were graded independently. Each vessel was graded on the basis of filling and opacification as follows:

Excellent filling,	4+	
Good filling,	3+	
Fair filling,	2+	
Poor filling,	1+	
No filling,	0	(zero)

Results

Root aortography in this group of patients produced only "fair" or "poor" visualization of the coronary arteries. However, there was "good" to "excellent" opacification of the right coronary artery in five patients (Table).

By selective angiography there was excellent filling of the coronary vessels in the majority of patients studied.

Case Report

A 46-year-old white married male complained of palpitations unrelated to exertion for four years. As a child he had had "pneumonia" but did not give a history of rheumatic fever. There was no history of angina pectoris, syncope, or congestive failure. Physical examination revealed a blood pressure of 130/78 mm. Hg.; the pulse was 80 and regular. The heart was not enlarged. There were a grade 2/6 systolic ejection murmur at the aortic area and a faint early blowing diastolic murmur at the lower left sternal border.

The routine blood and urine studies as well as the chest x-ray, electrocardiogram and vectorcardiogram were normal. The Master's test was negative. The aortic valve region appeared calcified at fluoroscopy.

Angiography

Right heart catheterization revealed all pressures in the right atrium, ventricle and pulmonary artery to be normal. The cardiac output (Fick method) was 3.64 L/min. at rest; with exercise the output rose to 5.30 L/min. The left ventricular pressure was 152/8. The end diastolic pressure did not change significantly during exercise. There was no evidence of mitral insufficiency during left ventricular angiography. There were a 28 mm. Hg. systolic gradient across the aortic valve and mild aortic insufficiency noted during thoracic aortography using a ring catheter with multiple side holes (Figure 1).

Interpretation

Mild poststenotic dilatation of the ascending aorta was noted. The right coronary artery, the left anterior descending branch of the left coronary artery and the left circumflex branch of the left coronary artery were partly visualized (Table, Patient No. 1). Several areas in the coronary arterial system were thought to be narrowed

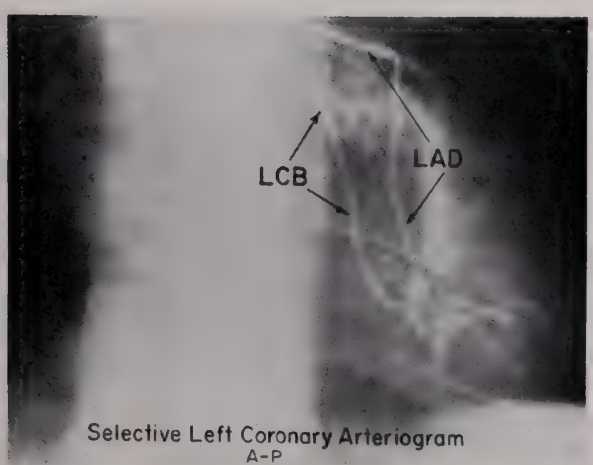
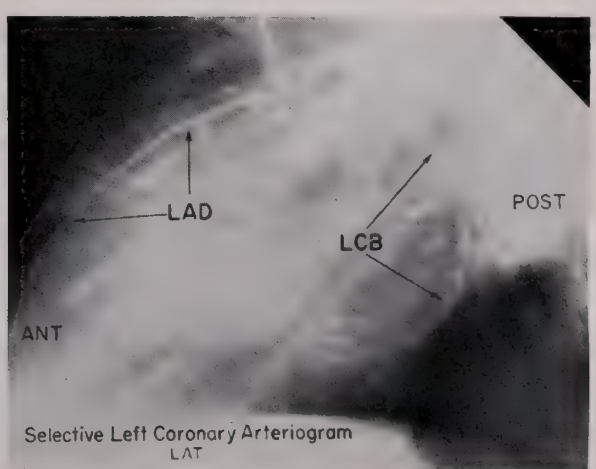
**** Coronary artery disease





Figures 1—Note that the coronary arteries are visualized but despite the use of the ring catheter and prolonged Valsalva, the anatomical detail is poor. The right coronary artery is seen more clearly than the left anterior descending and the left circumflex branches. Both the left anterior descending and the left circumflex branches appear to be diffusely narrowed using this technique.

Figures 2—There is excellent filling of the right coronary artery, left anterior descending branch and left circumflex branch. All large coronary vessels appear normal.

by atherosclerotic plaques. Because of this a selective coronary arteriogram was performed three days later showing completely normal coronary arteries (Figure 2).

Comment

In our hands bilateral selective coronary arteriography is possible in 95% of patients studied and is consistently superior to non-selective root aortography in defining coronary artery anatomy and pathology. It is not possible in many cases to adequately opacify all major coronary branches by aortography. In a study by Sones and Shirey adequate visualization of the coronary arteries was possible in less than 70% of the patients studied by aortography.[12]

The clinician and radiologist are frequently misled by the thoracic aortogram. What appears as segmental coronary narrowing by aortography is frequently found to be normal either by selective coronary arteriography or at necropsy. Conversely there may be more coronary lumen narrowing demonstrated by selective coronary arteriography or at necropsy[13] than was suspected from the aortic root study. We have seen at our institution three patients who were thought to have severe coronary narrowing on the basis of a root aortogram. However, at necropsy they were found to have only minimal coronary narrowing. We feel that the root aortogram is misleading in some cases because of inadequate filling of coronary vessels and in other cases because of "layering" of contrast material.

Selective coronary arteriography has been helpful in other situations where non-selective aortograms have been of little value. Coronary anastomoses have been demonstrated in 25% of the patients studied.[11] Coronary arteriovenous fistulae and anomalous origin of the left coronary artery from the pulmonary trunk have been documented. In addition, selective angiography has shown more clearly anomalous distribution of coronary vessels—an important finding for the cardiac surgeon.

Conclusions

The risk of selective and non-selective coronary arteriography at our institution is the same.[11] We prefer selective coronary arteriography since it is the most accurate diagnostic method available today. Despite all these arguments in favor of the selective method there are groups[14] that find the non-selective coronary arteriography the method of choice.

Disease

The diseases of the present have little in common with the diseases of the past save that we die of them.—Agnes Repplier

Nodules in the Substance of the Upper Lip

JOHN B. ERICH, M.D.*
FAWZI ABU JAMRA, M.D.**
Rochester, Minnesota

NOT ONLY ARE nodules in the substance of the upper lip infrequent, but many surgeons tend to regard these lesions as inconsequential. As a result, such nodules may be hastily and inadequately removed, sometimes without subsequent microscopic examination. We have found that most nodules in the substance of the upper lip represent tumors which, if not properly excised, will readily recur even though they are benign; furthermore, if malignant, these growths are sometimes difficult to control. Another observation worthy of mention is that the tumors discussed in this paper, although rare in the upper lip, are much less common in the lower lip.

The literature on this subject is meager. Chaudhry and co-workers[1] found that there were 43 cases of benign tumors of the minor salivary glands at Minneapolis and St. Paul hospitals from 1939 to 1960. Of these 43 tumors, 40 were mixed tumors; three were located in the upper lip and none in the lower lip. These authors also reviewed the literature from 1924 to 1960; they discovered that of 733 mixed tumors in the minor salivary glands, 105 were in the upper lip and 13 in the lower lip. In addition, they found six cases of cylindroma† (adenoid cystic carcinoma) of the upper lip. Fine and associates[2] reviewed tumors of the minor salivary glands in the mouth and pharynx treated at the Henry Ford Hospital from 1916 to 1959. Of 42 benign tumors, 25 were mixed tumors; five of them were located in the upper lip. Furthermore, two cases of cylindroma of the upper lip were described.

In our study of nodules in the substance of the upper lip, the records of all patients with benign and malignant lesions of the upper lip seen at the Mayo Clinic from 1944 to 1963 inclusive were abstracted. However, those tumors that started in adjacent tissues and in-

*Mayo Clinic and Mayo Foundation: Section of Plastic Surgery.

†See Test Your Word Score Page 375.

volved the upper lip by direct extension were excluded.

Surprisingly, only 36 patients with tumors located in the substance of the upper lip were encountered. However, the pathologic nature of these neoplasms was interesting (Table). It is evident that very few tumors in the substance of the upper lip are inconsequential. Mixed tumors, the most common benign growths will recur promptly unless adequately removed, and the malignant neoplasms all present serious problems.

TABLE
Distribution of 36 Patients With Upper-Lip Tumors

Type of tumor	No.	Per cent
Benign		
Mixed tumor	24	66.6
Mucous cyst	3	8.3
Inflammatory lesion	2	5.6

Metastatic carcinoma	1	2.8
Total	36	100.0

Benign Tumors

Mixed Tumors

Of the 24 patients with mixed tumor, 14 were males and 10 were females. The nodules in two patients were adherent to the skin, whereas in the remaining 22 the growths were located in the substance of the upper lip, unattached to the skin or mucosa. The average age of patients with mixed tumor was 52.5 years; 66.6% were between 30 and 59 years old. Although the duration of such a neoplasm often is difficult to determine, 75% of the patients had had their lesions from two to 15 years. In 21 patients in whom the size of the nodule was specified, the sizes ranged from 0.1 to 3 cm. Although such growths can be painful, usually they are symptomless, the patient complaining only of a lump or swelling in the lip. Two patients had a history of trauma which, no doubt, had nothing more to do with the tumor than call it to the patient's attention.

Usually a mixed tumor arises from the epithelial elements in salivary glands, but they may occasionally develop from similar cellular components in sweat glands. Such neoplasms generally are well encapsulated and they grow slowly. Microscopically, nests or strands of epithelial cells surrounded by a mucoid or chondroid stroma can be seen. Cartilage was present in three tumors.

In four of the 24 patients with mixed tumor, the tumor was recurrent; it had been excised prior to the patient's registration at the clinic. At our institution, treatment consisted of wide excision, with either primary closure of the wound or local plastic repair.

Analysis of the results of treatment revealed that only one patient was known to have a recurrence. This patient was observed but not treated at the Mayo Clinic. The patients were followed up for from two to 17 years; however, four patients were lost to follow-up.

The one patient who had a local recurrence was a 39-year-old woman. She had noticed a nodule in her upper lip. The nodule had been excised by her home physician prior to her first examination at the clinic, and the pathologist had reported that the growth was a cylindroma. This prompted her home surgeon to re-excise the involved region. Subsequently, the patient was seen at the Mayo Clinic where the slides of the previous excision were reviewed, and a diagnosis of benign mixed tumor was made but no treatment given. Five months later another tiny nodule appeared in the upper lip. However, the surgeon in the patient's home community elected not to remove it, and no further information was available.

Mucous Cyst and Inflammatory Tumors

Five patients had a lump in the substance of the lip. In three, the lump was near the mucosa, and the diagnosis was indeterminate clinically. On excision, however, the three submucosal nodules proved to be mucous cysts, and the other two lesions were found to be inflammatory.

Malignant Tumors

Cylindroma (Adenoid Cystic Carcinoma)

Four patients in our series, three women and one man, had a cylindroma in the upper lip. The ages of these patients ranged from 34 to 60 years, with an average of 48.2 years. The sizes of the lesions varied from 1 to 3 cm. When the four patients sought treatment at the Mayo Clinic, the lesions had been present 10

years, five years, six years, and five months, with an average of 5.7 years. The signs and symptoms were no different from those of patients with mixed tumor; the chief complaints were a lump or swelling and occasionally soreness or discomfort.

Microscopically, cylindromas have a honeycomb or Swiss-cheese type of cellular pattern. The cells are small and uniform in size, have dark nuclei, and are arranged in layers around cyst-like spaces that may contain mucus or hyaline material. Being poorly encapsulated, the tumors may show evidence of infiltration into the surrounding tissues.

All four patients had had some form of surgical intervention prior to examination at the clinic. In two patients, the lesion was explored and biopsied; in the remaining two, the growth was excised, one of them on two occasions. At this institution, two patients had their primary lesion treated by excision and electrocoagulation, one patient had electrocoagulation alone, and the fourth had interstitial irradiation in the form of radon seeds for a lesion that had recurred a second time.

Studies concerning the results of treatment revealed that two patients had metastatic lesions; one of these patients also had evidence of local recurrence.

In our experience, a cylindroma in any location is almost certain to recur in spite of having been widely removed. Although its growth is especially slow, this tumor is extremely serious; local recurrences and metastases, both regional and distant, are common, the lesions making their appearance anywhere from one to 10 years or more after the initial treatment. Pulmonary metastasis from cylindromas is a frequent complication of this disease and can be present for years without causing noticeable symptoms. We were surprised to find that two of the four patients with cylindroma of the upper lip were living 16 and 18 years after treatment of the primary tumor, with no apparent evidence of local recurrence or metastasis.

In one of the two patients with metastasis, both lung fields were involved, but there was no sign of recurrence of the primary lesion. The pulmonary lesions became evident 5 1/4 years after the initial treatment of the cylindroma in the lip. Unfortunately, this patient was lost to further study. In the other patient, the primary tumor recurred and metastatic lesions developed in regional lymph nodes below the body of the mandible five years after treatment of the primary tumor. The metastatic nodes were treated by interstitial radiation. Two months later, a metastatic lesion appeared in the left lung, and after an additional 15 months, the pulmonary metastatic nodule had grown eight times larger. This patient was a 34-year-old man who was still living seven years after the initial treatment.

Other Malignant Nodules in the Substance of the Upper Lip

The remaining three malignant nodules occurring in the substance of the upper lip in our series involved one leukemic infiltrate that occurred in a four-year-old boy with acute leukemia, one lymphoma in a patient who had malignant lymphoma of the cervical lymph nodes, and one metastatic carcinoma. In the patient with the metastatic carcinoma, the primary lesion occurred in the rectosigmoid colon and the metastatic lesion appeared three weeks after abdominoperineal resection.

Discussion

From the foregoing study, it seems evident that the presence of a nodule in the substance of the upper lip should not be regarded as unimportant; on the contrary, such a lesion is likely to be a tumor of some significance. In our series, about 86% of such nodules proved to be neoplasms that required careful surgical removal and microscopic examination. Of the total number, 78% were found to be mixed tumors or cylindromas.

A mixed tumor can be satisfactorily eradicated by surgical enucleation, carefully carried out so as not to cut into the lesion, since it is usually well encapsulated. Should the growth be more or less adherent to the skin or mucosa, the skin or mucous membrane immediately overlying the tumor should also be excised. Incomplete removal of the growth leads to recurrence; the recurrent lesion is many times more difficult to eliminate surgically than is the original lesion.

Twenty-four mixed tumors in the upper lip compared to only two in the lower lip were

seen at the Mayo Clinic from the years 1944 to 1963, inclusive. Why the upper lip should be a more common site for the development of such a lesion is uncertain, but possibly the reason is related to the more complicated embryologic development of the upper lip.

Cylindromas of the upper lip are rare, but the possibility that a nodule in the substance of this anatomic structure is a cylindroma should be borne in mind so that wide removal can be carried out at the initial surgery. The data on cylindroma described in this paper illustrate the tendency for a tumor of this type to grow and metastasize slowly; consequently, there is a definite need for follow-up examinations over a long period.

Son (Harvey Cushing at Yale, 1887) to Father and Reply

"I have to again send a supplication to you for money. It seems as though you sent me just a day or two ago that $40 which, in making out my accounts last night, I find to be too small to pay my board bill for $12, which comes in every other Friday . . . I take the News—a daily which costs four dollars; it is almost a necessity as all the notices etc. are printed in it. I also take the Record, a biweekly for $1.50 and the Yale Literary Magazine for $3.00." Enclosed was an itemized expense account which included fifty cents for the "trunk to the depot," ten cents for carfare, twenty-five for breakfast, and twenty-five cents for a "chicken show."

A bone of contention was Harvey's participation in athletics. He was playing shortstop on the freshman baseball team, and when they were scheduled to play the Harvard freshmen, he wrote home for permission to play.

The reply came: "Dear Harvey, I will try to reply to your letter calmly, though I do feel sore and disturbed over the unhappy position you have brought us into. I carefully explained before you went to New Haven, that we were going into a partnership with mutual responsibilities and duties. I was to supply the means, and you to conduct yourself to my approval while the partnership survived. Among the conditions I insisted on, and which I understood you to assent to, were those that you would not smoke, drink or be guilty of any immoral conduct or join a College ball club or boat crew . . ."

However, the doctor relented somewhat by adding that if the boy could not withdraw gracefully from the Harvard game, he would do no more about it, but "that must be the end of that sort of thing absolutely and for good."

The Chin

Chins are exclusively a human feature, not to be found among the beasts. If they had chins, most animals would look like each other. Man was given a chin to prevent the personality of his mouth and eyes from overwhelming the rest of his face, to prevent each individual from becoming a species unto himself.—*Malcolm Chazal*

Big men become big by doing what they didn't want to do when they didn't want to do it.—*Insurance Salesman*

An Analysis of 4000 Chemistry Graphs

Comments on Disease Patterns

RICHARD L. REECE, M.D.*
Minneapolis, Minnesota

I SHALL SAY a word or two about a referral laboratory's experience with 4000 serum survey chemistry graphs. In a few years, chemistry graphs, now generated by some 200 multichannel analyzers across the country, will be available to most doctors. My aim here is to acquaint practicing physicians with the graphs —what they are, how they are created, how many abnormal tests they detect, and what patterns certain conditions give. I will emphasize patterns, for, by recognizing these, physicians can diagnose unsuspected diseases.

What Chemistry Graphs Are

Multiple Channel Autoanalyzers** simultaneously measure 12 serum substances and record their concentrations on a moving chart. Analyzers come in two types—a "Hospital Model" and a "Survey Model." Hospital models analyze for serum electrolytes and eight other serum components. Survey models run the same eight tests but substitute for electrolytes these tests: lactic dehydrogenase, glutamic oxaloacetic transaminase, inorganic phosphorus, and cholesterol (Figure 1). We use the survey model (Figure 2), and the data I shall present concerns only survey chemistry graphs.

How Graphs Are Created

How do multiple channel analyzers work? They operate on the principle of continuous flow analysis. Let me briefly summarize this process. The analyzer aspirates two or three millimeters of a serum specimen; splits it into 12 streams which flow through a series of parallel plastic tubes; separates by air bubbles samples in each stream; mixes the dozen moving rivulets with reagents; passes some of the mixtures over a semipermeable membrane

*Fellow, American Society of Clinical Pathology; Pathologist, Lufkin Medical Laboratories and Automated Medical Laboratory.

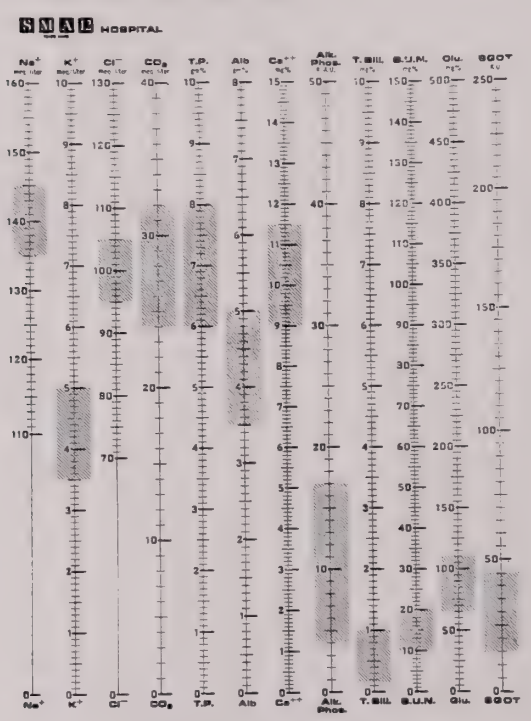
**Sequential Multiple Autoanalyzer (SMA-12, SMA-12/60), Technicon Corporation, Ardsley, New York.

which dialyzes out diffusible compounds; and pumps specimens to mixing coils or to heating baths where colors develop. Downstream, the 12 colored solutions move through a flow cell colorimeter which measures light absorbed by each color. Then a pen trailing red ink traces concentrations of all serum substances on a revolving chart. From this chart (a series of chemistry graphs separated by perforated lines) technologists tear off individual graphs, photostat them, and send originals to referring physicians.

How Many Abnormal Tests Graphs Detect

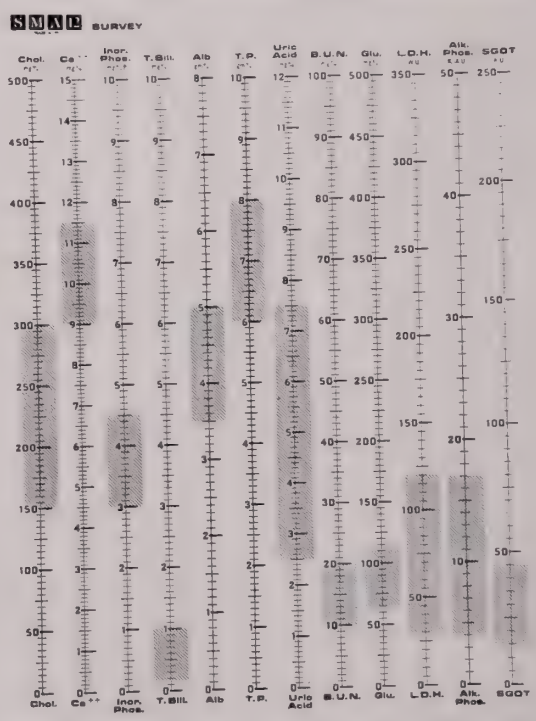
Among the 4000 specimens referred to our laboratory, 37.5 percent came from hospital patients, the rest from office patients. I mention types of patients because normal ranges and number of abnormal chemical tests will vary with the nature of the patient population. We mostly analyzed sera from patients with known or suspected disease—not from normal subjects in good health.

To arrive at normal ranges, we plotted the cumulative data for each test on gaussian* probability paper. This statistical method allowed us to calculate normal value data without testing large groups of normal subjects.[1] In Table 1, I list normal ranges estimated this way and record percent of abnormal tests. Table 2 indicates the number of normal graphs among the 4000 we produced. It also discloses the percent of graphs that had one, two, three, or four or more abnormal tests.



*See Test Your Word Score Page 375.

Disease Patterns



When a physician picks up a chemistry graph, he can quickly see what tests are abnormal. When two or more are abnormal, these sometimes form a pattern which may provide clues that will indicate what further information he should seek. Now I shall discuss certain conditions and show their graph patterns.

Pernicious Anemia

In pernicious anemia, marrow megaloblasts house large stores of lactic dehydrogenase, and red cells hemolyze more easily than normally. These factors probably cause serum lactic dehydrogenase to rise. In our series, I know of four cases of untreated pernicious anemia.

Chemistry Graph with electrolytes

Survey Chemistry Graph with cholesterol, inorganic phosphorous, uric acid, and lactic dehydrogenase instead of electrolytes.

Fig. 1—Two types of chemistry graphs produced by Sequential Multiple Autoanalyzers. The shaded bars indicate the normal range for each test.

TABLE 1

Tests	Normal Ranges: Probability curves	Normal Ranges: Values on Chemistry Graphs	Percent of Abnormal Tests: Low	Percent of Abnormal Tests: High
Cholesterol (Chol)	150-304	150-300	2.0	4.0
Calcium (Ca++)	8.7-10.7	9.0-11.5*	2.5	2.2
Phosphorus (Nor. Phos.)	2.6-4.5	3.0-4.5*	1.3	2.7
Total Bilirubin (T.Bili.)	0.2-0.8	0.2-1.0	....	5.2
Albumin (Alb.)	2.8-4.4	3.5-5.0	8.7	....
Total Protein (T.P.)	6.0-7.9	6.0-8.0	4.9	2.1
Uric Acid	2.5-7.6	2.5-7.5	....	11.0
Blood Urea Nitrogen (BUN)	8-25	10-20	0.5	9.2
Glucose (Glu.)	75-126	70-110	0.5	10.5
Lactic Dehydrogenase (LDH)	40-117	30-120	....	8.9
Alkaline Phosphatase (Alk Phos)	5-15	5-17		10.4
Serum Glutamic Oxaloacetic Transaminase (SGOT)	11-40	15-45	....	7.2

Abnormal tests among 4000 survey chemistry graphs. The percent of abnormal tests refers to those tests that were outside the normal ranges estimated on probability paper. *Recently, the Technicon Corporation announced that after "field trials," they are changing the normal range of calcium to 8.5 to 10.5 mg% and the normal range of phosphorus to 2.5 to 4.5 mg%.

In each, lactic dehydrogenase went off the upper end of the chart, i.e., levels exceeded 350 Wacker-units, and in each serum bilirubins hovered between 1.2 and 1.5 mg% (Figure 2).

Serum lactic dehydrogenase levels in pernicious anemia surpass those found in any other condition. Levels go up exponentially as hemoglobins fall, but enzyme values will rapidly decline when patients respond to B_{12}. After the physician starts B_{12}, he can expect serum lactic dehydrogenase levels to fall 50 percent in five days.[2]

One other patient whose serum we analyzed manifested a high lactic dehydrogenase and a slightly elevated bilirubin. She had a hemolytic anemia from a glucose-6-dehydrogenase defect. Hemolytic anemias of any cause will result in high lactic dehydrogenase levels. We recorded 12 other lactic dehydrogenases over 350 Wacker-units, but all sera had multiple other abnormal tests because patients had diseases such as myocardial infarction, liver necrosis, or metastatic tumor.

Although we have not seen graphs from definite cases, pulmonary embolism will almost always elevate serum lactic dehydrogenase and sometimes raise the serum transaminase and serum bilirubin. Amador and Potchen reported 41 patients who, by their symptoms, signs, and lung scans, had pulmonary emboli.[3] Forty of these showed high lactic dehydrogenases, while one half exhibited elevated

TABLE 2

Number and percent of normal and abnormal graphs among 4000 tested on Survey Sequential Multichannel Autoanalyzer.

	Number	Percent
Normal Graphs	2104	52.6
Abnormal Graphs		
one abnormal	1005	25.1
two abnormal	492	12.3
three abnormal	212	5.3
four or more abnormal	107	4.7
Total	4000	100.0

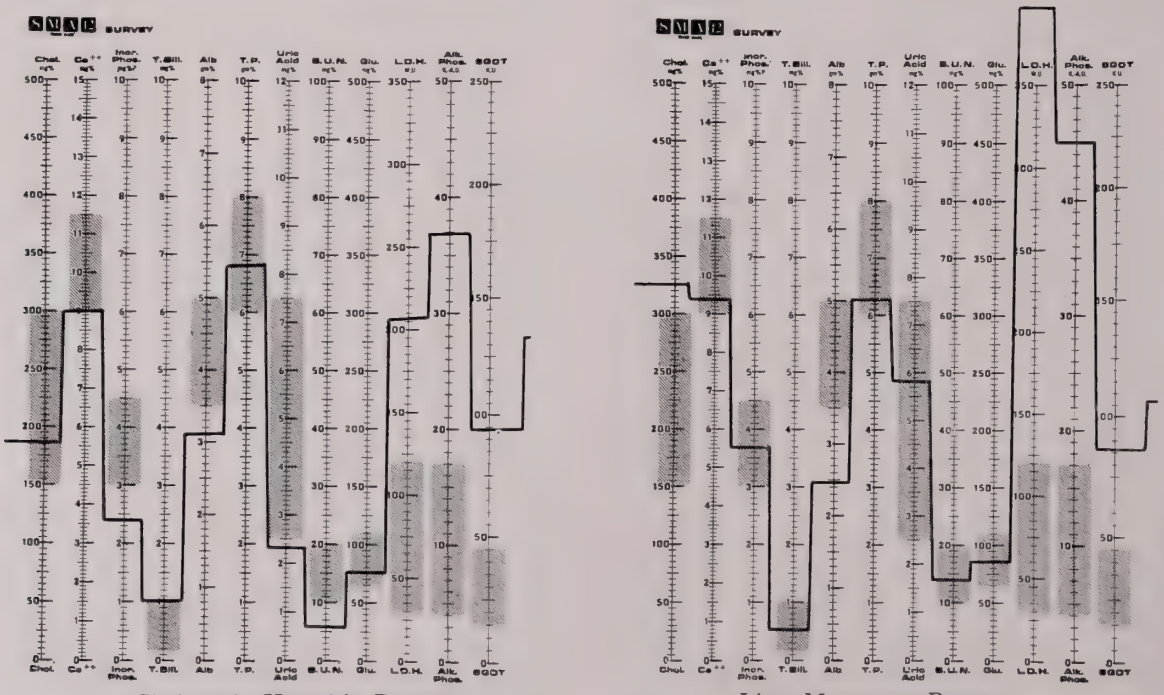
Pernicious Anemia Pattern

Fig. 3—Chemistry graph pattern from 68-year-old man with a macrocytic anemia with a hemoglobin of 3 Gm %. He had a megaloblastic marrow and responded to B_{12}.



bilirubins and one third had high transaminases.

When blood hemolyzes, red cells, rich in lactic dehydrogenase, discharge their contents into the serum. If hemolysis visibly tints a serum, we so indicate on the graph and tell physicians to disregard the lactic dehydrogenase value.

Liver Disease

As a measure of liver function, serum survey chemistry graphs excel. Why? Because they provide seven tests—total bilirubin, albumin, total protein, alkaline phosphatase, lactic dehydrogenase, glutamic oxaloacetic transaminase, and cholesterol—that relate in some way to the liver; and they provide them at a reasonable cost in a readable form.

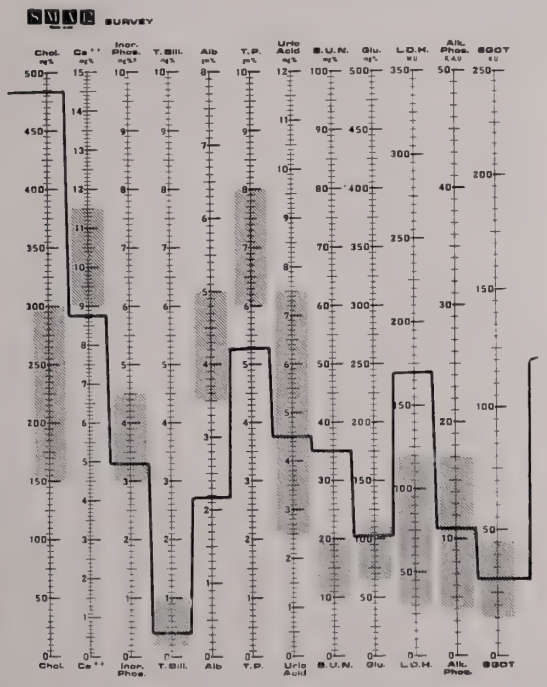
We have examined patterns of many types of liver disease, among them, portal cirrhosis, viral hepatitis, infectious mononucleosis with liver involvement, "lupoid" hepatitis, drug cholestasis, extrabiliary obstruction, metastatic tumor, and liver necrosis. Graphs alone will not differentiate these lesions. History counts. Physical examination counts. X-rays count.

Cholestatic Hepatitis Pattern

Liver Metastases Pattern

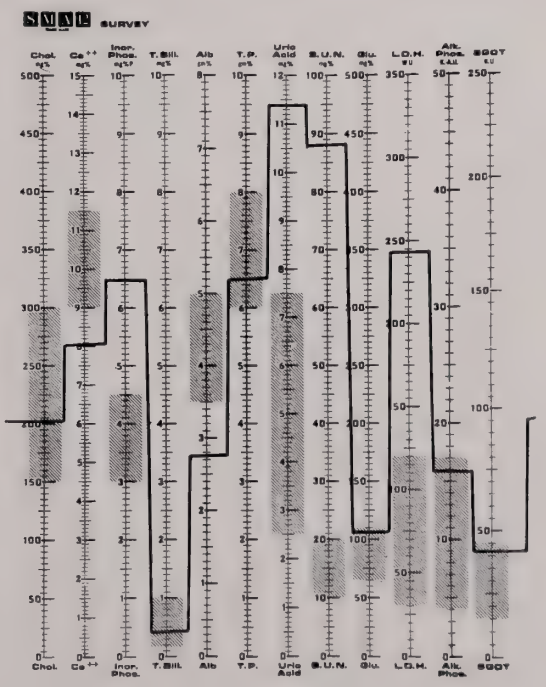
Fig. 4—Graph on left shows serum changes in a 29-year-old woman who had serum hepatitis after transfusion. Serum graph on the right was from a 57-year-old woman with colon cancer which had produced large nodules in the liver. When metastatic masses occupy a large part of the liver, both lactic dehydrogenase and alkaline phosphatase usually go up.

So do other blood tests. Even then a needle biopsy or exploratory laparotomy may be necessary to reach a diagnosis.



The high incidence (10.4 percent) of elevated alkaline phosphatases in our series exists partly because physicians frequently ordered the graphs to evaluate liver function. Although cholestasis from hepatitis, drugs, and tumor or stone obstruction usually produced these phosphatase elevations, we were also impressed that liver metastases could give rise to high levels and that patients with florid cirrhosis or fatty metamorphosis commonly had high alkaline phosphatases—a phenomenon observed by others.[4] The graphs in Figure 4 show two instances in which chemistry graphs helped solve diagnostic problems.

Kidney Disease



Three hundred and seventy-four or 9.2 percent of our 4000 graphs had blood urea nitrogens of greater than 25 mg%. How does this compare with other surveys? Of 2001 physicians screened at the 1966 American Medical Association Convention, six percent had blood urea nitrogens of 25 mg% or greater.[5] And of 1,080 patients tested in a practitioner's office in Columbus, Ohio, 10 percent had elevated urea nitrogens.[6]

We also observed ten urea nitrogens of 5 mg% or less. These occurred in dehydrated patients who were receiving large volumes of intravenous fluid. At Grace New Haven Hospital, Gallagher and Seligson reported blood urea nitrogens of 5 mg% or less occurring in about one percent of 16,000 tests.[7] They commented that low values in patients being infused with copious amounts of fluid implied good kidney function and a good prognosis.

In some situations, the physician with chemistry graphs can discern the nature or stage of kidney lesions. For instance, we have seen seven graphs showing severe hypoalbuminemia and hypercholesterolemia, the two serum changes that regularly occur in the nephrotic syndrome. Also we have observed 15 chronic renal failure patterns. These patients' sera showed an increased blood urea nitrogen (average 87 mg%), high phosphorus levels (average 6.0 mg%), hypoalbuminemia (average 2.8 mg%), hypocalcemia (average 8.6 mg%), low normal total protein (average 6.2

Nephrotic Syndrome Pattern

Chronic Renal Failure Pattern

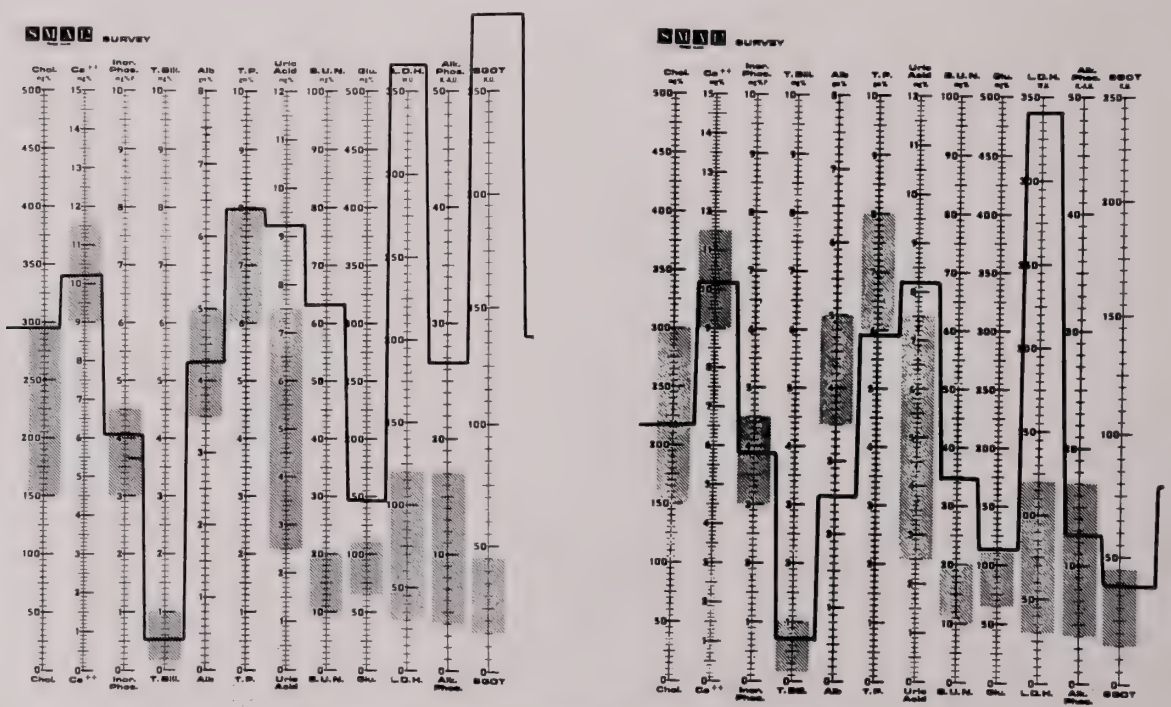
Fig. 5—The patient whose serum patterns appear on the left was 40 years old, had a recent bout of glomerulonephritis, and was spilling 4.1 grams of protein a day in his urine. On the right, the patient from whom this was drawn had chronic glomerulonephritis. He died a few days later and also showed a myocardial infarction about ten days old.

mg%), and hyperuricemia (average 10.4 mg%).

Late in renal insufficiency serum phosphorus increases, because phosphate clearance decreases. The mechanism of hyperuricemia is not as clear, but according to investigators at Columbia who studied 217 patients with renal hypertension, uric acid levels increase progressively as blood urea nitrogens exceed 41 mg%. Sixty-seven percent of their hypertensive patients receiving thiazides were hyperuricemic. Our data confirms that serum uric acid increases as blood urea nitrogen rises (Table 3).

TABLE 3

Blood Urea Nitrogen	Hyperuricemic > 7.6 mg%	
	Number	Percent
0-25 mg%	308-3692	8.3%
25-35 mg%	60-224	26.8%
35-45 mg%	36-42	85.6%
> 45 mg%	36-40	90.0%
	440-4000	11.0%



Increase in incidence of hyperuricemia among 4000 survey chemistry graphs. As blood urea nitrogen levels exceed 25 mg%, the incidence of elevated uric acid progressively rises.

Myocardial Infarction

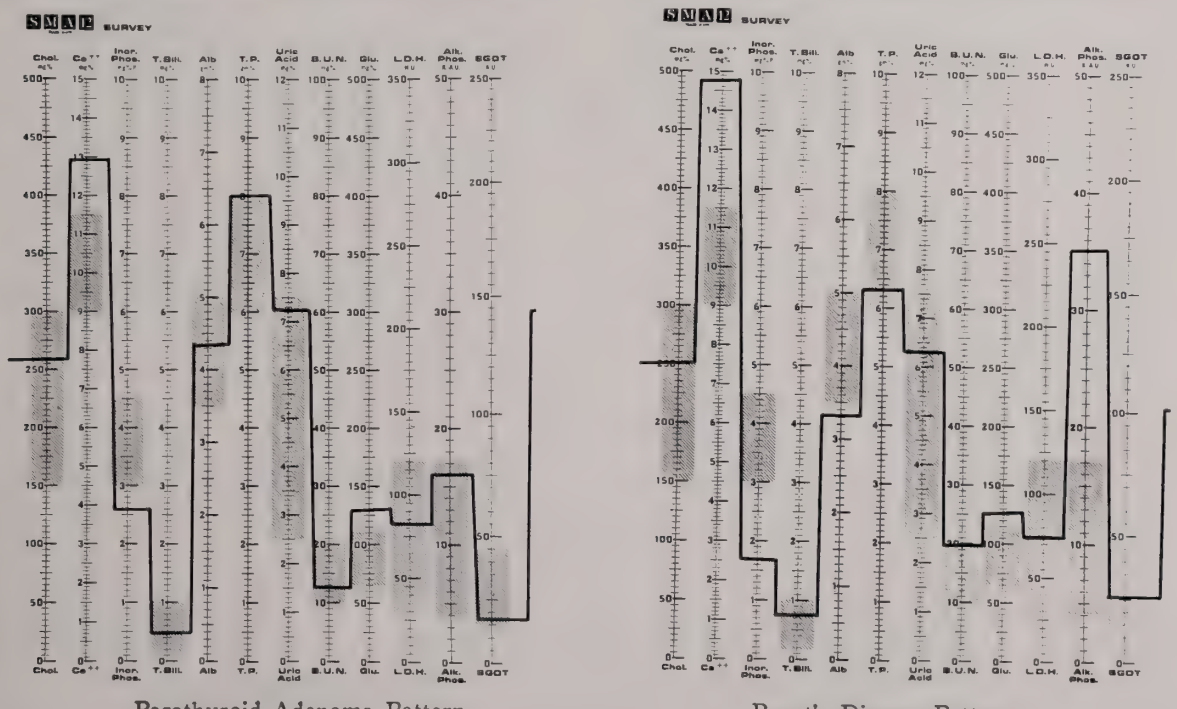
Patients who suffer myocardial infarctions have high serum glutamic oxaloacetic transaminases and lactic dehydrogenases. Physicians, of course, know this. But they sometimes do not appreciate how quickly these enzymes rise and how long they remain elevated. Transaminase goes up six to 12 hours after chest pain starts, peaks at 24 hours, and usually drops to normal in four to five days. Lactic dehydrogenase may not rise for twelve hours, reaches its peak at two to three days, and may not descend to normal for 10 days to two weeks. By using two enzyme tests, physicians can better gauge when infarction occurred, how extensive it is, and whether it is progressing (Figure 6). Also graphs may show if the patient is hypercholesterolemic, diabetic, uremic, or if he has a congested liver with abnormal function tests. This information may help the doctor to assess the patient's prognosis and manage him later.

Hypercalcemic States

With serum surveys, physicians can sort out

Patterns of Acute and Recent Myocardial Infarctions

Fig. 6—Graph on left is from a 70-year-old diabetic male with azotemia (note uric acid elevation) whose heart had infarcted 20 hours before. Graph on right is from a 51-year-old man with known gout who had suffered infarction eight days before. His transaminase had returned to normal on the fifth day.



those patients with hypercalcemia and, in a few cases, track down the cause. High serum calciums occur in many diseases, but other tests on the graph—phosphorus, alkaline phosphatase, blood urea nitrogen, and total protein—will usually help to limit the differential diagnosis to a few possibilities.

Foremost among diseases causing hypercalcemia is hyperparathyroidism—a curable condition which usually results in a low serum phosphorus. In our 4000 graphs we know of one patient who had a parathyroid adenoma excised because of a high calcium (12.9 mg%) and a low phosphorus (2.5 mg%) (Figure 7). About one patient in a thousand will have an adenoma. At an Indiana Medical Clinic, Drs. Boonstra and Jackson screened with an autoanalyzer the sera of 25,847 patients.[9] As a result of high calciums that the autoanalyzer detected, surgeons excised adenomas from 26 patients.

Of what help are the alkaline phosphatase, urea nitrogen, and total protein? In older patients with hypercalcemia, high alkaline phosphatases may mean Paget's disease, metastatic tumor, myeloma, or a malignant tumor which secretes a parathyroid hormone-like substance. Also it may signal the presence of vitamin D intoxication, a sarcoid, or a fracture. Before I leave alkaline phosphatase, a word of caution about interpreting the test in the young. Children, especially rapidly growing adolescents, normally have elevated alkaline phosphatases, sometimes up to 50 King-Armstrong units.

What about high blood urea nitrogens with hypercalcemia? If high serum calcium levels persist in a patient, they affect kidney function. Sustained hypercalcemia decreases the glomerular filtration rate, interferes with renal concentration, leads to urinary calculi, and may culminate in renal failure. We have seen only two graphs with calciums exceeding 15.0 mg%. In both ureas nitrogens were greater than 100 mg%, phosphoruses were over 7.0 mg%, and uric acids exceeded 10 mg%.

What does the total protein level mean to the clinician when his patient has hypercalcemia? First, if the protein is up, it may tip him off that the patient has diseases such as multiple myeloma, sarcoid, or lymphoma. Rarely Addison's disease or hypercalcemia of

Parathyroid Adenoma Pattern

Paget's Disease Pattern

Fig. 7—Left graph is from a 60-year-old man with a history of repeated kidney stones and mental depression. After the graph disclosed this pattern, he had a parathyroid adenoma excised. Graph on right is that of an 83-year-old woman with Paget's disease. Serum calcium rarely goes up in Paget's disease unless a patient is immobilized, but the alkaline phosphatase is invariably high if Paget's involves a significant fraction of the skeleton.

infancy will have associated high serum protein levels. Second, with a total protein determination physicians can better judge the significance of calcium levels. One gram of protein (either albumin or globulin) binds about 0.8 mg. of calcium.[12] When the total protein decreases, so does the calcium. For example, a patient who has a calcium of 10.2 mg% and a total protein of 5.0 mg%, is probably hypercalcemic.

Concluding Remarks

I have discussed how chemistry graphs can assist physicians in differential diagnosis. Because I wished to be brief, I did not deal with diabetes mellitus, gout, or hypercholesterolemia. But physicians may wish to screen for all three since they may forewarn of arteriosclerosis and its consequences.[10,11] Nor did I dwell upon patterns produced by endocrine diseases, malignancies, collagen diseases, myeloproliferate disorders, or inflammatory conditions—although all may produce recognizable patterns.

Finally, I have not mentioned two important problems of multiple channel analysis—specimen control and quality control. I will emphasize them now. As in manual tests, hemolyzed, lipemic, dysproteinemic, and old sera, or specimens from nonfasting patients, can mislead the physician. After a patient has eaten, glucose levels may rise and phosphorus levels tend to decline. Also if a patient has lipemia after a fatty meal, serum turbidity interferes with colorimetric readings and can give multiple spurious results. When this occurs, we notify the physician and tell him to draw another specimen.

In nonrefrigerated specimens over 48 hours old, glycolysis rapidly takes place. Indeed, glucose values may approach zero. Moreover, glucose values drop in a few hours in sera allowed to remain in contact with the clot. Also, when sera are exposed to light, bilirubin values slowly decline. These events, of course, also affect results of manual tests done singly. The chances for their being noticed, however, are greater when 12 test results are displayed at once.

So much for specimen control. Now a comment on quality control. To standardize and control the quality of tests, we daily run commercial sera with known low, average, or high results through the analyzer. Also we use a standard after every fifth sample to assure that no electronic drift occurs, and we plot data on quality control charts after each day's run. These approaches have proved satisfactory.

Summary

I have reviewed the experience of a referral laboratory with 4000 serum survey chemistry graphs. On these graphs, twelve channel autoanalyzers record the concentrations of cholesterol, calcium, phosphorus, albumin, total protein, bilirubin, uric acid, urea nitrogen, glucose, lactic dehydrogenase, glutamic oxaloacetic transaminase, and alkaline phosphatase. Of the 4000 graphs, 1896 or 47.4 percent showed at least one abnormal test. Tests most frequently abnormal included uric acid (11.0 percent), glucose (10.5 percent), alkaline phosphatase (10.4 percent), urea nitrogen (9.2 percent), and lactic dehydrogenase (8.9 percent). Chemistry graphs can help physicians to detect and assess pernicious anemia, liver disease, renal insufficiency, myocardial infarction, pulmonary embolism, diabetes mellitus, gout, hypercholesterolemia, malignancies, and other conditions.

Acknowledgment

I thank Miss Diane McKee for gathering the data and Mr. Robert Cooper and Dr. Wayne Chadbourn for reading the manuscript.

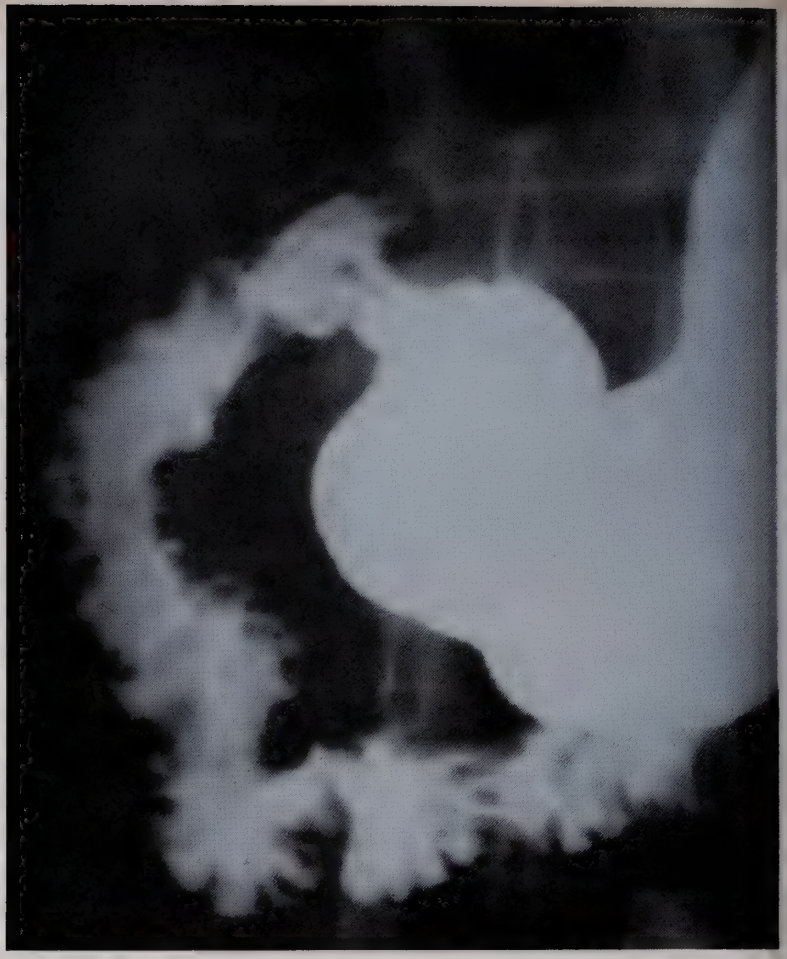
DERIVATIVELY SPEAKING

Pylorus—from Greek *pyle* (gate) plus *ouros* (guard).

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.



Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

Conventional Radiography

The restless duodenum makes radiographic diagnosis difficult, uncertain and often unproductive: Is this duodenum abnormal?

Hypotonic Duodenography

Pro-Banthine-induced duodenal calm permits full anatomic appraisal: Same patient. Duodenal normality is now evident.

- **in diagnosis**
- **in treatment**

Pro-Banthine® brand of propantheline bromide

calms the gastrointestinal tract

For fifteen years Pro-Banthine has been the most widely used anticholinergic agent in disorders of gastrointestinal motility and gastric hypersecretion. More recently Pro-Banthine has reestablished its pharmacologic effectiveness in diagnostic procedures using intragastric fibroscopy and hypotonic roentgenography.

How the X-rays were taken

In the hypotonic duodenograph[1,2] reproduced above, the gastrointestinal tract was relaxed with Pro-Banthine. The duodenum was intubated. Pro-Banthine in a dose of 60 mg. intramuscularly was used to assure prompt aperistalsis and double-contrast visualization was achieved with ordinary barium and air.

The same pharmacologic efficiency has proved of pronounced value in such conditions as: *peptic ulcer, pylorospasm, biliary dyskinesia, functional hypermotility and irritable colon.*

Contraindications: Glaucoma or severe cardiac disease.

Precautions: Since varying degrees of urinary hesitancy may occur in elderly males with prostatic hypertrophy, this should be watched for in such patients until they have gained some experience with the drug. Although never reported, theoretically a curare-like action may occur with possible loss of voluntary muscle control. Such patients should receive prompt and continuing artificial respiration until the drug effect has been exhausted.

Side Effects: The more common side effects, in order of incidence, are xerostomia, mydriasis, hesitancy of urination and gastric fullness.

Dosage: The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthine (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg. The parenteral dose should be adjusted to the patient's requirement and may be up to 30 mg. or more every six hours, intramuscularly or intravenously.

Artificial Heart

A RESEARCH and development program supported by public funds and directed by Dr. Frank Hastings of NHI is part of an international effort to develop an artificial heart. The hoped-for outcome would include improvements in the perfusion pumps employed during open heart surgery and in assist devices to relieve an overburdened or damaged heart, as well as a pump to replace the heart altogether. The research which is being conducted in commercial, university and government laboratories covers such things as basic research on pulsatile and non-pulsatile flow in living vessels, the microscopic behavior of blood particles in flow, the response of blood and tissue to foreign materials and unusual processes, biological and/or implantable energy sources and control systems for maintaining a balanced perfusion. It also includes the designing and testing of actual pumping devices.

Many goals of the artificial heart program appear within the capabilities of modern technology. The response of the living animal, however, and in particular the response of blood to prolonged exposure to foreign materials and unusual processes is not now known. Success of the artificial heart program therefore depends strongly on efforts to find materials and processes that keep blood trauma within tolerable limits.

At present hemolysis and platelet excitation are studied as a means of measuring the acceptability of a material or process in an artificial organ. An example of the kind of tolerances permitted in the former can be gained from the work of Dr. Eugene Bernstein and his colleagues in the Department of Surgery, University of Minnesota. Dr. Bernstein finds that if the imposed trauma causes sufficient intra-vascular hemolysis to cut the life spans of the red cells in half, his experimental animals succumb from renal blockages. This gives a threshold of tolerable pump-induced trauma of 0.1 mg. hemoglobin released into the plasma per 100 cc. of blood pumped by the heart. Some of the hemolysis caused by the pump occurs immediately within the pump; some occurs later as a consequence of pumping. There is evidence that a large number of pumps presently available can produce an index of hemolysis below the above threshold if only the immediate hemolysis is considered. However, experimental animals undergoing prolonged perfusions with these pumps succumb to the cumulative effect of delayed hemolysis. Additional work is required in order to find the causes and suggest cures for the delayed effect.

There is a correlation in the in-vitro tests between immediate hemolysis and auto-hemolysis during sterile incubation at 37° C. It is presently believed therefore that a pump producing a low index of immediate hemolysis will produce a correspondingly low delayed hemolysis. Thus the research on immediate hemolysis can be used to obtain an idea of the

probable cause of delayed destruction of red cells. Current work in the mechanical engineering laboratories at the University of Minnesota in cooperation with Dr. Bernstein show that if care is taken to avoid bubble formation, the flow processes in an artificial heart can be absolved of contributing to immediate hemolysis. In other words, turbulence, shear, and pressure fluctuations, in the absence of foreign surfaces, do not contribute to immediate hemolysis until very high velocities (2000 cm/sec.) are reached. In tests on different materials it is found that siliconizing the material can temporarily reduce and in some cases eliminate immediate hemolysis. It is believed that hemolysis in artificial organs occurs primarily due to interactions between blood and foreign surfaces. Similar conclusions have been reached in regard to platelet excitation. It would seem, then, that research on materials and the way flowing blood reacts with them physically and chemically holds the key to future successes in the development of artificial internal organs.

In the January and February issues of MINNESOTA MEDICINE there is a paper by Rafferty, Kletschka et al.* on a pump suitable for meeting some of the requirements of the artificial heart. The idea of a viscous flow impeller is an interesting one and should minimize damage to cells remote from the walls. The impeller shown in Figure 5 of Rafferty's paper was patented by N. Tesla in 1913. Its application as a heart replacement was first suggested in a paper by F. Dorman in 1965. The paper by Rafferty, Kletschka et al. illustrates several points worth stressing. If steady flow can be tolerated, an assortment of extremely simple, durable, and efficient pumps, with a range of flow rate-pressure head characteristics, can be designed employing conventional fluid mechanics design techniques.

In designing any pump the fluid properties must be considered. For the fluid properties of blood to give the desired pressure-flow relationships, consideration need be given only to the blood's viscosity (approximately four times that of water at pump conditions) and density. However, in the design of the equipment to minimize hemolysis (or clot formation) the minimum number of red cell wall encounters should occur, but there is not yet enough known to instruct the designer how to do this. The Rafferty team was able to keep hemolysis low by siliconizing the surfaces, but experience shows that this is only a temporary measure, as the siliconized surface elutes and hemolysis increases with time. If a stable non-traumatic surface can be developed, the pumps described will clearly be interesting candidates for future experiment and perhaps ultimate clinical use.

A final point should be made regarding the turbine pump. Although the appearance bears no resemblance to the natural heart and although its flow and pressure output is steady, instead of pulsatile, it is thought by some to be capable of accomplishing the function of the heart—that of maintaining adequate perfusion.

This leads to speculation on how other desirable functions might be attained by organs that do not resemble natural organs or, indeed, by organs that have no natural counterparts.

In this, the infancy of artificial internal organs, the artificial heart appears almost within reach. When the fundamental nature of blood-foreign material interactions is finally understood and controlled, the prospects for improving the physical well-being of man will be very exciting indeed.

Sensori-neural Hearing Loss

DR. WALSH* has discussed the more general causes of the serious and common medical problem, sensori-neural hearing impairment. There are many instances of this type of hearing loss in which the cause is still unknown. Recent advances in the surgical treatment of conductive hearing impairment have been dramatic but, unfortunately, in a small number of patients undergoing this type of surgery a complete sensori-neural hearing loss develops for which there is no treatment. The most common reconstructive operation, stapedectomy for otosclerosis, carries a 1 to 2.5% risk of profound sensori-neural hearing loss.[1] The risk is not great in comparison with the high percentage of patients whose hearing is restored to a socially adequate level, but when the complication does occur it is tragic. If one considers that thousands of patients have had reconstructive ear surgery for conductive hearing impairment and that thousands will have such operations in the future, it can be anticipated that there will be a formidable number of patients with iatrogenic sensori-neural hearing loss. The incidence of sensori-neural hearing impairment following stapedectomy can be reduced[1] by the selection of patients for surgery who have not previously had stapes operations or other problems that increase the risk of cochlear injury; by careful sterile technique and appropriate prophylactic administration of antibiotics; by the selection of the safest stapes replacement prosthesis; and by having the surgery performed by an experienced otologist.

Most of our attention in the last 15 years has been focused on the surgical treatment of conductive hearing loss. Although advances in the management of sensori-neural hearing impairment have been slight, nevertheless some progress has been made.

Investigation and Education

Through the efforts of such organizations as the Deafness Research Foundation, the John Tracy Clinic, and the Pre-School Medical Survey of Vision and Hearing, both the medical profession and the public are being informed of the problem of deafness and what can be done for those afflicted. Through the establishment of temporal bone banks throughout the country and the support of otologic research, knowledge is being accumulated regarding the cause, prevention, and treatment of sensori-neural hearing impairment.

Prevention

Excellent prenatal, perinatal, and neonatal care is the first step in the prevention of sensori-neural hearing loss. Care should be taken to see that the mother is not exposed to rubella or any other viral infection during pregnancy. The pregnant woman should not be given potentially harmful drugs. Rh incompatibilities that can lead to erythroblastosis fetalis should receive the utmost attention, and anoxia of the infant at birth should be avoided. The infant should receive a proper program of immunization, and all ear infections should be treated immediately and aggressively.

The recognition of potentially ototoxic drugs and the avoidance of their use is important in all age groups. I have seen patients who have received ototoxic antibiotics for relatively minor infections, with a resultant severe sensori-neural hearing loss, when a less toxic antibiotic would have been just as effective. There are, of course, life-threatening infections for which an ototoxic antibiotic is the only satisfactory treatment; but, before such an antibiotic is used, objective evidence justifying the treatment should be obtained by identifying the organism and by performing careful antibiotic sensitivity studies.

Some inner ears are more susceptible than others to injury from loud noise, but all ears are injured by excessively loud noise. The obvious solution is to control the ambient** noise or protect the patient against sound. It is much more difficult to control environmental noise than to protect the patient from noise. Some-

Think small. If you save one person from hunger, you work a miracle. Give to CARE, New York 10016

times this is such a serious problem that it requires a change in occupation for the patient. A common cause of progressive high-tone sensori-neural hearing loss in farmers in the midwest is long exposure to tractor noise. Tightly fitting ear plugs or ear muffs will protect against this ever-present problem. Once hearing impairment has begun as a result of exposure to excessive noise, ear defenders will help to prevent further loss.

A large number of head injuries resulting in hearing impairment occur in automobile accidents. Safety belts and other safety measures will definitely help to prevent deafness.

Medical and Surgical Treatment

Once a sensori-neural hearing impairment has occurred, only in rare incidences can the condition be alleviated by medical or surgical measures. There is some evidence that the rapidly progressive sensori-neural hearing loss that occurs in Cogan's syndrome,[2] collagen diseases,[3] and latent labyrinthitis as a result of congenital syphilis[4] can be stabilized and sometimes reversed by corticosteroid therapy when instituted early enough. Sensori-neural hearing impairment in adults due to hypothyroidism can often be reversed by use of thyroid extract.[5] There is also evidence suggesting that patients with a sudden sensori-neural hearing loss due to vascular embarrassment of the inner ear can be benefited if anticoagulant therapy is begun immediately.[6] In our hands, medical therapy has been disappointing in the treatment of sensori-neural hearing loss resulting from Meniere's disease. With or without medical therapy, there is usually a progressive deterioration in hearing, although initially the hearing loss does tend to fluctuate in severity. This is particularly alarming when one considers that both ears are involved in approximately 10% of the patients with this disease. Recent studies have revealed that surgical decompression of the labyrinth[7-9] offers hope of arresting progression of the hearing loss and improvement in the hearing in patients who are operated on early in the course of the disease.

When very small acoustic neuromas are identified, it is possible in a few cases to remove the tumor through a middle fossa approach to the internal auditory meatus while preserving useful cochlear function.

Rehabilitation

Once a permanent sensori-neural hearing loss has been established, rehabilitative measures must be instituted. Until recently, it has been the rule rather than the exception to first recognize that a child is hard of hearing when he is two years of age or older. Unfortunately, precious time in learning to communicate has been lost by then. With the introduction of auditory screening of the newborn[10] by a relatively simple test to identify tentatively those infants with significant hearing impairment and the development of cortical audiometry[11] which can accurately establish auditory threshold in the infant, it is now frequently possible to diagnose a serious hearing problem in the first few months of life. When residual cochlear function is demonstrated, the infant can be fitted with a hearing aid so that he will experience the sounds of his environment. Rehabilitation also involves extensive education of both the patient and his family and, when necessary, instruction in sign language and speech-reading. In addition, the child should be given special schooling preferably no later than the age of three years. The older child and adult will also benefit from these rehabilitative measures.

At this stage of our knowledge, means of managing sensori-neural hearing loss are extremely limited. We do know, however, that, depending on the circumstances, once a sensori-neural hearing impairment is evident, the earliest possible institution of preventive, therapeutic, and rehabilitative measures offers the patient the greatest chance of significant benefit.

Advantages and Limitations of a Hearing Aid

In presenting the advantages and limitations of a hearing aid, Dr. Carhart* has dealt simply and concisely with a rather complex subject. The question of whether or not to recommend a hearing aid is often diffcult to answer with confidence. The problem can be made somewhat easier and the answer more valid if one recognizes and applies the principles of hearing and amplification of sound along with a thoughtful evaluation of the patient as suggested in this article.

The discussion of the limitations of a hearing aid is particularly pertinent at a time when we are prone to think that the wonders of electronics can or should overcome all obstacles, including deafness. This simply is not the case at present, and there is no prospect of early developments that will surmount the major difficulties that Dr. Carhart mentions.

In evaluating the developments and changes in hearing aids over the past decade, we are faced with the indisputable fact that most of the improvements made have been in terms of size and convenience rather than in performance. It appears to be impossible at present to build the best quality amplifiers for most hard-of-hearing listeners in the tiny cases that are popular in current hearing aids. This frequently raises the question of what compromises should be made among performance, convenience, appearance, and cost. Because usually no single instrument can be proved superior for a specific person under all circumstances, the selection of a hearing aid is generally acknowledged to be a reasonable balance between objective tests of performance and a number of judgments on practical and personal aspects of the problem.

It usually is advisable, if not actually crucial, that a person considering a hearing aid for the first time have professional help in selecting a suitable instrument and in learning to use it optimally. Such help is becoming available to more and more people through the expansion of clinical and educational services in audiology. Most otolaryngologists and many other physicians either are active in providing and promoting such services or at least know where to refer patients for this kind of help. It is to be hoped that all physicians will share this knowledge and will practice appropriate referrals of patients seeking help with regard to hearing aids.

Effective Use of Serum Creatine Phosphokinase Assay*

The serum creatine phosphokinase assay was introduced into clinical medicine in 1959 by Ebashi and co-workers, who observed high activity of the enzyme in sera of patients with progressive muscular dystrophy. The current status and limitations of the serum creatine phosphokinase test and the possible significance of abnormal values are discussed in a recent review by Loegering and co-workers.[1] Since the enzyme is stored in high concentrations only in nerve tissue and skeletal and cardiac muscle, increase in serum creatine phosphokinase activity usually indicates enzyme release from one of these tissues as a result of destruction or excessive permeability of cells in these tissues; in-vivo or in-vitro hemolysis, hepatic disease, or pulmonary infarction does not result in high serum creatine phosphokinase levels.

Effective use of the creatine phosphokinase test requires a number of precautions. The normal range of values for the type of assay used by the laboratory must be known for adults and for infants of each sex. The reproducibility and sensitivity of the test are increased if –SH protecting agents, such as cysteine or glutathione, are added to the reaction mixture.[2,3] Unexpected high values may be observed in the recovery phase of diabetic acidosis, in chronic alcoholics after a binge, in the puerperium, and after prolonged and

heavy physical exertion.[3,4] Finally, high serum creatine phosphokinase levels may be observed in myxedema even when other clinical evidence of a myopathy is lacking; conversely, creatine phosphokinase levels are usually not increased in hyperthyroidism even when the condition is complicated by myopathy.[2]

The serum creatine phosphokinase levels are increased in 79% of the definite carriers of the Duchenne type of muscular dystrophy and in approximately half of the probable or possible carriers of this disease.[5] High levels are encountered in patients with the Duchenne type of muscular dystrophy early in the course of the disease, and the serum levels decrease as the disease advances, possibly due to reduction in total muscle mass. In other types of dystrophies the increases are less marked and less constant. A normal serum creatine phosphokinase level in a child who has shown clinical and electromyographic evidence of myopathy since birth suggests a congenital myopathy other than dystrophy, such as central core disease, nemaline (Z-disk or rod) myopathy, megaconial myopathy, or myotubular myopathy. In those rare cases of late-onset nemaline myopathy observed to date, the serum creatine phosphokinase levels were not increased.[6]

In inflammatory myopathies associated with acute destruction of muscle fibers there frequently is a pronounced increase of the serum creatine phosphokinase level. In these cases the decreasing levels of the enzyme may serve as a guide to the efficacy of corticosteroid hormone therapy, although improvement in muscle strength may not appear for several weeks after the serum creatine phosphokinase levels have started to decrease. In weakness induced by excessive corticosteroid hormone therapy, the creatine phosphokinase levels are usually not increased. In acute myocardial infarction or in myocardiopathies due to other causes, serum creatine phosphokinase and glutamic-oxaloacetic transaminase levels are both increased. However, the creatine phosphokinase values represent a more reliable index of myocardial damage because they are unaffected by passive congestion of the liver or by other types of hepatic disease that might coexist. It thus appears that, when carefully used, the creatine phosphokinase test represents a valuable and important diagnostic measure in clinical medicine.

Drug Therapy for Treatment of the Manic State*

THE HERALDING of a relatively new drug for the treatment of the manic state is noteworthy and long awaited. Probably no disease causes more pain, misery, despair, sadness, or torture to self and others than depression. It probably is the most frequently encountered, yet often least recognized, illness in the diagnostic domain of medicine.

Those who ply their trade in the nuances of mental illness know full well the frustration of

coping with the "manic" patient. His ability to deceive others and deny to himself the prodromal symptoms of his illness is of historic significance. Any new approach offered to treat the fulminating symptoms of mania is gratefully appreciated. Least of all it places an aggressive tool into the hands of the psychiatrist. Too often his role has been identified as passive and nonresponsive by himself and others, with neither party realizing that such a position is untenable in the "life game." A psychiatrist should be a good listener, but to listen well requires alertness, "savvy," and a comprehension of the unconscious; and such skills are not passively acquired. Mental activity implies motion, energy, and involvement. The acquisition of new drugs for the treatment of mental disorders will be acknowledged in the future more for their relatedness to etiology than for specific results in treatment, even if promising or successful, or both.

You May Be Right

While in Madagascar this past summer, working at the Manambaro Lutheran Hospital, I found schistosomiasis* to be a very common disease. To establish the diagnosis it is common to take a punch biopsy of the rectal valves. Frequently this led to severe rectal bleeding, difficult to control. Poor clotting mechanism was encountered occasionally, especially in patients with advanced liver damage. Cooperation of the patient wasn't always the best, and transfusions were sometimes difficult to do because of the lack of donors.

To circumvent this and still get an adequate biopsy I used an ordinary ring clamp with horizontal grooved edges. Using this instrument, it was possible to seize the rectal valve through an anoscope and close the clamp tightly, which then made it possible to remove a portion of mucosa caught in the jaws of the instrument. An adequate biopsy for examination without hemorrhage was readily obtained in this manner. I recommend this biopsy procedure for schistosoma ova, rather than the use of a punch-biopsy instrument.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

The Editor's Soliloquy

Family Physician

Almost from time immemorial the doctor has been dignified as Family Physician. Occasionally and affectionately he has been dubbed "Good Old Doc" or, in a more detached and sardonic vein, as bone-setter, medico, or one of the pill compounds: pillbag, pill-pusher, pill-shooter. In his capacity as surgeon he is sometimes aptly termed sawbones, a sobriquet first appearing in the literature when Charles Dickens used it in Pickwick.

After long investiture with the familiar and acceptable title of Family Physician, latter day modern bureaucratic advocates of a more dignified and upgrading name progressively graduated him to General Practitioner, GP and Generalist; and yet more recently to the more exalted Primary Physician.

The term Generalist was obviously designed to place the doctor in the category of the other "ists" (specialists). While Generalist has the advantage of compactness and euphony it lacks specificity, unless it were preceded by Medical.

Speaking of suffixes: -ian (obstetrician) grafted on to General would yield Generalian—so uneuphonious a hybrid that it would die aborning. As for the suffix -geon (surgeon): Generalgeon would be such an etymological monstrosity that its pronunciation alone would Nicodemus it into prompt retirement and oblivion.

How about the good old Greek suffix, -path? Homopath (homo plus path) would be excellent per se but, in the minds of the undiscriminating, would surely be confused with homeopath. Then how about omnipath (omnia plus path)?

We could go on and on—getting more and more abstracted in the semantic jungle of nomenclature. Why not just settle for Family Physician: an appellation comfortable and reassuring to our patients and an honorable title that has never been debased and that requires no enhancement. Why discard it in a will-o-the-wisp search for even higher terminology status. I can think of nothing more prestigious, more endearing and more honor-conferring than to be called the Family Surgeon, the Family Internist, the Family Physician.—

Carl O. Rice, M.D.

Old Doc Hess says—The left hand hand-shaker is the type of individual who, like a swimmer doing the Australian crawl, offers his hands alternately right and left as he moves toward his chosen guest of the evening.—C.O.R.

Our Own Fault?

Varicose veins are the result of an improper selection of grandparents.—*Osler*

Something for Nothing

Sometimes one pays most for the things one gets for nothing.—*Albert Einstein*

Always arise from the table with an appetite and you will never sit down without one.—*William Penn*

Landouzy-Dejerine Syndrome

This slowly progressive muscular dystrophy, which affects mainly the muscles of the face, shoulders, and pectoral girdle, was first described by Landouzy and Dejerine in 1885. The condition appears in late childhood or in adolescence. Both sexes may be affected as the syndrome characteristically is inherited and transmitted as a Mendelian dominant.

The most common initial symptom is inability to raise the arms above the head or keep them in that position. Some patients at an early age have difficulty in completely closing the eyes. The physical signs are those resulting from weakness and atrophy of the various muscle groups involved. First affected are the large muscles of the pectoral girdle, which eventually show marked atrophy. In more advanced conditions the atrophy results in a striking flattening of the entire anterior chest. The cheekbone and the face are also severely affected. Involvement of the cervical muscles is usually moderate, and there is atrophy in the suprascapularis and infrascapularis. A later development is atrophy of the erector spinae group of muscles and involvement of the deep muscles of the pelvis, producing an exaggerated lordosis with a waddling, rather grotesque gait. This peculiar walk is seldom associated with other conditions.

The course of this muscular dystrophy is usually benign. There may be long periods of remissions; and in some cases for reasons not known, the condition may eventually cease to progress. Only occasionally is a patient severely handicapped before reaching old age. No specific treatment is known. Various recommended nutritional supplements are of doubtful therapeutic value.

Bio-Dynamo-Chromatic-Diagnosis and Therapy

Whenever the irregulars in the healing art assemble for the purpose of exchanging trade secrets and telling each other how good they are, George Starr White, M.D., F.S.Sc. (Lond.), D.C., Ph.D., LL.D., Los Angeles, is among those present. He developed the fancy-name system that combines a lot of hocus-pocus—it seems one diagnoses disease by a "Sympathetic Vagal Reflex." To elicit the said phenomenon, the patient faces east or west and his abdomen is thumped until a dull area is found. Then colored lights are thrown on the abdomen and the thumping is continued. A ruby and blue light with associated dullness means one thing and a green light combination another.

In 1925, White produced the last word in this fancy business, the Rithmo-Chrome and Duo-Colors. He has a lot of books to sell and a lot of apparatus. For instance, in his latest announcement, Figure 10 shows a "person sitting on a Filteray Cushion and receiving Filtered Ultrared Rays while doing Rithmo-Chrome breathing and inhaling Oxygen-Vapor or Medicated Vapor and at the same time getting therapeutic effect of the magnetic forces of the earth, as he is grounded and facing exactly north and south." If the Duo-Colors are added to this, Dr. White affirms, the patient is certainly getting "Natural Methods Condenst." And if he isn't getting that, what is he getting?*

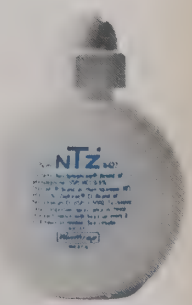
"The inconvenience of a cold"

For a cold, NTz® Nasal Spray provides rapid relief of nasal symptoms. Relief starts with the first spray which opens the inferior part of the common meatus. A second spray, a few minutes later, will shrink the turbinates to help provide sinus drainage and ventilation. Dosage may be repeated every three or four hours as needed, for temporary relief of symptoms. NTz is well tolerated but overdosage should be avoided.

As a sinusitis deterrent, NTz Nasal Spray can be used to keep the nasal passages open during a cold to help prevent development of acute sinusitis—or to help prevent the acute condition from becoming chronic.



Supplied: NTz Nasal Spray, plastic squeeze bottles of 20 ml.; NTz Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTz is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Winthrop Laboratories, New York, N.Y. 10016 Winthrop

Valium® (diazepam)
useful adjunct for the coronary patient...

When oppressive feelings and psychic tensions are severe and cooperation with the physician poor, it may be helpful to add adjunctive Valium (diazepam), 10 mg or 5 mg t.i.d., to the coronary patient's regimen. Valium (diazepam) helps to promote the needed relaxation that the patient requires to make him less preoccupied with his condition and more inclined to cooperate in, and benefit from, the total therapeutic program. Valium (diazepam) may be administered in the presence of secondary depressive symptoms.

in the hospital...
(5 mg – or 10 mg t.i.d.)

convalescing...
(2 mg or 5 mg t.i.d.)

The heart patient who leaves the hospital to enter a period of slow restorative treatment is often forced to make emotionally difficult adjustments. The resulting stress of this period may again cause psychic tension to mount to potentially harmful levels. To augment your reassurance and the emotional support of his family, a 2 mg or 5 mg t.i.d. regimen of Valium (diazepam) can reduce psychic tension and thereby help the patient to accept necessary restrictions more calmly, and to adjust to his illness more realistically.

back at work...
(2 mg or 5 mg t.i.d.)

Getting back to work presents additional stresses for the cardiac patient. There are often anxiety-producing features in the job which can be more significant than the physical or intellectual demands of the work. Valium (diazepam), 2 mg or 5 mg t.i.d., may be a useful adjunct to reduce overreaction to these stresses and thus help the patient to face job situations more calmly and rationally.

Valium® (diazepam)
to help relieve psychic tension

and for the patient with tension-induced sleeplessness, remember the value of an extra tablet at bedtime

Before prescribing, please consult complete product information, a summary of which follows:

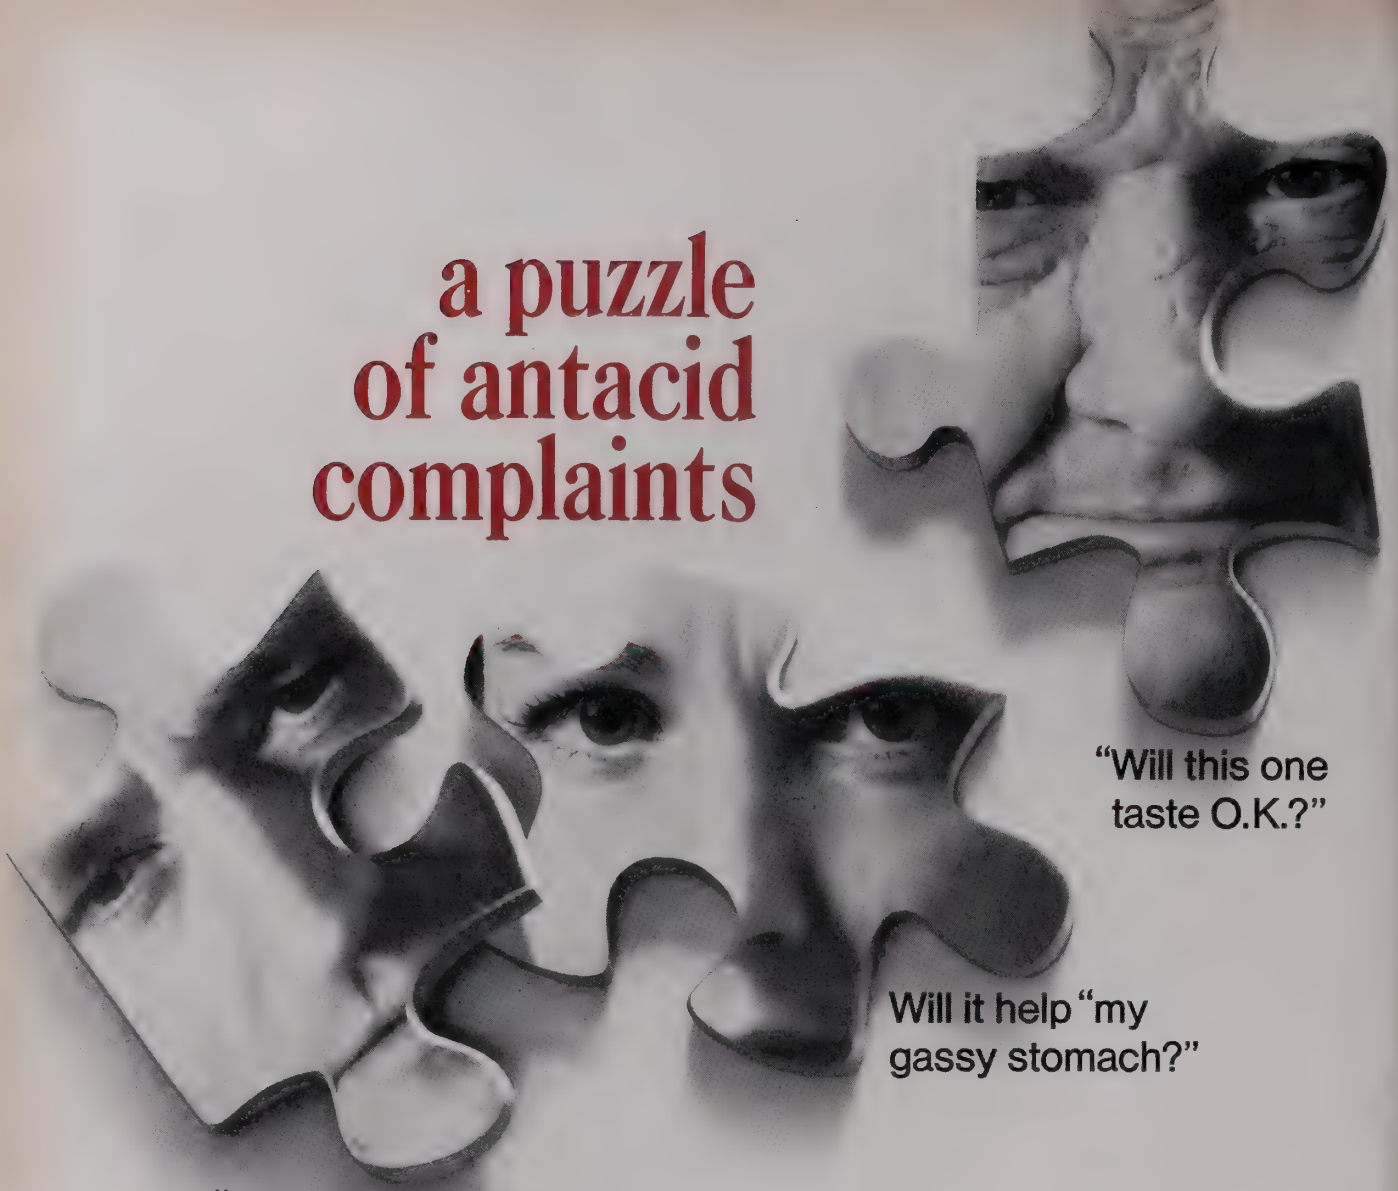
Indications: Tension and anxiety states, moderate to severe psychoneurotic states with anxiety, apprehension or agitation alone or with depressive symptoms; somatic complaints which are concomitants of emotional factors; acute agitation due to alcohol withdrawal; muscle spasm associated with cerebral palsy and athetosis.

Contraindications: Infants, patients with history of convulsive disorders, glaucoma or known hypersensitivity to drug.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly or debilitated patients (not more than 1 mg, one or two times daily initially) to preclude ataxia or oversedation, increasing gradually as needed or tolerated. As is true of all CNS-acting drugs, until correct maintenance dosage is established, advise patients against possibly hazardous procedures requiring complete mental alertness or physical coordination. Driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. If such combination therapy is used, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, barbiturates, MAO inhibitors and other antidepressants. Advise patients against simultaneous ingestion of alcohol or other CNS depressants. Safe use in pregnancy not established. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances, acute hyperexcited states, hallucinations); changes in EEG patterns during and after drug treatment. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms (convulsions, tremor, abdominal and muscle cramps, vomiting, sweating) similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.



Dosage—Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d.

Geriatric patients: 1 or 2 mg/day initially, increase gradually as needed and tolerated. (See Precautions.)

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 and 500.

a puzzle of antacid complaints

Mylanta®

aluminum and magnesium hydroxide *plus* simethicone

a solution to peptic ulcer distress

Effective neutralization—
with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

Concomitant relief of G.I. gas distress—
with the proven[1] defoaming action of simethicone.

Prolonged acceptance confirmed—
in 87.5% of 104 patients after a total of 20,459 documented days of therapy.[2]

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

Curbstone Consultation

Breathholding

QUESTION: While examining an eighteen-month-old child recently, I met with a great deal of resistance and negative behavior. The child became exceedingly angry and cried violently. Then he stopped breathing, became cyanotic, rigid, and momentarily unconscious for about one minute. Having never had such an experience, I write to inquire as to its meaning, cause, and how to deal with it.

ANSWER: This phenomenon was first described in 1848. Because of its relatively low incidence, little mention is made of it during medical school days and internship training. Clinical experience indicates that such behavior invariably is symptomatic of acute emotional distress arising from three primary sources: (1) disturbed parent-child relationships, (2) fear, or (3) pain. Age on onset is reported as being between six and eighteen months. The pattern rarely persists beyond four or five years. Unless the source of difficulty is defined and help is given, these spells often are replaced by temper tantrums or other behavioral disorders.

Since breathholding is rarely fatal, parents should be reassured to reduce their anxiety titer. Concomitantly, parental expectations of the child and their methods of managing him should be explored. If inappropriate, they should be corrected through counselling. In rare cases a period of separation —placing the child in a hospital—may be indicated.

Remedies Derived From The Poplar Tree

We have already mentioned, when speaking of the unguents, the use that is made of the berries of the white poplar. A potion prepared from the bark is good for sciatica and strangury, and the juice of the leaves is taken warm for earache. So long as a person holds a sprig of poplar in his hand, there is no fear of chafing between the thighs. The black poplar is looked upon as the most efficacious. The seed of it, taken in vinegar, is good for epilepsy. The leaves, boiled in vinegar, are applied topically for gout. A moisture that exudes from the clefts of the black poplar removes warts and pimples caused by friction.—*Pliny*

A Surfeit

I die by the help of too many physicians.—*Alexander the Great*

A New Tongue

During the fierce fighting of August 1943 a wounded soldier, Pyotr Sigayev, was brought to a field hospital. His life was in no danger, but the shrapnel wound caused great concern.

His head was a gruesome sight. Half his face was mutilated beyond recognition. The lower jaw was fractured in two places. All but four of his teeth were missing. Unintelligible sounds came from his lips. Sigayev's tongue was crushed. Mere rags of tissue remained in its place, and had to be cut out to the root at once under novocain anesthesia.

The patient was evacuated to Moscow. By the time he arrived at the Central Institute of Traumatology his condition had deteriorated. The tongueless man could not talk. What was worse, he could hardly chew or swallow.

At the institute the surgeons first tackled his shattered jaw. A month later, after the patient was somewhat fortified by artificial feeding, they risked an operation: All scars and adhesions in the vicinity of the fracture were cut, the jaw pulled forward to its normal position, and put in a plaster cast for six weeks.

After the lower jaw healed artificial dentures were attached to the four remaining teeth. This facilitated chewing. The splinters of the lower jaw were removed and the bone defects made up by a transplanted cartilage. Another cartilage graft helped to shape the chin.

There now remained the tongue. The only possible thing to do was to make a new one. The most suitable material for it was the skin; but a very large piece of it was required. It was to be taken from the patient's back. A round Filatov stalk was prepared under the shoulder-blade. But the skin alone was too thin to suit the purpose. The subcutaneous tissue and a layer of fat would have to go with it. That would make the stalk thick enough.

The graft was to take the shortest possible route to its destination. Transferred from the back to the belly, it was further transplanted to the arm. The patient had only to raise his arm to bring the stalk to his mouth.

The operation was completed in November 1946. The root of the tongue was sutured with silk thread and drawn out as far as it would go. Operating in the depth of the oral cavity was extremely difficult. The surgeons removed the scars from the surface of the tongue stump. The site was then ready to receive the Filatov stalk.

The end of the stalk was unrolled and inserted into the oral cavity, where it was sewed on to the upper and lower surface of the tongue root. Now one end of the stalk was implanted in the root, and the other remained on the arm.

For three weeks Sigayev's arm remained pressed to his mouth. To hold it in that position it was bandaged to the head. Surgeons kept constant vigil over their patient. All went well. The stalk took root. It was finally cut away three inches from the root. The smaller part of it remained on the arm, and was soon removed; the second part was in the mouth, grown firmly to the root, which had retained its original muscles. That was how a new tongue was made.

In two weeks Sigayev was mute no longer. His speech was perfectly intelligible.

This delicate operation, skillfully performed by Professor Mikhelson, was another triumph of Soviet plastic surgery.*

The Viewing Box

Vietnam Veteran

This is a 20-year-old negro Marine corporal who was admitted with a history of abdominal pain for 24 hours. He returned from Vietnam 10 months ago and has been in good health until this rather sudden onset of pain.

What is your diagnosis? (See next page).

Diagnosis: Ascariasis of the small bowel.

Ascaris is a parasite that is widely distributed throughout the world. It is of importance especially in pediatrics, because even one worm may produce a variety of clinical manifestations.

The adult worms measure 15 to 30 cm. in length and about 3 to 5 mm. in diameter. The eggs undergo an incubation period in the soil, after which they are ingested by the patient. Once in the small intestine the larvae are hatched, then penetrate the intestinal wall and reach the lungs by way of venules or lymphatics. In the lungs they can cause a pneumonia characterized by high fever, chills, cough, and bloody sputum containing larvae. From the alveolar spaces they migrate up the respiratory passages and are swallowed. Once in the small intestine they grow into adults of both sexes. In heavy infections some of the larvae continue into the general circulation and reach various organs and tissues.

Radiologically the adult parasite appears as a longitudinal and cylindrical filling defect in the contrast-filled small bowel. They are usually found in the jejunum, but may migrate to the nasopharynx, stomach, or appendix. Large masses of worms may cause intestinal obstruction. The contrast agent may be ingested by the worms and remain visible as a fine threadlike shadow in their intestinal tract.

The diagnosis is confirmed by recovery of the parasite from the stool or sputum. The treatment today is usually with a piperazine salt, such as piperazine citrate (Antepar).

Aerotherapy

Among the hundred or more types of healing offered to the sophisticated is aerotherapy. Obviously aerotherapy means treatment by air, but in this instance hot air is particularly concerned. The patient is baked in a hot oven. Heat relieves pain and produces an increased flow of blood to the part heated. The blood aids in removing waste products and brings to the part the substances that overcome infection. There is nothing essentially wrong about hot air therapy.

Aerotherapy as one department of physical therapy becomes a cult when it is used to the exclusion of all other forms of healing. In New York a progressive quack established an institute equipped with special devices for pouring hot air over various portions of the body. He issued a beautiful brochure, illustrated with the likenesses of beautiful damsels in various states of negligee, smiling the smile of the satisfied, under his salubrious ministrations. In this document appeared incidentally the claim that hot air will cure anything from ague to zoster.*

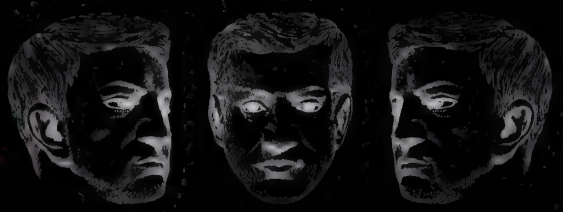
Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.

SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.



ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q.* 4 *h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA SINUTAB® FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

Tumor Conference

Esophageal Cyst

BENIGN ESOPHAGEAL lesions make up 0.5 to 2.5% of all esophageal tumors, leiomyomas being the most common. Esophageal cysts or duplications of the esophagus are considered to be rare.[11] With this in mind, we felt that the following case report of an esophageal cyst that occurred in an adult would be of interest.

Case Report

A 33-year-old white male was admitted to the Minneapolis Veterans Hospital because of an acute onset of epigastric pain that radiated around both sides and to the back. This pain had persisted for one week and was less intense following vomiting. Emesis would occur regularly, approximately fifteen minutes after meals. The patient had been examined at another hospital and given antacids, which relieved his epigastric pain.

History

Past history and systems review revealed that the patient had an active duodenal ulcer diagnosed by x-ray in 1961, which had been present by history since age 15. Diabetes mellitus had been diagnosed six years previously. At that time the patient was started on oral hypoglycemic agents but since has required 15 units NPH insulin daily. Six years ago he experienced an unexplained episode of back pain. In 1962 he swallowed an unknown amount of "stripping" acid. He did not experience vomiting or other clinical evidence of esophagitis or obstruction at that time.

Examination

Physical examination revealed a well-developed, healthy-appearing male with a blood pressure of 120/70, a regular pulse of 88, and a weight of 160 pounds.

Laboratory Studies

Laboratory findings consisted of a urinalysis that showed 1-3 wbc. with specific gravity of 1.027, albumin 0, sugar 4+, acetone slight; and a creatinine clearance 98 ml/min. Hematology—wbc. 14,000 with 75% PMNs, 17% lymphs, 8% monos, 1% eosinophils, and hemoglobin 13.3 mg%. Serology was negative. Chemistries: glucose 164, serum acetone slight, BUN 22. Gastric analysis revealed 40° total acid and 30° of free acid. Serum electrolytes were sodium 138, potassium 4.8, chloride 92, CO_2 24, calcium 10.3 and phosphorus 3.5. Prothrombin time was 13.7 seconds with a control of 12.5 seconds. BSP was 2% and alkaline phosphatase was 13.3, total protein 7.6 with an albumin of 4.1 and a globulin of 2.5. SGOT was 8. Stool guaiacs were negative.

A chest film showed a small retrocardiac density to the left of the vertebral column. An esophagram and upper gastrointestinal series showed a smooth deformity of the distal third of the esophagus. Cineradiography of the esophagus confirmed the presence of

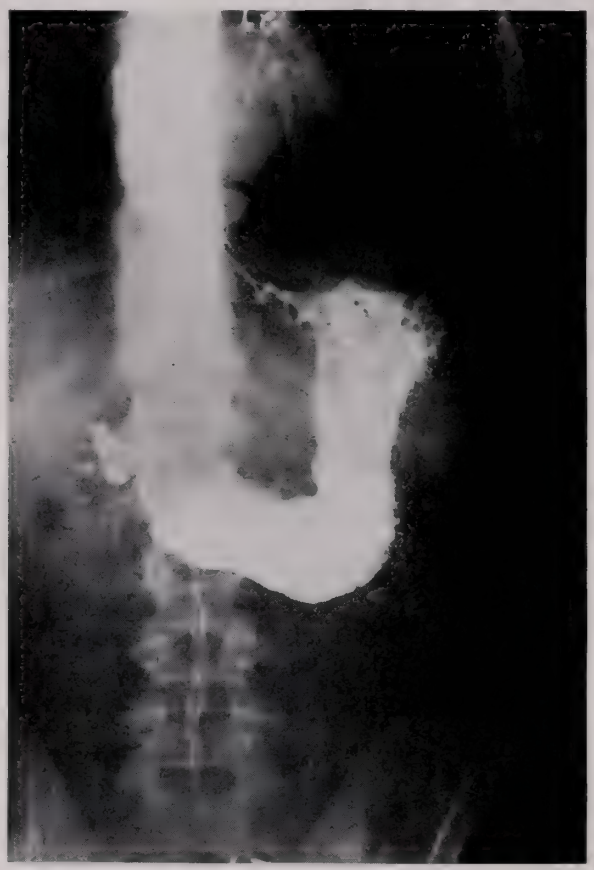

Fig. 1—Smooth deformity of the distal esophagus secondary to extraluminal compression by a retrocardiac mass. Note also the deformity of the duodenal bulb.

this deformity and showed an absence of normal peristalsis in this area.

Treatment

On March 15, 1967, the patient underwent a left thoracotomy. A cystic lesion of the lower esophagus was found, with no line of cleavage between the mass and the esophagus. The mass was opened at a point most lateral to the palpated nasogastric tube and found to be lobulated with two communicating cavities. Since no cleavage plane could be developed between the cyst and the esophagus, the mass was partially removed, leaving the common cyst-esophageal wall intact (Figure 1). The thickened mediastinum was closed loosely over the esophagus, leaving the distal part open for drainage. Microscopic examination of the specimen showed ulceration in one portion of the cyst wall. The lining of the cyst was pseudocolumnar ciliated epithelium.

The postoperative cineradiograph revealed patency of the esophagus with normal passage of barium (Figure 2). The patient has gained weight postoperatively and has no dysphagia.

Discussion

Blasius is given credit for having been the first to report a case of esophageal duplication in 1711.[12] The area of greatest controversy concerning esophageal cysts is their origin, and several investigators have written excellent reviews of the major hypotheses in that field[4,13] (Table). During

TABLE

Hypotheses Concerning the Origin of Esophageal Cysts
(Taken from M. A. Cassel[1])

1. Origin from embryonic diverticula.
2. Origin from omphalomesenteric system or Vitelline duct.
3. Failure of coalescence of the vacuoles in the transverse axis when the alimentary tube is in the solid stage.
4. Sequestration of embryonic multipotential entodermal cells from the lung bed area of the primitive alimentary analog with later growth and development.
5. Imbalance of organizational substance in embryonic life.
6. Abnormal or isolated twinning theory of origin similar to dermoid and teratomas.

its embryological development sequence, the esophagus is lined with simple columnar, pseudostratified ciliated columnar, and finally stratified squamous epithelium. Esophageal cysts may be lined by any of the above types of epithelium. Classifying the foregut cysts as acquired or congenital on the basis of the epithelial lining is difficult, since more than one type of epithelium may be present in the same cyst. An occasional report of malignancy arising in a cyst has been recorded.[3]

Grossly, esophageal cysts are spheroid and usually do not communicate with the esophagus.[8] Microscopically, the epithelium may be squamous, columnar, or pseudostratified columnar which is commonly ciliated.[2] In the less common double esophagus, the second lumen is lined by normal squamous epithelium, and the wall has normal layers except for intermingling of the outer muscular layer of the common wall.

Fig. 2—Postoperative barium swallow demonstrates essentially normal esophageal contour and passage of barium.

Esophageal cysts in adults are often asymptomatic and are commonly found in the lower half of the esophagus.[11] When symptoms occur, they are secondary to inflammation or infection, at which time they increase in size and cause pain, distortion, and malfunction of the esophagus at the level of the cyst. Patients with symptomatic esophageal cysts usually complain of one or all of the following symptoms: dysphagia, regurgitation, anorexia, weight loss, recurrent episodes of pneumonitis, dyspnea, wheezing or choking episodes.[9,10] The patient reported had dysphagia.

The diagnosis of intramural benign tumors and cysts depends on roentgenographic and endoscopic findings. On roentgenographic studies, an esophageal cyst is represented by a sharply outlined, smooth, ovoid, or lobulated filling defect in the barium-filled esophagus which forms a relatively sharp angle with the adjacent esophageal wall when seen in the lateral or anteroposterior views. On esophagoscopy, the mucosa is intact, overlying a bulging area of the esophageal lumen.[10,12] The right pleural cavity is affected more frequently than the left.[13]

Surgical excision is the treatment of choice. Most duplications of the esophagus can be enucleated without damage to the esophageal mucosa and the muscular wall of the esophagus reconstructed.[10] In the event of larger intramural cysts or duplications of esophagus (a double esophagus), division of the common wall may be required. Esophageal duplications that extend below the diaphragm have been done as a staged procedure.[7,10] Because of associated suppurative changes produced in the adjacent lung by extension of the ulceration and infection in the esophageal cyst a pulmonary resection may be indicated.[13] Excision of esophageal duplications is necessary in order to rule out malignancy.

Even though the patient is suspected of having a benign cyst, exploration is warranted because of the diagnostic uncertainty. The occurrence of complications seems frequent enough to justify operative removal of these cysts.

Conclusion

A 30-year-old diabetic, with an esophageal cyst causing dysphagia, was completely relieved by surgery.

He's had enough excitement for one day.

For the patient who has been through an accident, the worry and anxiety following the experience may actually heighten the perception of pain. This is why there's a classic 1/4 grain *sedative* dose of phenobarbital in Phenaphen with Codeine—*to take the nervous "edge" off,* so the rest of the formula can control the pain more effectively.

Phenaphen® with Codeine

Phenaphen® with Codeine No. 2, No. 3, or No. 4 contains: *Phenobarbital* (1/4 gr.), 16.2 mg. (Warning: may be habit forming); Aspirin (2 1/2 gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Hyoscyamine sulfate, 0.031 mg.; Codeine Phosphate, 1/4 gr. (No. 2), 1/2 gr. (No. 3), or 1 gr. (No. 4). (Warning: may be habit forming).

THE COMPOUND ANALGESIC THAT CALMS INSTEAD OF CAFFEINATES

Indications: Phenaphen with Codeine provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon, although nausea, constipation and drowsiness may occur. **Dosage:** 1 or 2 capsules at 2 to 4 hour intervals, or as directed by physician. For further details see product literature.

RICHMOND, VA. 23220 A·H·ROBINS

LOW-BACK PAIN

A CONSERVATIVE, FOUR-POINT PROGRAM

The low back pain that is most frequently seen in general practice is mechanical in nature, i.e., postural back pain, joint dysfunction and acute back strain.[1,2] For this type of discomfort, a conservative regimen is usually sufficient to relieve aches and pains, and to help keep the patient functioning. Components of this basic program include:

1 Bed "If the patient is in the pain-spasm-cycle...there is no alternative or substitute for absolute bed rest..."[3]

2 Board "Boards should be ordered under the mattress...these boards act by immobilizing the spine..."[4]

3 Heat "A very valuable method of applying heat at home is a prolonged hot bath..."[5]

4 Robaxin®-750 (methocarbamol, 750 mg. capsule-shaped tablets) A well-tolerated[6] skeletal muscle relaxant, methocarbamol helps relieve spasm "...without interfering with normal tone and movement."[7] And there is little likelihood of sedation.[6]

Indicated for relief of skeletal muscle spasm. **Contraindicated** in hypersensitive patients. **Side Effects** (lightheadedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently. See product literature for further details. **Also available:** Robaxin® Tablets (methocarbamol, 500 mg.) Robaxin Injectable (methocarbamol, 1 Gm./10 cc.)

Clinical Path Conference

Mycotic Aneurysms of the Left Ventricle and Ascending Aorta*

Dr. Yang Wang:**

The patient, a 36-year-old white man, had been treated in his home community for bacterial endocarditis for a period of five weeks, during which time coagulase-negative Staphylococcus aureus had been cultured repeatedly from the blood. A month after discharge from the hospital he was admitted to the University of Minnesota Hospitals because of hemoptysis, fever and chills.

Physical examination revealed a febrile, debilitated, dyspneic man. The temperature was 103°F. The blood pressure measured 110 mm. Hg. systolic and 70 mm. Hg. diastolic. There were signs of severe congestive cardiac failure. The maximum cardiac impulse was in the anterior axillary line in the seventh intercostal space and was left ventricular in type. A grade 3/6 pansystolic murmur of tricuspid incompetence was present and, in addition, an early diastolic blowing murmur was audible along the left sternal border. A diastolic gallop was detected at the apex. The pulmonic component of the second heart sound was accentuated. Examination of the lungs revealed signs of consolidation of the lower lobe of the right lung.

The concentration of hemoglobin was 9.0 Gm. per 100 ml. of blood and the total leukocyte count was 16,300 per cu. mm., of which 90 per cent were neutrophils. The erythrocyte-sedimentation rate was 72 mm. per hour (Westergren). The value for blood urea nitrogen was 29 mg. per 100 ml. of blood. Blood cultures were sterile.

The clinical diagnosis was aortic insufficiency, perhaps secondary to perforation of an aortic cusp, with recurrent bacterial endocarditis. Treatment with penicillin, digitalis and diuretics was instituted. Death occurred suddenly five days after admission.

Dr. Elliot Chesler:†

On the patient's admission the electrocardiogram showed first degree A-V block (P-R interval 0.26 sec.) and intraventricular conduction delay of the left bundle branch type. In addition, the sum of the R wave in V_6 and the S wave in V_1 was 51 mm.; this suggested left ventricular hypertrophy. Subsequently the first degree A-V block persisted and left bundle branch block became established (QRS = 0.12 sec.) (Figure 1).

**Associate Professor, Department of Medicine, University of Minnesota, Minneapolis, Minnesota.

†Physician, Cardiac Clinic, Baragwanath Hospital and University of the Witwatersrand, Johannesburg, South Africa, on leave of absence; currently, Research Associate in Cardiovascular Pathology, The Charles T. Miller Hospital, St. Paul, Minnesota; Instructor, Department of Medicine, University of Minnesota, Minneapolis, Minnesota.

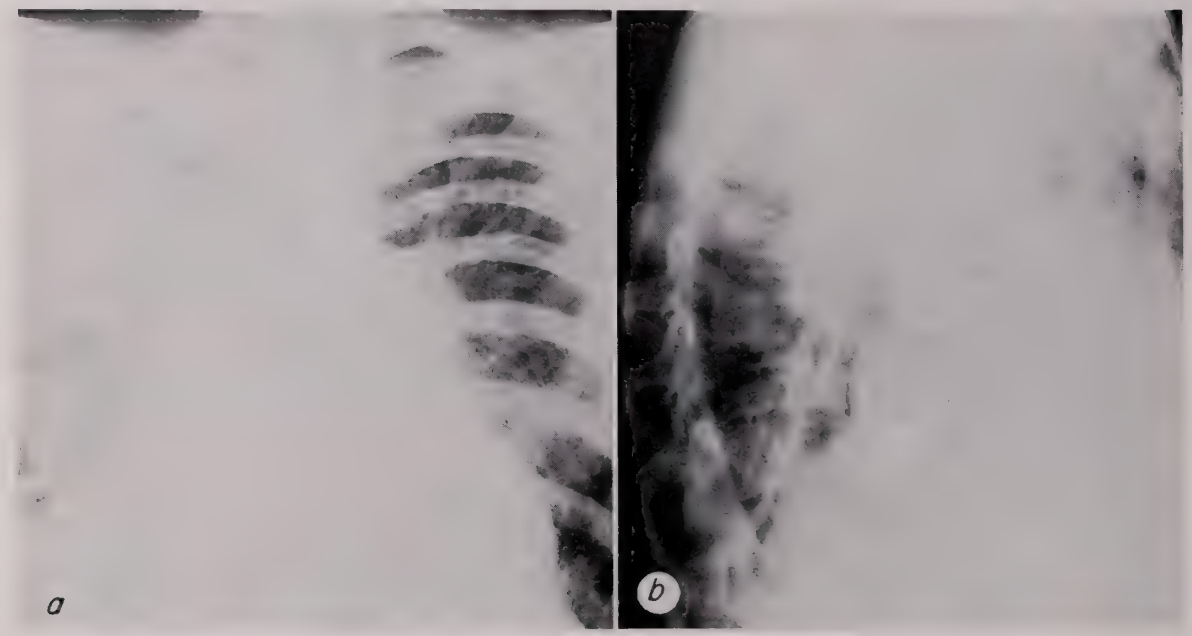

Fig. 1—Roentgenograms of thorax. (a) Posteroanterior and (b) left lateral views.

The thoracic roentgenograms showed left ventricular enlargement and prominence of the ascending aorta and aortic knuckle. Multiple infiltrates, consistent with infarcts, were present in the right pulmonary field (Figure 2).

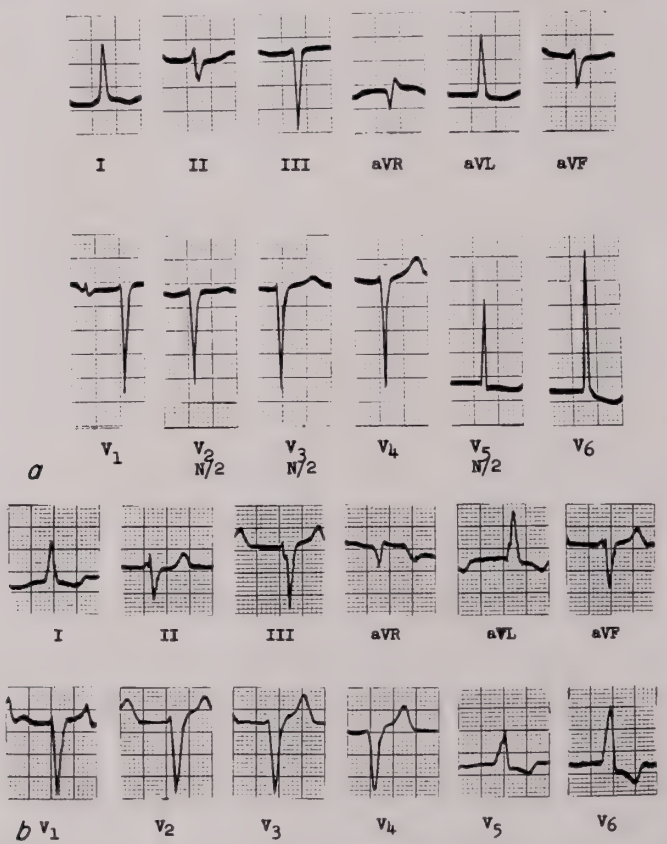

Fig. 2—Electrocardiograms. (a) On admission and (b) three days after admission.

The clinical, radiologic and electrocardiographic features were thus compatible with severe aortic insufficiency. The heart failure was almost certainly precipitated by bacterial endocarditis and aggravated by the occurrence of pulmonary embolism.

The abnormalities noted in the electrocardiogram are of considerable interest. While prolongation of the P-R interval is a not uncommon finding in cases of aortic insufficiency, left bundle branch block is unusual. This combination of abnormalities in conduction suggests a lesion involving the conduction system and may be observed in circumstances unrelated to bacterial endocarditis. This is rheumatoid aortitis and aortic regurgitation with granulomatous involvement of the conduction tissue.[1] There was no evidence of rheumatoid arthritis in our patient. It is tempting to postulate, therefore, that the aortic insufficiency was a result either of a congenital bicuspid aortic valve or rheumatic endocarditis, and that bacterial infection of the valve had resulted in septic emboli to the conduction system.

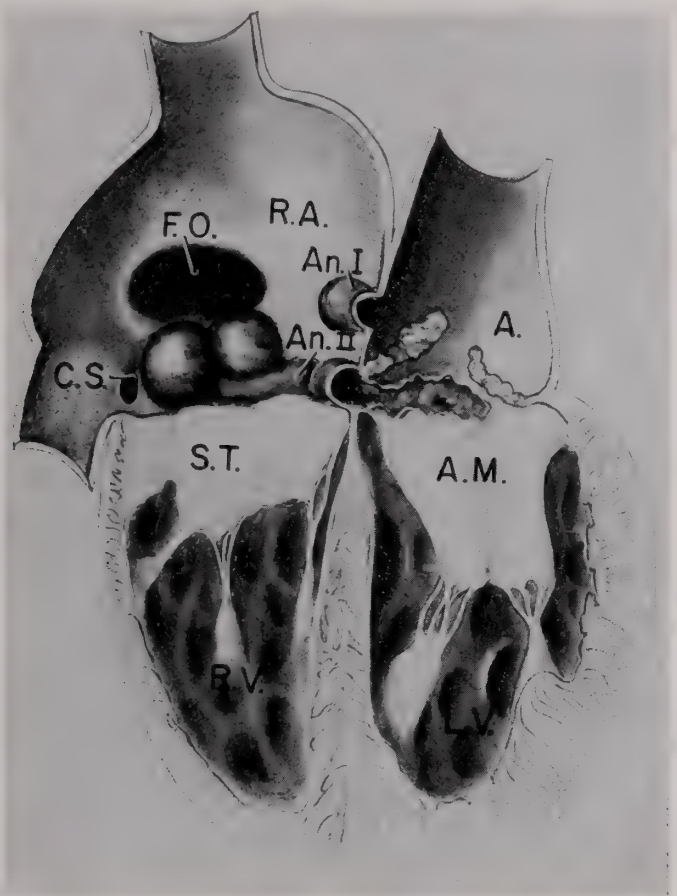

Fig. 3—Drawing representing frontal section of heart revealing interior of right atrium (R.A.), ascending aorta (A.) and right (R.V.) and left (L.V.) ventricles. Above vegetations on partially destroyed aortic valve is a small mycotic aneurysm (An.I) of the ascending aorta. Beneath the aortic valve and at the membranous septum is the mouth of a larger mycotic aneurysm (An.II). The latter extends into the atrial septum to appear as a lobulated structure anterior to the ostium of the coronary sinus (C.S.) and inferior to the fossa ovalis (F.O.). S.T. = septal leaflet of tricuspid valve; A.M. = anterior leaflet of mitral valve.

In dealing with bacterial endocarditis one realizes that renal involvement is not uncommon and in some cases dominates the clinical picture. The level of blood urea was slightly elevated in this patient, suggesting that an element of renal involvement may have been present.

Pathologic Findings

Dr. Michael Korns:*

The heart was enlarged, weighing 700 grams. The increase in weight was mainly on the basis of extreme left ventricular hypertrophy. The focal point of interest was bacterial endocarditis involving a congenital bicuspid aortic valve (Figure 3). Extension of infection from this site resulted in several secondary lesions, two of which were mycotic aneurysms. The smaller of these involved the ascending aorta, and the other involved the membranous portion of the ventricular septum. Both aneurysms extended into the atrial septum.

The aortic valve was composed of two cusps, an anterior and a posterior. A shallow raphe extended from the aortic wall onto the aortic side of the anterior and larger cusp. The active bacterial endocarditis of the aortic valve was represented by a major defect in the posterior cusp, only the commissural aspects of the cusp remaining. Friable vegetations were deposited upon the edges of the defect in the cusp (Figure 4*a*). From the posterior cusp,

*Senior Research Associate in Cardiovascular Pathology, The Charles T. Miller Hospital, St. Paul, Minnesota; Clinical Instructor in Pathology, University of Minnesota, Minneapolis, Minnesota.

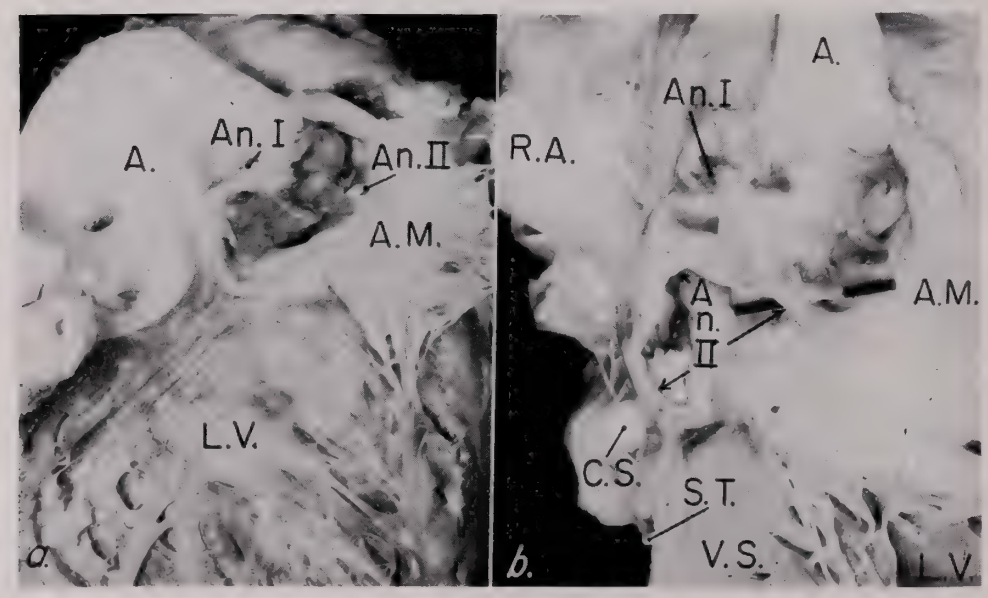

Fig. 4—(a) Ascending aorta (A.), congenital bicuspid aortic valve, and left ventricle (L.V.). At the junction of the anterior leaflet of the mitral valve (A.M.) and the posterior leaflet of the aortic valve the probe is in the ostium of the larger mycotic aneurysm (An.II) which involves the membranous ventricular septum. The ostium of the smaller mycotic aneurysm (An.I), which involves the ascending aorta, is obscured by vegetations covering the nearby aortic cusp. (b) Base of heart in plane of section similar to that in Figure 3 revealing right atrium (R.A.), ascending aorta (A.), aortic valve, and ventricular septum (V.S.). Black probe passes behind remnant of aortic valvular cusp into larger mycotic aneurysm (An.II) which extends to the level of the coronary sinus (C.S.) and encroaches upon the wall of the right atrium (R.A.). A tiny segment of septal leaflet of tricuspid valve (S.T.) is visible beneath the coronary sinus. Smaller mycotic aneurysm (An.I) begins in aorta and also encroaches upon right atrium.

vegetations extended inferiorly to involve the subjacent membranous septum and the base of the anterior mitral leaflet.

A perforation in the membranous septum led into a lobulated aneurysm which lay in the atrial septum and extended to the posterior wall of the right atrium (Figure 4*b*). The aneurysm in the atrial septum measured about 4 x 2 cm., and its two locules bulged into the right atrial cavity (Figure 5).

Fig. 5—Right atrium (R.A.) and right ventricle (R.V.). Two loculi of larger mycotic aneurysm (An.II) bulge against the septal wall of the right atrium between the fossa ovalis (F.O.) and septal leaflet of tricuspid valve (S.T.). Probe is in coronary sinus (C.S.), the ostium of which lies just posterior to the aneurysm.

The most posterior aspect of the aneurysm encroached on, and slightly compressed, the ostium of the coronary sinus. The aneurysm encroached on but did not involve the atrioventricular node (Figure 6).

In addition, a separate aneurysm involved the posterior wall of the ascending aorta. The mouth of the aortic aneurysm measured about 8 mm. in diameter, and its body measured about 1 cm. in greatest dimension. This also presented against the septal wall of the right atrium. The aneurysm of the aorta and that of the membranous septum, although near each other in the atrial septum, did not communicate, nor did the cavity of either aneurysm communicate with the right atrial cavity (Figure 3).

Histologic examination revealed a destructive process involving the aortic valve. Vegetations deposited upon the surface of the valve were incompletely organized and contained bacterial colonies. In each aneurysm the lining was formed by granulation tissue which lay on a layer of dense fibrous tissue (Figure 7). Secondary lesions in the immediate vicinity of the aortic valve included a 1-mm. perforation in the anterior leaflet of the mitral valve. Numerous myocardial infarcts of varying age were found in all portions of the left ventricle.

An incidental finding was a defect in the muscular part of the ventricular septum, 2 mm. in diameter, closed by a fibrous membrane. This was regarded as a spontaneously closed muscular ventricular septal defect. Intrinsically, the tricuspid valve was normal.

The lungs showed chronic congestion, organizing pneumonitis, patchy bronchopneumonia and hemorrhage; and some of the vessels, both arteries and veins, contained thrombi. In addition to the pulmonary congestion, other manifestations of congestive cardiac failure included minimal bilateral pleural effusions and generalized visceral congestion. With respect to the latter, there was widespread centrolobular hepatic necrosis.

Evidence of systemic embolism was the presence of a gross infarct in one kidney and a microinfarct of the pituitary gland.

Summary

Dr. Jesse Edwards:*

Of interest are several features in this case, such as (1) the recrudescence of infection, (2) the congenital bicuspid nature of the aortic valve, (3) the presence of multiple infarcts in the myocardium and (4) the secondary mycotic aneurysms.

Recurrent Infection

When a patient with bacterial endocarditis suffers a recurrence and two

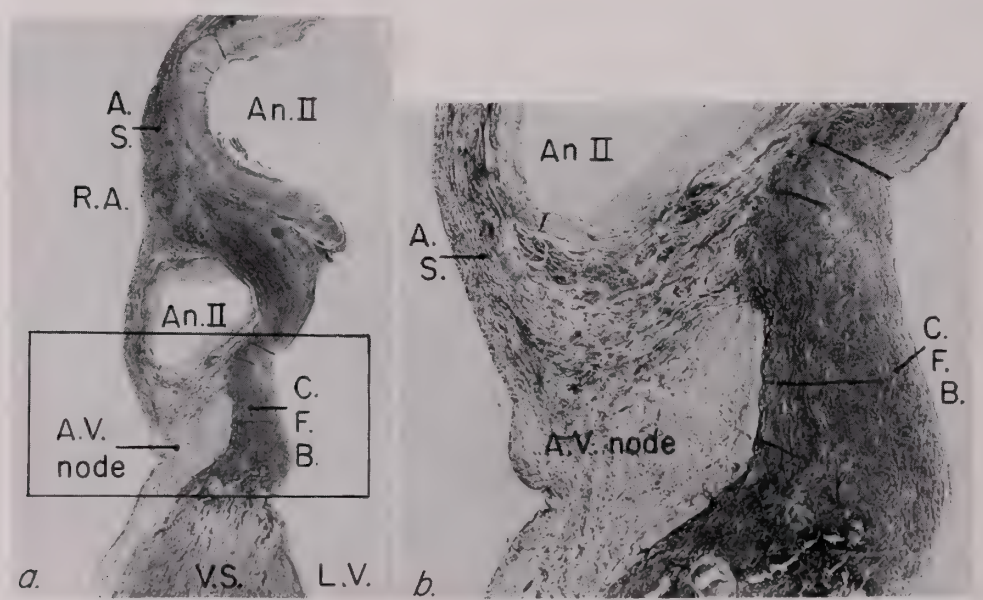

Fig. 6—(a) Photomicrograph of frontal section through base of ventricular septum (V.S.) and adjacent atrial septum (A.S.). Two locules of larger aneurysm (An.II) abut on septal wall of right atrium (R.A.). The lower locule of the aneurysm approaches but does not invade the atrioventricular node which lies in the concavity of the central fibrous body (C.F.B.). Elastic tissue stain; X4. (b) Photomicrograph of that part of *a* enclosed in rectangle. Elastic tissue stain; X14.

separate organisms are involved, it is a simple matter to conclude that reinfection had occurred. When the same organism is obtained in two episodes, such an explanation may be the correct one. Yet one cannot rule out a situation of continuous infection during which the clinical picture suggested arrest of the initial infection. In the case discussed blood cultures positive for Staphylococcus aureus were obtained initially and then cultures yielded no growth. Cultures of the blood yielded negative results during the second admission. The nature of the aortic valvular lesions was such as to indicate that an active infectious process was present at the time of death. It is probable that the original infection had not been completely overcome and that for some reason cultures of the blood yielded no growth even though infection was still active.

One cannot, however, entirely exclude the possibility that the organism observed in the aortic valve was dead and therefore that the infection had been overcome, leaving the patient with a serious mechanical problem in the form of aortic insufficiency.

Bicuspid Aortic Valve

It will be recalled that the aortic valve was congenitally bicuspid. This is a

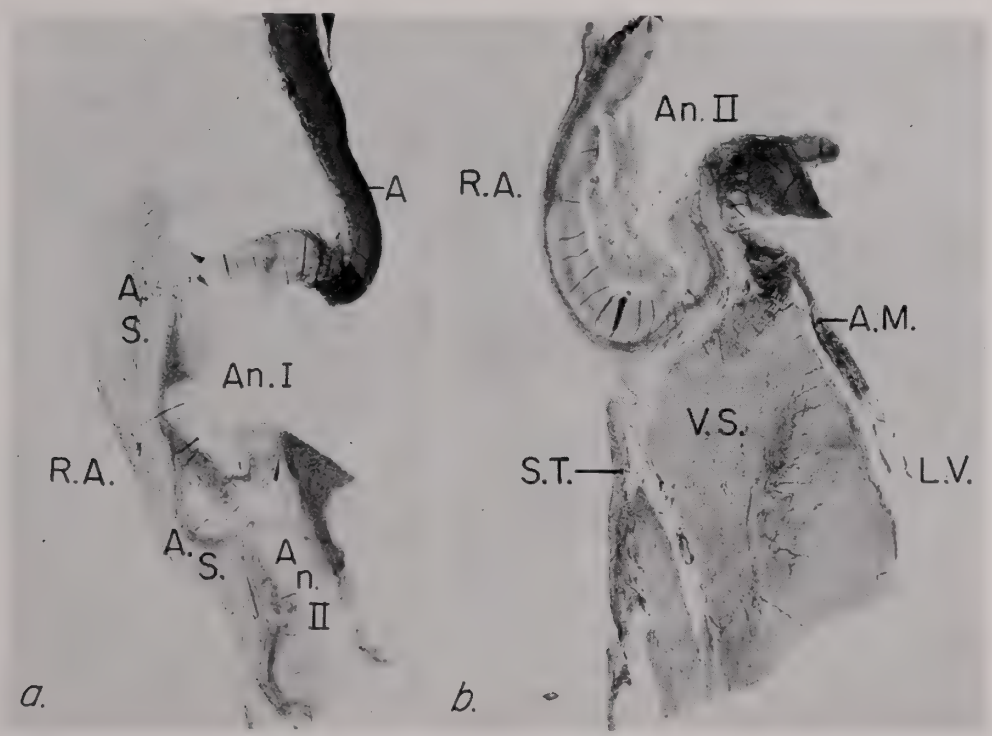

Fig. 7—Low-power photomicrographs of frontal section through aorta and ventricular septum to reveal the ostium of each of the mycotic aneurysms. (a) Extending through the wall of the ascending aorta (A.) is the mouth (An.I) of the smaller aneurysm. The fundus of the latter abuts on the septal wall (A.S.) of the right atrium (R.A.). A small part of the upper portion of the larger aneurysm (An.II) is also shown. Elastic tissue stain; X3. (b) Atrial septum and ventricular septum (V.S.). Larger mycotic aneurysm (An.II) containing exudate abuts on the septal wall of the right atrium (R.A.) above the septal leaflet of the tricuspid valve (S.T.). A.M. = anterior leaflet of mitral valve. Elastic tissue stain; X3.

common predisposing anatomic state for aortic valvular bacterial endocarditis. While many aortic valves that become infected are bicuspid in nature, of these about half are so on the basis of a congenital anomaly of the aortic valve. In the remaining half the basis for this process is antecedent rheumatic fever.

It was clear clinically that the patient was suffering from aortic valvular insufficiency. Pathologically, the destructive nature of the valve would amply explain this valvular disturbance; yet one recognizes that a congenital biscuspid valve may be incompetent without infection. Did this patient have an incompetent congenital bicuspid valve in which the degree of incompetence was accentuated by the destructive effects of the bacterial endocarditis?

The fact that the heart weighed 700 grams would suggest that aortic insufficiency had been present for more than two months, the period during which bacterial endocarditis was evident.

Multiple Infarcts

The multiple infarcts observed in the myocardium are representative of a common occurrence in bacterial endocarditis involving the left side of the heart.[2] Such lesions are to be interpreted as the result of embolism of infective material from the involved valve into the coronary arterial system. While such emboli were not described by Dr. Korns, one must assume that serial sections, including vessels supplying infarcted areas in the myocardium, would reveal such embolic lesions.

Mycotic Aneurysms

Mycotic aneurysms in relation to the aortic valve are more common in instances of aortic bacterial endocarditis than in comparable disease of the mitral valve for two reasons: (1) infective material attached to cusps of the aortic valve may make direct contact with the aortic wall and serve to inoculate areas of such contact with the infecting organism; and (2) the concentration of bacteria is greatest in relation to the valve that is infected.

In relation to the aortic valve, common sites for mycotic aneurysms are the aorta, either at a sinus or in the ascending portion, and the anterior leaflet of the mitral valve. Two such lesions were found in addition to an aneurysm of the ventricular septum. The lesion of the mitral valve had caused a small perforation and had undoubtedly been responsible for mitral insufficiency. This must have been of minor degree, as the perforation in the anterior mitral leaflet was small. The aneurysm of the aorta had not perforated. If it had, one must conclude from its position that it would have led to an aortic-right atrial communication.

The aneurysm of the ventricular septum is of special interest. In the first place such a mycotic aneurysm so extensive as to extend to the posterior aspect of the right atrium is rare. Had this aneurysm perforated, a left ventricular right atrial communication would have resulted. The question may be raised as to the relationship of the aneurysm in the ventricular septum to the observed disturbances in atrioventricular conduction.

The aneurysm was observed to encroach upon but not to involve the atrioventricular node. This would suggest a positive relationship between the anatomic observation and the disturbance in conduction. The conduction tissue is sensitive to mechanical pressures. It is, therefore, possible that increased tissue pressure around the aneurysm may have affected a func-

tional disturbance of the atrioventricular node. Another explanation is that edema of tissues around the focal point of infection may have involved the node to such a degree as to make it malfunctional.

Diagnosis

Mycotic aneurysms of the left ventricle and ascending aorta, complicating aortic valvular bacterial endocarditis.

On Wine in Acute Diseases

One must determine when sweet, strong, and dark wine should be given in acute diseases. Wherefore the sweet affects the head less than the strong, attacks the brain less, evacuates the bowels more than the other, but induces swelling of the spleen and liver; it does not agree with bilious persons, for it causes them to thirst; it creates flatulence in the upper part of the intestinal canal, but does not disagree with the lower part, as far as regards flatulence; and yet flatulence engendered by sweet wine is not of a transient nature, but rests for a long time in the hypochondria. And therefore it in general is less diuretic than wine which is strong and thin; but sweet wine is more expectorant than the other. But when it creates thirst, it is less expectorant in such cases than the other wine, but if it do not create thirst, it promotes expectoration better than the other. The good and bad effects of a white, strong wine have been already frequently and fully stated in the disquisition on sweet wine; it is determined to the bladder more than the other, is diuretic and laxative, and should be very useful in such complaints; for if in other respects it be less suitable than the other, the clearing out of the bladder effected by it is beneficial to the patient, if properly administered. There are excellent examples of the beneficial and injurious effects of wine, all which were left undetermined by my predecessors. In these diseases you may use a yellow wine, and a dark austere wine for the following purposes: if there be no heaviness of the head, nor delirium, nor stoppage of the expectoration, nor retention of the urine, and if the alvine discharges be more loose and like scrapings than usual, in such cases a change from a white wine to such as I have mentioned, might be very proper. It deserves further to be known, that it will prove less injurious to all the parts above, and to the bladder, if it be of a more watery nature, but that the stronger it is, it will be the more beneficial to the bowels.—*Hippocrates*

"Upper respiratory infection! I thought everything was a 'virus' these days?"

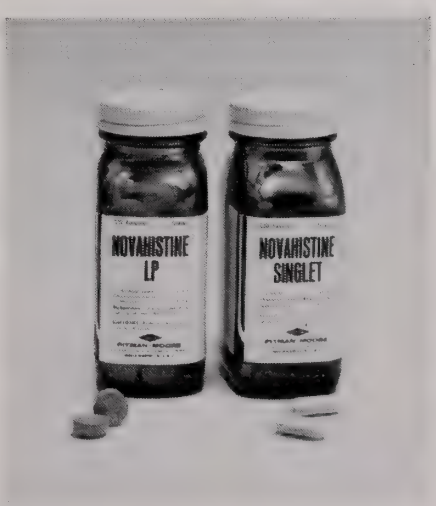
Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® in two different tablet formulations.

And let you control the dosage.

With Novahistine LP tablets and Novahistine Singlet™ tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.

Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever.



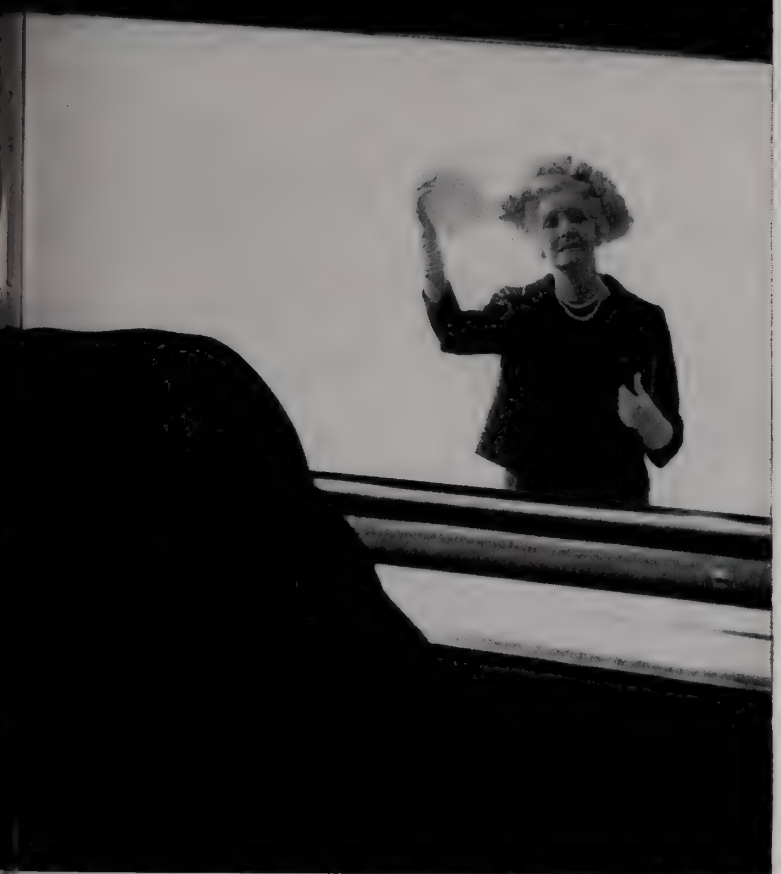
Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.

Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.

Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.



DOW PITMAN-MOORE DIVISION OF THE DOW CHEMICAL COMPANY, INDIANAPOLIS

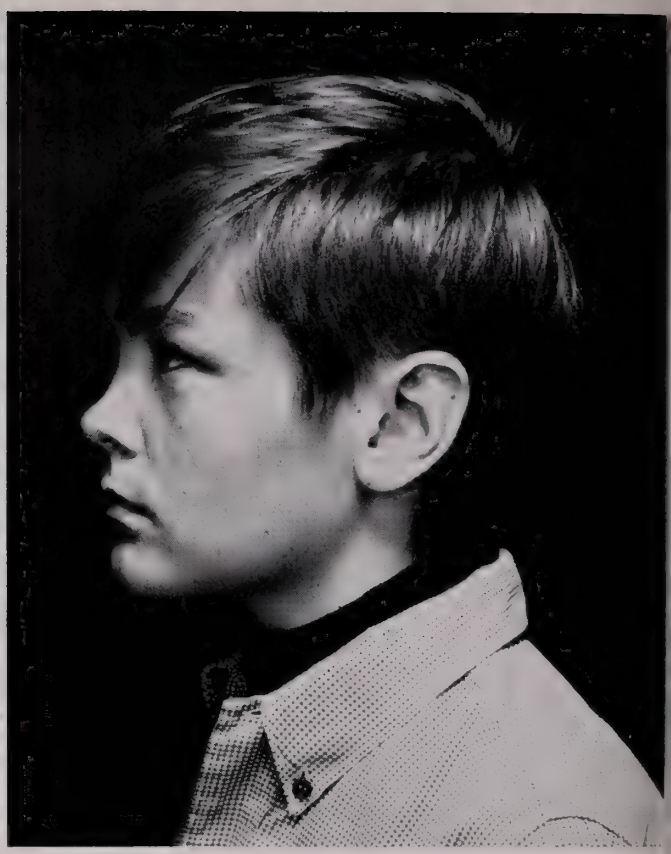
Indications: Tofrānil is recommended for the treatment of depressive states of diverse psychopathology.
Contraindications: The concomitant use of Tofrānil and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 7 days after M.A.O.I. therapy has been discontinued should be allowed before Tofrānil may be substituted. Initial Tofrānil dosage should be low, increases should be gradual, and the patient's progress should be carefully observed.
Warning: Clinical reports have suggested that there may be a risk of teratogenesis associated with the use of this compound during the first trimester of pregnancy. Unless, in the opinion of the prescribing physician, the potential benefits outweigh the possible risks, Tofrānil should not be used during the first trimester of pregnancy.
Cardiovascular complications, including myocardial infarction and arrhythmias, have occasionally occurred in susceptible individuals. Patients with cardiovascular disease should be given the drug only under careful observation and in low dosage.
Precautions: Since suicide is always a possibility in severely depressed patients and one which may persist until significant remission occurs, such patients should be carefully supervised during early treatment with Tofrānil. Some severely depressed patients may also require hospitalization and/or concomitant electroconvulsive therapy.
Because of its anticholinergic effect, caution should be observed in prescribing Tofrānil for patients with increased intraocular pressure.
In rare instances, transient cardiac arrhythmias have occurred in hyperthyroid patients and in patients receiving thyroid medication when Tofrānil was added to the regimen.
Imipramine may block the pharmacologic activity of guanethidine and other related adrenergic neuron-blocking agents.
The drug is not recommended at the present time in patients under 12 yea of age.
Adverse Reactions: Dryness of the mouth, tachycardia, constipation, dis turbances of accommodation, sweating, dizziness, weight gain, urinary frequency or retention, nausea and vomiting, peripheral neuritis, mild parkinson-like syndrome, tremors, rare cases of falling in elderly patients, confusional states (with such symptoms as hallucinations and disorientation), activation of psychosis schizophrenics and agitation (includ

When a milestone in life is marred by depression...

Often in the mind of the lonely, widowed, depression-prone individual, she's not gaining a daughter...she's losing a son. The occasion may be marred by such symptoms of depression as feelings of sadness, incapacity, helplessness and hopelessness.

In about 3 out of 4 cases, Tofrānil relieves symptoms of primary depression.

As maintenance therapy in primary depressive illness, it helps prevent relapse.



Although toxic reactions severe enough to require discontinuation of Tofrānil are uncommon, in patients with cardiovascular disease, thyroid disorders, increased intraocular pressure, or in those receiving anticholinergics (including antiparkinsonism agents), the special precautions listed in the Prescribing Information should be carefully observed. The use of Tofrānil in patients receiving M.A.O.I.'s is contraindicated.

Tofrānil® imipramine hydrochloride
Geigy

ng hypomanic and manic episodes) which may require dosage reduction and/or addition of a tranquilizer or temporary discontinuation of the drug, epileptiform seizures, orthostatic hypotension and substantial blood pressure fall in hypertensive patients, purpura, transient jaundice, bone marrow depression including agranulocytosis, sensitization and skin rash including photosensitization, eosinophilia, and mild withdrawal symptoms on sudden discontinuation after prolonged treatment with high doses. Occasional hormonal effects (impotence, decreased libido, and estrogenic effects) may be observed. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those using anticholinergic agents (including antiparkinsonism drugs).
Outpatient Adult Dosage: Initially, 75 mg. daily, increased, if necessary, to 150 or 200 mg. Maintenance dosage may be lower, 50 to 150 mg. daily, if possible.
Geriatric and Adolescent Dosage: Initially, 30 or 40 mg. daily, which may be increased according to response and tolerance. It is usually unnecessary to exceed 100 mg. daily.
A lag in therapeutic response, lasting from a few days to a few weeks, should be expected. When dosage recommendations are already being followed, increasing the dosage does not normally shorten this latency period and may increase the incidence of adverse reactions.
Availability: Tofrānil: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.
(B)46-850-C

How to turn a 14-year-old boy into a hardened criminal.

Just forget your keys in your car one day.

Tempt some fourteen-year-old boy into going for a joyride.

Oh, he could be a good kid — just weak.

And taking your car might be the first time he's ever broken the law.

But the minute he hops behind that wheel and turns the key, his life may be ruined.

He'll drive around for a few hours, endangering the life of every man, woman and child who crosses his path.

He might be caught the very first time he takes a car. Or if he's not caught by the police he'll leave your car somewhere and decide to do it again, and again, until the day he does get caught.

Teen-agers steal more than 1,000 cars every day.

The U. S. Department of Justice and your state and local law-enforcement agencies are concerned.

They know that taking a car for a joyride is just the first step.

Our prisons are filled with men who started out this way. They went on to become thieves, muggers, and even killers.

You can do something to help solve this terrible problem.

Whenever you get out of your car, even for a second, take your keys. Lock your car.

Every time you do this you may keep a good boy from going bad.

ADVERTISING COUNCIL

Don't help a good boy go bad. Lock your car. Take your keys.

Dermatology

Shoe Dermatitis

A 30-YEAR-OLD woman had an eruption involving the dorsal aspects of both feet. The dermatitis was well demarcated in a band-like pattern (Figure). The onset of the eruption was traced to a recently purchased pair of sandals. A patch test with 0.25% potassium dichromate (aq. sol.) was positive.

Eruptions which involve the feet may be acute or chronic and can be incapacitating. Many skin diseases manifest themselves on the extremities, the feet in particular. Such conditions as dyshidrotic eczema (neurodermatitis), dermatomycosis, psoriasis, pyoderma, and contact dermatitis are among the more common. Of these diseases, contact dermatitis from shoes is of interest in that it may be very recalcitrant; yet the patient can be helped promptly if the diagnosis is made.

Figure

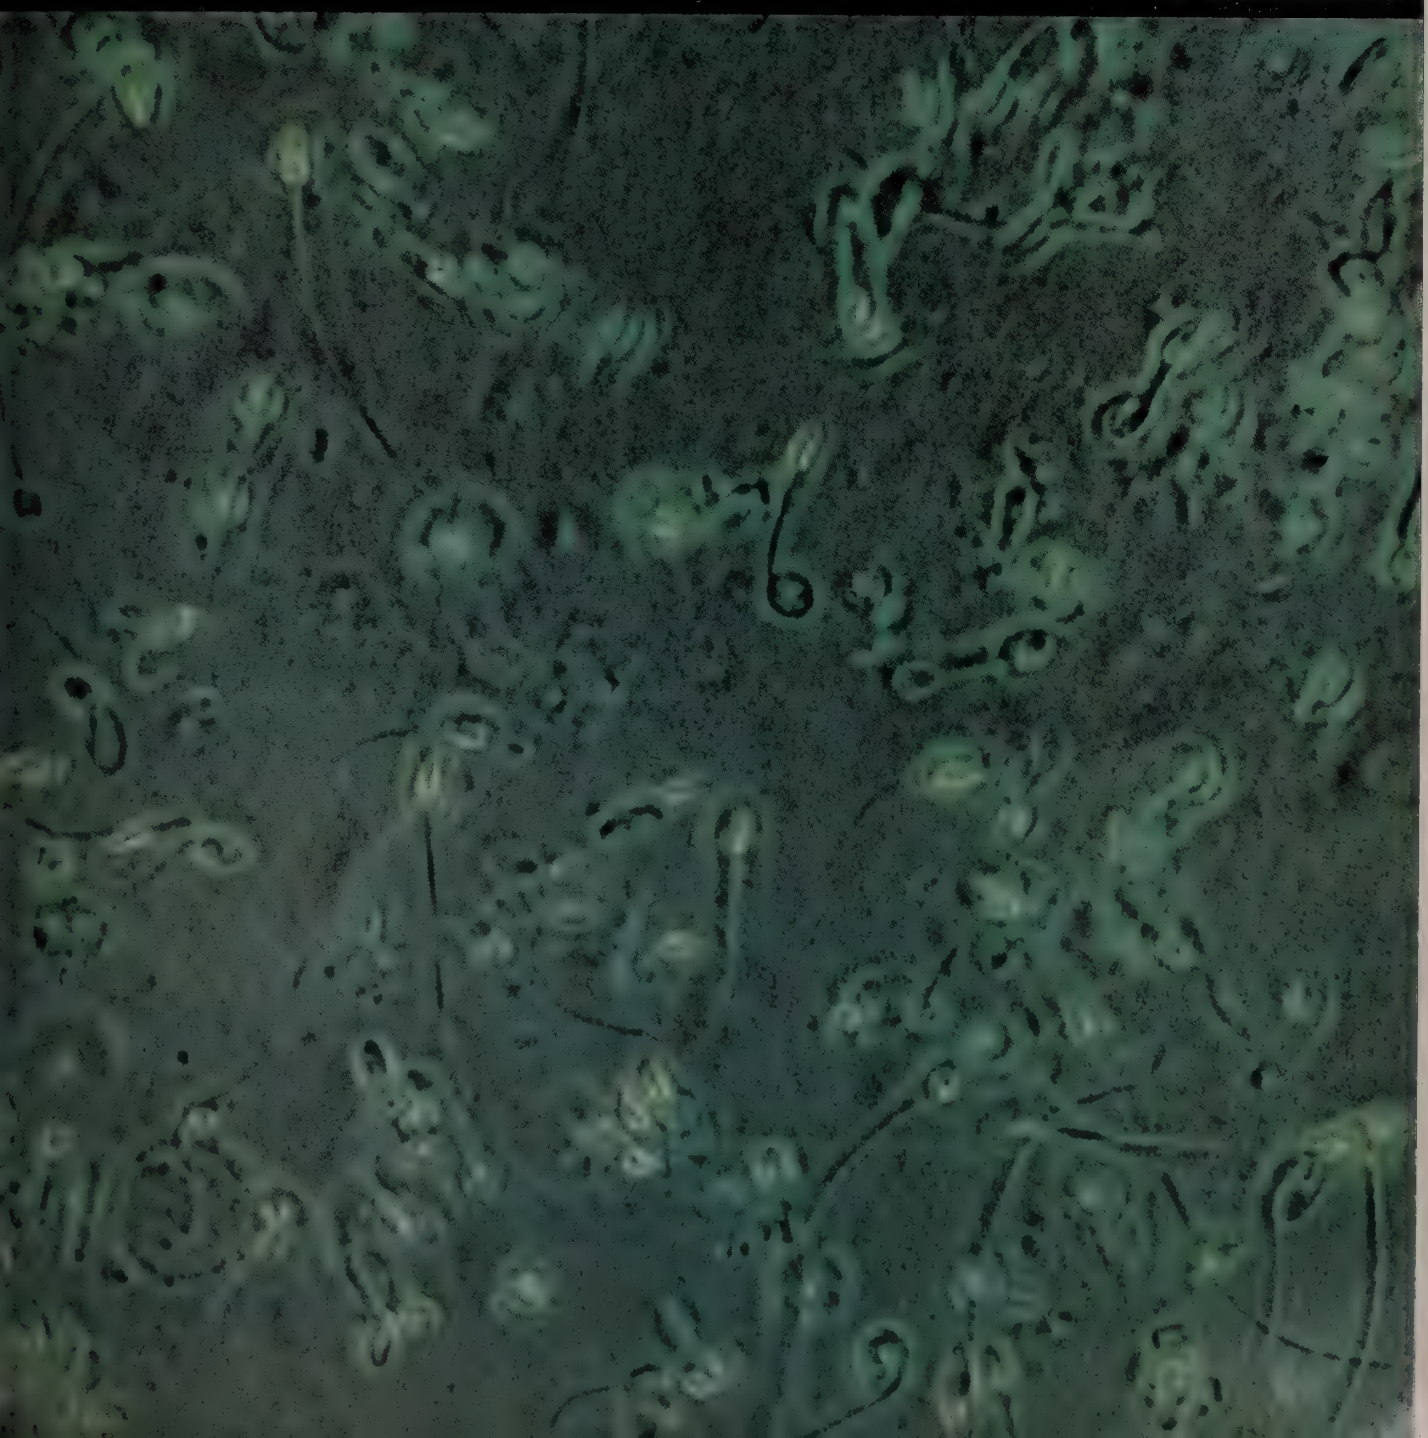
In making this diagnosis a careful history of the eruption is important, especially the initial site and character of involvement. For example, there have recently been several reports of sandal-strap dermatitis (buffalo hide). This eruption initially shows a strap-like pattern which can aid the clinician in his diagnosis (Figure). The site of onset and the pattern may also be helpful in relating the eruption with the resins, adhesives, and fabrics used as lining material in shoe construction; often multiple materials are used in the construction of a shoe.

Shoe dermatitis may be acute or chronic. It frequently begins on the dorsal aspects of the feet, especially the first toes. With time, the eruption may spread to the other toes, as well as to the dorsal foot and ankle. As a rule, unless severe, the soles and interdigital spaces are not affected, a fact which helps differentiate this condition from a mycotic infection. If the eruption is untreated and becomes acute, it may generalize. In such a situation the hands may develop an "Id"-like eruption which may be vesicular or papular and scaling, to some extent resembling the original dermatitis on the feet.

In shoes there are several components to which an individual may develop a contact allergy, such as rubber accelerators and antioxidants, tannins, dyes, and various synthetic resins. One of the most common causes of shoe dermatitis is the rubber box toe, which accounts for the fact that many of these eruptions begin on the first toe. In the rubber box toe, the rubber accelerators and antioxidants are the usual sensitizers. Monobenzylether of hydroquinone is a common antioxidant offender, while mercaptobenzothiazole and tetramethylthiuram monosulfide are accelerators which are commonly implicated. These substances may also be present in rubber adhesives used in shoes. Of the tannins, chromes and aldehydes may both cause a sensitivity. It should be noted that not all individuals who are allergic to chrome will develop a dermatitis with chrome-tanned leather, for perspiration must be present to remove the chrome from the leather. Another cause of shoe dermatitis are the various dyes, usually after the patient has re-dyed his own shoes, especially the fabric-topped varieties. Dermatitis to the dye of leather shoes is rare, for the dyes used today are quite fast.

Following recognition of this condition, primary treatment consists of controlling the acute phase of the eruption, perhaps by wet compresses, alternated with mild topical steroid ointments. Even if fungal in nature, eruptions of the feet, should not be treated initially with strong ointments (fungicides), for these often exacerbate the condition. If bacterial infection is present, systemic and topical antibiotics may be employed. When the eruption is chronic, hydrocortisone ointments are of value.

An important aspect in the treatment of this condition is the control of perspiration, which can bring into solution such chemicals as the chromes and dyes to produce sensitivity. Control or reduction of perspiration may be achieved by the use of absorbent stockings and various dusting powders. The patient should also be instructed to purchase shoes which are free of the particular factors to which he has shown a sensitivity.



Willard C. Peterson, Jr., M.D.
Minneapolis, Minnesota

Against diseases known, the strongest fence is the defensive virtue, abstinence.
—Benjamin Franklin

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl®-1.

(norethindrone 1mg. c mestranol 0.05mg.)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of NORINYL-1 (norethindrone 1 mg. with mestranol 0.05 mg.) in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with NORINYL-1. Therefore, if such tests are abnormal in a patient taking NORINYL-1 it is recommended that they be repeated after the drug has been withdrawn for two months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibromyomata may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. 5. NORINYL-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, and as in all cases of irregular bleeding *per vaginam*, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged NORINYL-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving NORINYL-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. 11. Because of the effects of estrogens on epiphyseal closure, NORINYL-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with NORINYL-1 may mask the onset of the climacteric. 13. The pathologist should be advised of NORINYL-1 therapy when relevant specimens are submitted.

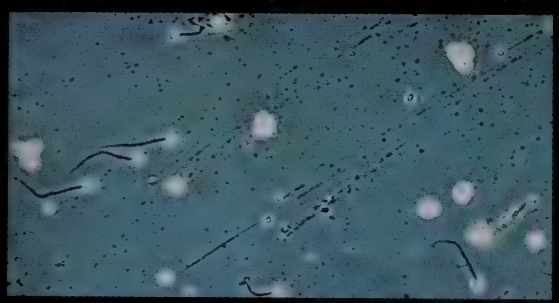
Side effects observed in patients receiving oral contraceptives: The following adverse reactions have been observed in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weigh (increase or decrease), changes in cervical erosion and cervical secretion suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression.

Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation post-treatment, premenstrual-like syndrome, change in libido, changes in appetite, cystitis like syndrome, headache, nervousnes dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodo sum, hemorrhagic eruption, itching.

The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has been neither established nor disproved): thrombophlebitis, pulmonary embolism, neuro-ocular lesions.

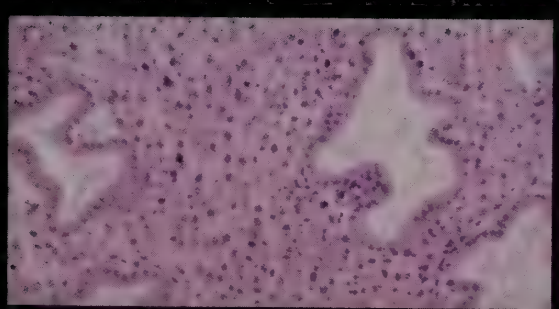
The following laboratory results may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, Factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from
SYNTEX
LABORATORIES INC., PALO ALTO, CALIF.



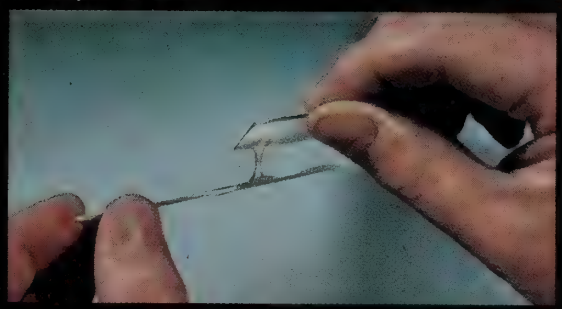
Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation. These effects are illustrated below.

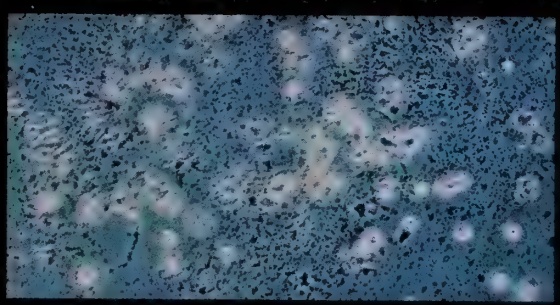


Untreated Patient

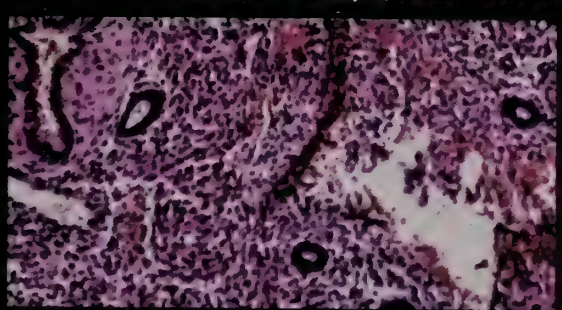
Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.



Spermatozoa appear healthy, active, freemoving.



Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.



Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.

Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl®-1 tablets
(norethindrone 1mg. & mestranol 0.05mg.)

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

Night Leg Cramps . . . Unwelcome Bedfellow

In Diabetes[1], Arthritis[2], and Peripheral Vascular Disorders[2]

now . . . specific therapy for night leg cramps

Walker

QUINAMM™

Consistently effective, QUINAMM provided complete relief in 94% of 200 patients studied, many of whom were severe cases refractory to other medication.[3] Your prescription for one tablet at bedtime often controls painful night cramps with the initial dose . . . helps restore restful sleep.

THE NATIONAL DRUG COMPANY
DIVISION OF RICHARDSON-MERRELL INC
PHILADELPHIA, PENNSYLVANIA 19144

Prescribing Information: Composition: Each white, beveled, compressed tablet contains: Quinine Sulfate 260 mg. and Aminophylline 195 mg. **Contraindication:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Grand Rounds

Pulmonary Embolism*

DAVID G. CONNOR, M.D.
Medical Resident

"It is of use from time to time to take stock, so to speak, of our knowledge of a particular disease, to see exactly where we stand in regard to it, to inquire what conclusions the accumulated facts seem to point to, and to ascertain in what direction we may look for fruitful investigations in the future."

Sir William Osler[1]

PULMONARY EMBOLISM is both a common disease and an uncommonly proven diagnosis. We should be concerned with this disease because it is preventable, it is treatable, it is reversible, and because most cases of fatal pulmonary embolism occur on the general medical service. We should define and emphasize clinical aspects of the disease because most often the diagnosis is made primarily by suspecting the disorder and only secondarily by the various laboratory measures available for confirmation. We should be eager to gain knowledge about pulmonary embolism because the phenomenon is so often integrated with the course of other disease states. Lastly, we should fear the disease because of the very nature of our anatomy; the lungs serve as a nonrenewable filter catching all manner of particulate matter, and we are all subject to pulmonary embolism.

I should like to emphasize the diagnosis of pulmonary thrombo-embolism, touching only briefly on pathogenesis and treatment. I will begin with a case report.

Case Report

A 39-year-old negro mother of seven had been well until the age of 22, when she developed symptoms and signs of rheumatoid arthritis. The disorder was severe and she was treated for nine years with various combinations of corticosteroid preparations

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, October 2, 1967.

with good results; but she developed a severe weakness, with wasting of musculature which resulted in her nearly complete immobilization. During hospitalization for diagnosis of this myopathy, the patient developed pleuritic chest pain followed by clinical evidence of thrombophlebitis of the right leg. A chest x-ray showed a slight infiltrate in the right base; and a total lactate dehydrogenase determination reached 2081 international units (heat stable was 810 units) before falling to normal. A lung scan was not done.

The patient was placed in deep Trendelenburg position and treated with intravenously administered heparin. Recovery was unremarkable and she was discharged on dicumarol.

The prothrombin time, however, did not consistently remain in therapeutic range, and six weeks after discharge the patient again developed thrombophlebitis of her leg and shortness of breath. Pleuritic chest pain was present and a chest x-ray suggested the presence of pulmonary infarct on the left. Physical examination revealed dullness to percussion over this area, and a lung scan showed some diminution in radioactivity of the left lung. Lactic dehydrogenase determinations were not elevated, and the patient again responded to rest, heparin and heat packs. She has been asymptomatic since discharge on anticoagulants.

I feel that the most important points to emphasize here are that the clinical and laboratory findings do not always correlate with each other and that pulmonary embolism remains largely a clinical diagnosis based on a high degree of suspicion.

Historical

Läennec[2] described pulmonary apoplexy in 1819 as several small swollen indurations, usually very dark red and occurring in each lung in patients dying from cardiac lesions. In 1855 Rokitansky[3] postulated the embolic origin of these "hemorrhagic infarcts," but it remained for Virchow[4] in 1856 to place foreign bodies in the veins of dogs and to recover these from the pulmonary arteries. Homans[5] in 1934 associated thrombosis with stasis in leg veins, and Hampton and Castleman[6] explored the situation in 1940 and concluded that pulmonary thrombo-embolism occurred commonly in debilitated, old and cardiac patients and was not exclusively a post-surgical disease.

Incidence

Pulmonary embolism accounts for over 300,000 hospital admissions each year; the yearly death rate in the United States is about 47,000 persons, although three times more deaths may occur in which pulmonary embolism has played a significant role.[7] Uhland[8] reported on 981 consecutive autopsies in a general hospital and found 118 cases of pulmonary embolism (12%), while Smith[9] reviewed the autopsies at Peter Bent Bringham in 1963 and confirmed this finding. Emboli were of various ages and sizes in 75% of the cases and were located in more than one region of the lung in the majority of patients. Wagner[10] found most of the emboli in the lower lung fields (60% to the right and 52% to the left), and Smith observed only 10% of the emboli to be associated with pulmonary infarction. Boyd[11] showed that 85% of fatal pulmonary embolism occurred in patients older than forty years and 60% in patients older than sixty.

The experience at Hennepin County General Hospital has shown that in the past 18 months, of the 717 autopsies performed, pulmonary embolism was regarded as the primary cause of death in four percent. This does not represent all deaths in the hospital and does include the medical examiner cases.

The Embolus

It is general consensus that an embolus from the heart or peripheral vein is the primary lesion in pulmonary thrombo-embolic disease.[11,12] Many authors

have sought to define the exact nature of such an embolus, the conditions from which it arose, and its effect on the pulmonary vasculature. These findings become of basic importance in the management of the patient.

Pneumonectomy is well tolerated in the normal man, tidal volume and oxygen exchange remaining nearly normal.[13] Why then should a pulmonary embolus be so disastrous? First, the usual candidate for a pulmonary embolus is not a normal man, but one who has underlying cardiac and/or respiratory disease. Second, Gorham[14] found that in 85% of cases at autopsy, pulmonary emboli were present in the opposite lung from the larger lesion. Third, Dexter[15] showed that by introducing small beads into the arteriolar branches of the pulmonary artery, he was able to produce a marked vasoconstriction, the result of secondary reflex mechanisms. This latter phenomenon has also been shown by Moore et al.[16] who were able to markedly reduce mortality in dogs subjected to embolization by pretreatment with ganglionic blocking agents. The subsequent vasodilatation allowed emboli to escape from the arteriolar bed into the capillary bed which, with its vastly larger total volume, required much more embolization to produce the same degree of disability. The vasoconstrictor long implicated in man has been serotonin, presumably released from the clot wedged into the pulmonic tree. This, then, plus the effect of the mechanical obstruction, the bilateral lesion, and the previously injured lung account for the high morbidity with a pulmonary embolus.

The exact predisposing circumstances to emboli formation are at best confusing. Slowing of the blood per se will usually not cause thrombus formation but this, combined with interference of the clotting mechanism and/or the structure of the vascular endothelium, can produce clot. Deykin in an excellent article on thrombogenesis[17] has suggested that some undetermined factors activate the intrinsic coagulation mechanism, producing a "hypercoagulable state," which, combined with stasis, results in formation of a red thrombus. The stasis in turn becomes important because it prevents dilution of the activated coagulation factors and their clearance by the liver.

Actual clotting of blood may be increased in many clinical situations: hemolytic states, acidosis, pregnancy, and endotoxin shock, to mention the more common. Blood flow is markedly slowed in cases of arterial hypotension, arteriolar vasoconstriction, histamine dilatation of all capillaries simultaneously, and opening of arteriovenous shunts. One can easily postulate how any combination of the above could cause red thrombus formation.

Many disease states predispose to and result in an increased incidence of pulmonary embolism: increasing age, confinement to bed, congestive heart failure, trauma, chronic thrombophlebitis, chronic lung disease, hemiparesis, chronic pyelonephritis, the postoperative state and subacute bacterial endocarditis. These are mentioned to persuade the reader to consider pulmonary emboli as the cause of unexplained dyspnea, fever, tachycardia or hemoptysis in such clinical situations where early recognition and treatment of embolism is very important.

Clinical Diagnosis

The clinical diagnosis of a significant pulmonary thrombo-embolic disorder depends on suspecting the existence of the disease and then correlating the multitude of findings that may exist. The classic triad of shortness of breath, chest pain, and hemoptysis is found in only three percent of major embolic episodes.[18] The Table shows that death is not always immediate, leaving time for careful diagnosis and institution of therapy.

TABLE*

Time from Onset to Death	Percent Cases
10 min. or less	41
15 min.	3
15 min. to 2 hrs.	22
2 hrs. to 12 hrs	8
12 hrs. to 24 hrs.	8
24 hrs. to 48 hrs.	6
3 days to 14 days	7
	(100 cases)

*From Gorham, L. W.[14]

The most common mistaken diagnosis is acute myocardial infarction; the second is stroke, because of the frequent picture of collapse, convulsion and hemiplegia.

Physical Examination

Particular physical findings have been appreciated in patients having an acute pulmonary thrombo-embolism. An initial pulsation in the second left intercostal space may be present because of the obstruction of the pulmonary artery. Many authors have noted a greatly accented pulmonary second sound which disappears with the appearance of right heart failure. Rales are uncommon. A pseudopericardial friction rub in the left second intercostal space may be present and may be confused with that occurring in myocardial infarction. Partial stenosis of the pulmonary artery by the obstructing embolus may produce a systolic murmur in the pulmonic area. An interscapular bruit is a rare finding but has been found in cases in which an embolus overrides the bifurcation of the pulmonary artery. The lung affected by an embolus in its main pulmonary artery may exhibit diminished expansion and an area of increased cardiac dullness to the right of the sternum, apparently due to acute right heart failure. Distended neck veins, a gallop rhythm, and an enlarged liver are frequent findings if acute right heart failure is present. Furthermore, cyanosis, pallor, dyspnea, apprehension, and tachypnea are also common. The disease should be particularly suspected if phlebitis is present (with or without the aid of Homan's sign[20] or the Lowenberg test,[21]) if the patient is febrile or if a pulmonary consolidation is present.

X-Ray Findings

There is no pathognomonic radiologic sign of pulmonary embolism. X-rays help if they are positive for any of the following signs as outlined by Fleischner:[22]

1. Oligemia of the lung fields.
2. Pleonema of the contralateral lung.
3. Evidence of right ventricular enlargement.
4. Dilated hilar arteries.
5. Dilated pulmonary artery trunk.
6. Right-sided inflow stasis with dilatation of the azygous vein and superior vena cava.

The pulmonary infarct is probably the most distinct sign of pulmonary embolus, occurring as a spindle-shaped consolidation along a pleural surface. The classically described "triangular shadow" is uncommonly seen because of the rich pulmonary collateral blood supply.[23]

Electrocardiographic Findings

The electrocardiographic evidence for pulmonary embolism is very useful but not specific. Only 10% to 20% of patients with pulmonary embolism will have electrocardiographic changes consistent with their disease;[24] however, many non-embolic diseases can be ruled out.

The principal findings include a deep S wave in Leads I, V_5 and V_6 with high-peaked P waves in Leads II and III representing acute cor pulmonale; a prominent Q wave in III with inversion of the T wave in II, III and the inner right-sided precordial leads; ST segment depression in I, II, III with staircase ascent of ST in II, suggestive of coronary insufficiency; and acute right axis deviation. Other more non-specific findings include sinus tachycardia (48%), sudden onset of arrhythmia (38%), conduction disturbance (5%), S wave in I, II, III (5%), and clockwise rotation of the heart (5%).

Laboratory Findings

Snodgrass et al.[25] have reported on the value of a triad of laboratory results: the lactic dehydrogenase (LDH), the serum glutamic oxylacetic transaminase (SGOT) and the serum bilirubin, in pulmonary thrombo-embolism. These investigators showed that the serum glutamic oxylacetic transaminase was occasionally elevated because of acute liver congestion but in most cases remained normal, while the lactic dehydrogenase was elevated in 97% and the serum bilirubin in 73% of autopsy-proved cases. Amador[26] measured lactic dehydrogenase by the forward (lactate-to-pyruvate) spectrophotometric method and found an extremely close correlation between an elevated lactic dehydrogenase and a positive lung scan. He also found normal lactic dehydrogenase values in diseases that predisposed to pulmonary embolism, such as congestive heart failure, trauma, thrombophlebitis and the postoperative state, and recommended following patients predisposed to embolic disease with lactic dehydrogenase determination to detect early signs of embolic infarction.

Lung Scan

A recent innovation for diagnosis of pulmonary embolism is radioisotope lung scanning as described by Wagner,[27] whereby radio-iodinated human serum albumin is injected intravenously and accumulates in the lungs. The positive pulmonary scan reveals areas of underperfusion and becomes especially important if there is no infiltrate on chest x-ray. Many have criticized the procedure because it cannot conclusively confirm the diagnosis and many false positive and negative studies occur;[28] however, the lung scan is safe, easy, and relatively economical; also it is more accurate than pulmonary angiography in detecting the small, peripheral or multiple lesions and can be used repeatedly in the same patient to follow return of pulmonary blood flow.[29]

Angiography

Simon and Sasahara[30] have described the technique of selective pulmonary angiography for the diagnosis of pulmonary emboli and emphasize the necessity for making a definitive diagnosis if surgical treatment is contemplated. Multiple angiographic features were noted—among them: obstruction of a pulmonary artery, irregular filling defects and plaques along vessel walls, regional decrease of flow rate of contrast medium, avascular areas, and

proximal dilatation of arteries with emboli. Sautter[31] has performed 150 pulmonary angiograms annually for the past two years in patients with suspected pulmonary embolism and reports a 90% incidence of positive studies. He stresses his unwillingness to operate and/or use the newer fibrinolytic agents without initial angiographic proof of existence of the embolus.

Pulmonary Function

Robin[32] has advocated measurement of the difference in the arterial and end-tidal alveolar carbon dioxide tensions. Any discrepancy greater than three mm. mercury is considered significant and suggests pulmonary embolism.

He also noted arterial oxygen unsaturation in patients with pulmonary embolism (63-90% in his series), an extremely uncommon finding in patients with acute myocardial infarction.

Natural History of the Disease

Multiple minute pulmonary emboli occur throughout a lifetime and remain inconsequential. But the embolus becomes significant when it occludes a large portion of the lungs (estimated at over 60 percent), when it causes reflex vasoconstriction, or when it produces pulmonary infarction. Sautter[33] has documented spontaneous resolution of pulmonary emboli in eight cases and noted resolution in as little as eleven days and as long as 128 days. Wagner[29] has demonstrated nearly complete return of pulmonary flow in most cases in four months.

Many emboli do not resolve, however, and their[8] effect is cumulative, eventually evolving to pulmonary hypertension.[34] In the acute state, Del Guercio[35] has shown that death is likely in the patient with a mean right ventricular pressure greater than 22 mm. mercury secondary to pulmonary embolus. Hopefully, earlier diagnosis and consequent earlier therapy will decrease the mortality rate.

Management

Trendelenburg[36] performed the first pulmonary embolectomy in 1908. Management falls into three broad categories: preventive, medical, and surgical, but all are interrelated; for it is in the best interest of the patient that medical and surgical teams not isolate their therapeutic armamentarium.

Prophylactically, the prevention of immobilization, hemoconcentration and vascular stasis is important. Medically, heparin, given intravenously, appears to be the drug of choice despite the lack of carefully controlled studies on its efficacy.[38] Its rapid onset of action, its easy reversibility, and its antiserotonin and undetermined antiplatelet agglutination action make it ideal in the therapy of pulmonary embolism. Local heat therapy and dextran for peripheral thrombophlebitis, bed rest in Trendelenburg position, and anticoagulation with bishydroxycoumarin are generally accepted measures.

Direct embolectomy was greatly advanced with the advent of successful cardiopulmonary bypass,[39,40] but inferior vena caval ligation has remained the procedure of choice for the patient tolerating his pulmonary embolus well, in whom recurrence is imminent or in whom the disease is bilateral.[41]

More recently an enzyme, urokinase, has been used for the treatment of pulmonary emboli.[42] This is a potent plasminogen activator which can produce clot lysis in vitro and in vivo and has been shown by Sautter to hasten

the lytic process in emboli. In his hands, the infusion of urokinase was a benign procedure and produced dramatic results in thirty patients with pulmonary emboli.

Conclusion

Successful therapy of pulmonary embolism depends on successful diagnosis of the disease. The symptomatic patient cannot usually tolerate further insult to his pulmonary vasculature. Many newer methods for diagnosis and for therapy are at our disposal and we must be prepared to use these if we are to successfully lower current incidence and mortality of pulmonary embolic disease.

Cybernetics and Prostheses

There is some work being done on artificial limbs in Russia, in the United States, and elsewhere by a group to which I belong. This work is much more interesting in principle and really makes use of cybernetical ideas.

Let us suppose that a man has lost a hand at the wrist. He has lost a few muscles that serve chiefly to spread the fingers and to bring them together again, but the greater part of the muscles that normally move the hand and the fingers are still intact in the stump of the forearm. When they are contracted, they move no hand and fingers, but they do produce certain electrical effects known as action potentials. These can be picked up by appropriate electrodes and can be amplified and combined by transistor circuits. They can be made to control the motions of an artificial hand through electric motors, which derive their power through appropriate electric batteries or accumulators, but the signals controlling them are sent through transistor circuits.

Such artificial hands have already been made in Russia, and they have even permitted some hand amputees to go back to effective work. This result is facilitated by the circumstance that the same nervous signal which was effective in producing a muscular contraction before the amputation will still be effective in controlling the motor moving the artificial hand.

Thus there is a new engineering of prostheses possible, and it will involve the construction of systems of a mixed nature, involving both human and mechanical parts.*

Mr. President—Your Health*

James A. Garfield, 1831-1881

The health history of our twentieth President, James A. Garfield, can be telescoped into four distinct onslaughts against his constitutional integrity.

The first occurred when young James was a husky fifteen-year-old working on a canal boat. While still lacking the coordination and agility required for his job he accidentally tumbled into the water fourteen times. After his last submersion he became so ill with ague that he had to be sent home to be nursed by his mother. Her home remedies not availing, a distant doctor was sent for, who proceeded to ptyalize the stricken youth with heavy doses of calomel; whereupon young James developed a hard, inflamed bunch on his left side, so sensitive as to practically immobilize him: an "ague-cake" his mother called it. Only after weeks of confinement to his bed did he fully recover his pristine health.

The second assault against Garfield's constitution consisted of camp fever, that ubiquitous scourge of army life, while he was a member of the 42nd Ohio Regiment in the Civil War. For lack of specific treatment, such ineffectual modalities were resorted to as bathing, soaking the feet, and swallowing "hygiene pills." For Garfield this trying period of military service was not only a debilitating but also a disillusioning one. "At the end of his army service he had nothing to show except the rank of brigadier general, a damaged constitution, and a profound distrust of the ability and real political loyalty of the officers under whom he served."

During the presidency Garfield's constitution registered the full impact of the stress and strain imposed by the political responsibilities and moral obligations of his high office. The price exacted was obstinate insomnia which was finally overcome only by increased outdoorsmanship: riding and walking in the open air.

Finally, in a Washington railroad station as he was preparing to depart on a vacation journey July 2, 1881, two assassin's bullets presented the fourth challenge to Garfield's physical integrity. One bullet merely grazed his right arm; the other tore into his back, ravaging his interior with baffling and sinister complications for over two months before death released him from his crucible of suffering.

"The immediate cause of Garfield's death was for some time a matter of dispute among physicians, but those who were in charge . . . made a post-mortem examination the day after his death. The operation was performed by Dr. Lamb, and it was found that the ball, after fracturing the right eleventh rib, had passed through the spinal column in front of the spinal canal. It had fractured the body of the first lumbar vertebra, driving a number of small fragments of bone into the adjacent soft parts, and had lodged just below the pancreas . . . and behind the peritoneum, where it had become completely encysted. The immediate cause of death was a secondary hemorrhage from one of the mesenteric arteries adjoining the track of the ball.

"The primary cause was septicemia with metastatic abscesses. Contributing causes were: (1) rupture of a mesenteric artery by the bullet; (2) bronchopneumonia, and (3) coronary thrombosis."

*With acknowledgment to and quotations from Karl C. Wold, M.D.: Mr. President—How Is Your Health? Bruce Pub., 1948.

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

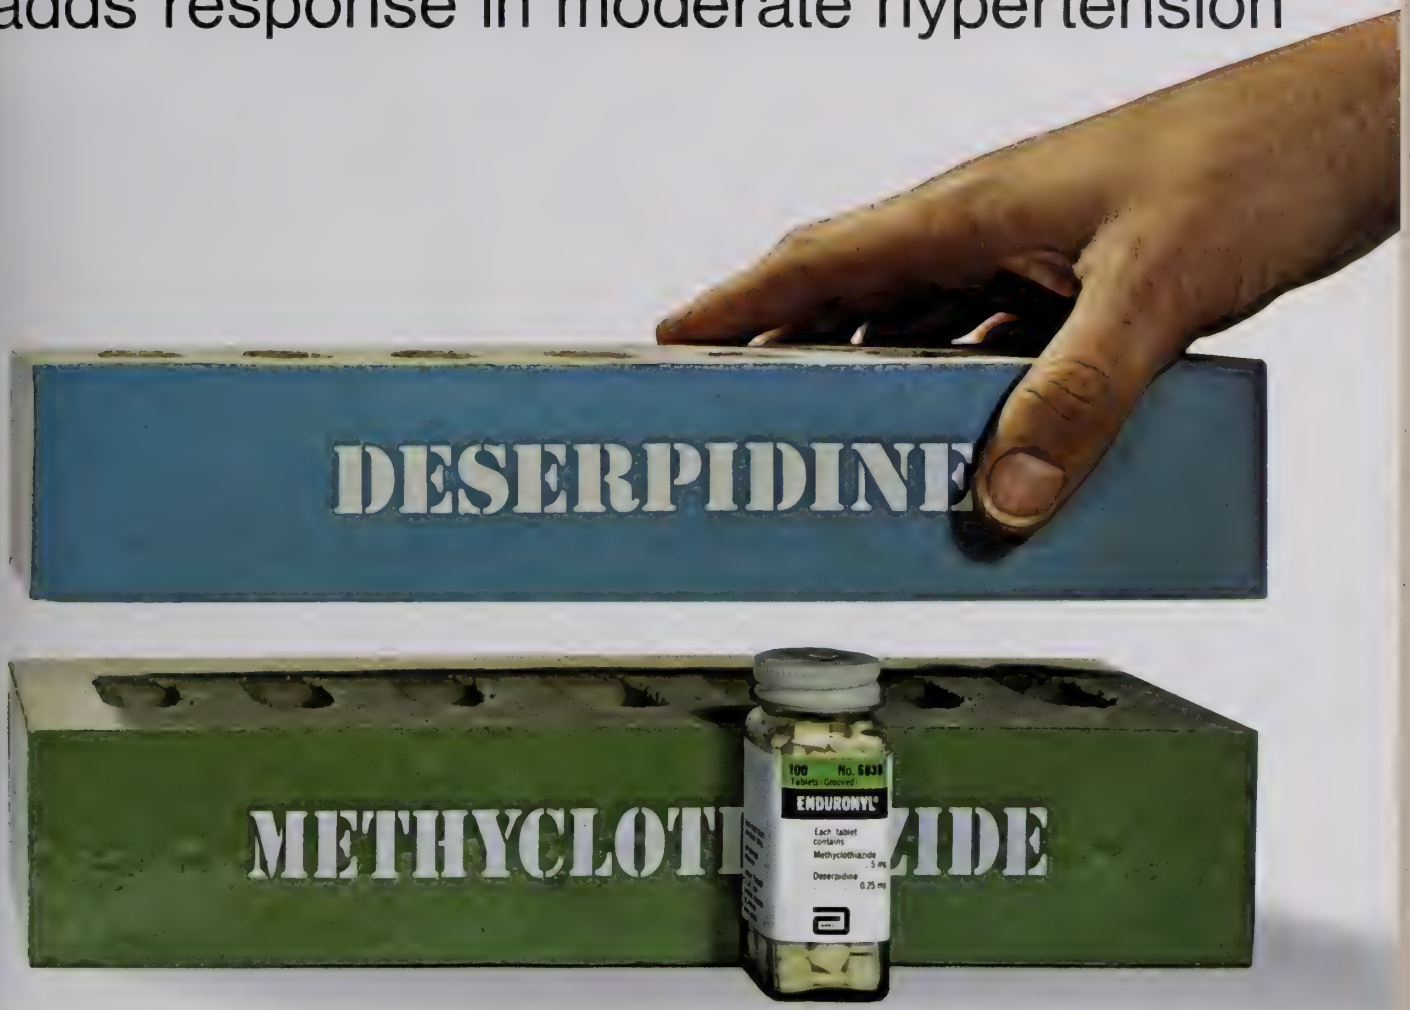
The therapeutic action is smooth, and persits for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

Of course, as with all thiazides, supplemental dietary potassium should also be considered.

Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON®



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

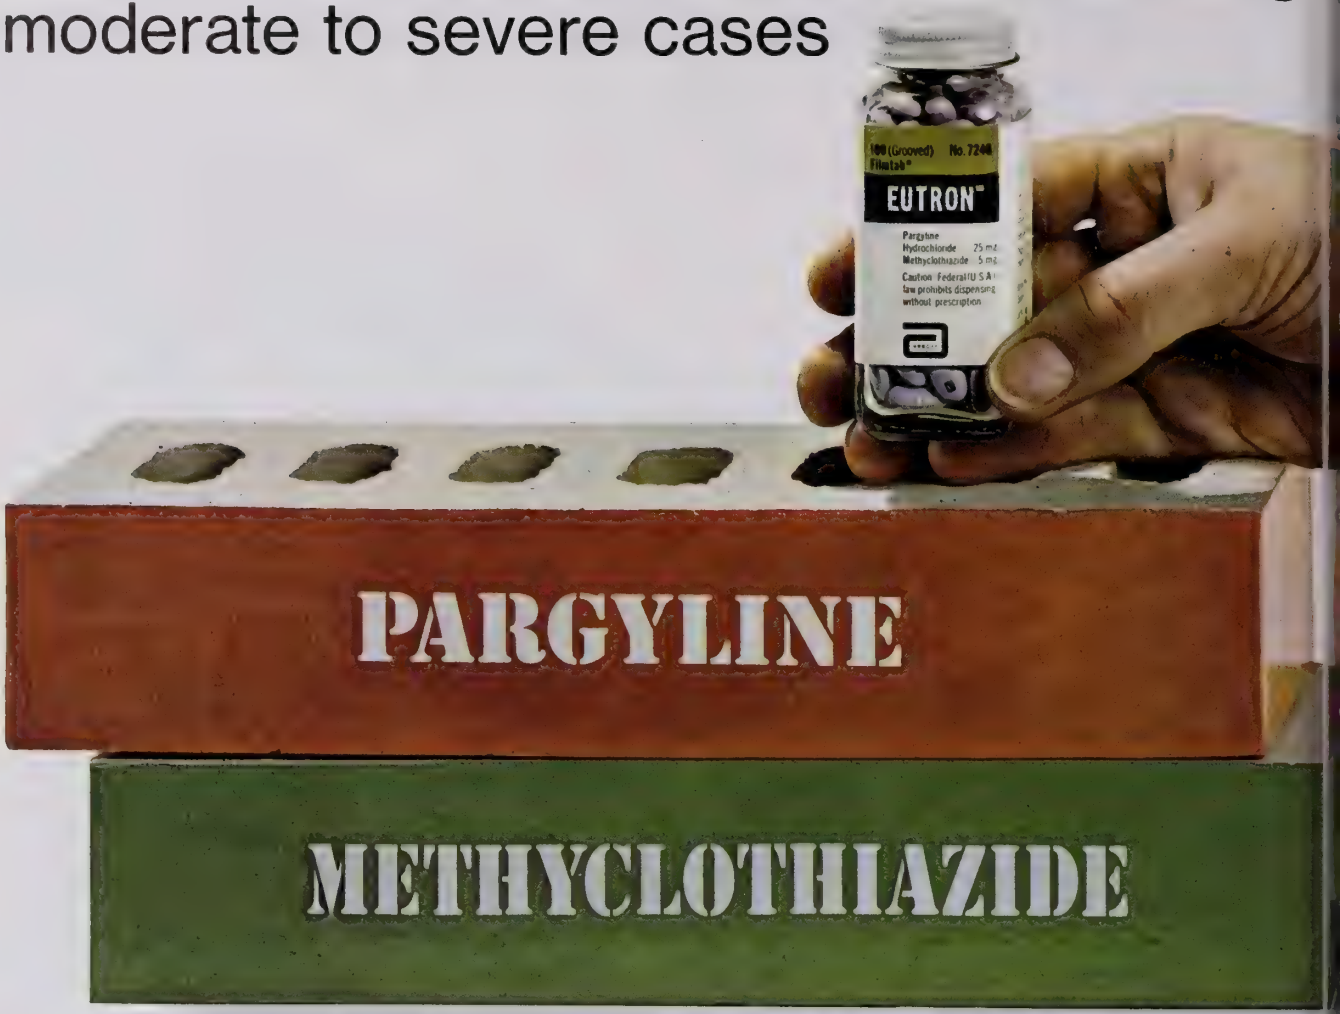
Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®

METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.



MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications: For treatment of patients with moderate to severe hypertension, especially those with severe diastolic hypertension. Not recommended for patients with mild or labile hypertension amendable to therapy with sedatives and/or thiazide diuretics alone. It is desirable to establish the dosage of Eutron by administering component drugs separately.

Contraindications: Pheochromocytoma, advanced renal disease, increasing renal dysfunction, paranoid schizophrenia and hyperthyroidism. Hepatic coma has been reported as consequence of hypokalemia with thiazide therapy. Until further experience is gained not recommended for patients with malignant hypertension, children under 12, or pregnant patients.

Concomitant use of the following is contraindicated: other monoamine oxidase inhibitors; parenteral forms of reserpine or guanethidine; sympathomimetic drugs; foods high in tyramine such as cheese; imipramine and amitriptyline, or similar antidepressants; methyldopa. 2 week interval should separate therapy and use of these agents.

Methyclothiazide is contraindicated in patients with known sensitivity to thiazides.

Warnings: Pargyline hydrochloride is a monoamine oxidase inhibitor. Warn patients against eating cheese, and using alcohol, proprietary drugs or other medication without the knowledge of the physician. When indicated, alcohol, narcotics (meperidine should be avoided), antihistamines, barbiturates, chloral hydrate, and other hypnotics, sedatives, tranquilizers, or caffeine, may be used cautiously in reduced dosage. In emergency surgery ¼ to ⅕ the usual dose of narcotics, analgesics, and other premedications should be used avoiding parenteral administration where possible. Carefully adjust dose of anesthetics to response of patient. Withdraw pargyline two weeks before elective surgery.

Warn patients about the possibility of postural hypotension. Those with angina or coronary artery disease should not increase physical activity with an improvement in well being. Pargyline may lower blood sugar.

Avoid use of enteric-coated potassium tablets, as these may induce serious or fatal small-bowel lesions consisting of stenosis with or without ulceration. These small-bowel lesions have caused obstruction, hemorrhage and perforation frequently requiring surgery. Medication should be discontinued immediately if abdominal pain, distension, nausea, vomiting or GI bleeding occurs. These products contain no added potassium salts and if added potassium intake is desired, dietary supplementation is recommended. Coated potassium tablets should be reserved for cautious use when adequate dietary supplementation is impractical. In patients with a history of allergy or asthma the possibility of sensitivity reactions should be considered.

Precautions: Measure blood pressure while patient is standing to determine antihypertensive effect. Use with caution in hyperactive or hyperexcitable persons. Such persons may show increased restlessness and agitation. Withdraw drug during acute febrile illness. Watch patients with impaired renal function for increasing drug effects or elevation of BUN and other evidence of progressive renal failure; withdraw drug if such alterations persist and progress. Use with caution in patients with liver disease. As with all new drugs, complete blood counts, urinalyses, and liver function tests should be performed periodically. With prolonged therapy, examine patients for change in color perception, visual fields and fundi. Also reported have been: blood dyscrasias including thrombocytopenia with purpura, agranulocytosis and aplastic anemia; elevations of BUN, serum uric acid, or blood sugar. Symptomatic gout may be induced. In surgical patients thiazides may reduce response to vasopressors and increase response to tubocurarine.

Adverse Reactions: Pargyline may be associated with orthostatic hypotension. Mild constipation, slight edema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence, delayed ejaculation, rash, and purpura have been encountered with pargyline. Hyperexcitability, increased neuromuscular activity (muscle twitching) and other extrapyramidal symptoms have been reported in a few patients with reduced cardiac reserve.

During intensive or prolonged therapy, guard against hypochloremic alkalosis and hypokalemia (especially the latter if patient is on digitalis). Observe all patients for signs of hyponatremia ("low salt" syndrome).

Reported thiazide reactions also include anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, and pancreatitis. Nocturia has been observed with the combination. 801438

TM-TRADEMARK

Dislocation of the Jaw

Mochlicus

The jaw-bone is often slightly displaced, and is restored again; it is dislocated but rarely, especially in gaping; in fact, the bone is never dislocated unless it slips while the mouth is opened wide. It slips, however, the more readily from its ligaments being oblique, supple, and of a yielding nature. The symptoms are: the lower jaw protrudes, it is distorted to the side opposite the dislocation, and the patient cannot shut his mouth; when both sides are dislocated, the jaw projects more, the mouth can be less shut, but there is no distortion; this is shown by the rows of teeth in the upper and lower jaw corresponding with one another. If, then, both sides be dislocated, and not immediately reduced, the patient for the most part dies on the tenth day, with symptoms of continued fever, stupor, and coma, for the muscles there induce such effects; there is disorder of the bowels attended with scanty and unmixed dejections; and the vomitings, if any, are of the same character. The other variety is less troublesome. The method of reduction is the same in both: The patient being laid down or seated, the physician is to take hold of his head, and grasping both sides of the jaw-bone with both hands, within and without, he must perform three maneuvers at once,—rectify the position of the jaw, push it backward, and shut the mouth. The treatment should consist of soothing applications, position, and applying a suitable bandage to support the jaw-bone, so as to cooperate with the reduction.—*Hippocrates*

Yellow Fever in Philadelphia in 1793

When yellow fever ravaged the city of Philadelphia in 1793 scenes occurred that were reminiscent of those described by Boccaccio in Florence. A bookseller and publisher, Mathew Carey, gave a vivid account of them:

"The consternation of the people of Philadelphia at this period was carried beyond all bounds. Dismay and affright were visible in almost every person's countenance. Most of those who could by any means make it convenient, fled from the city. Of those who remained, many shut themselves up in their houses, and were afraid to walk the streets. The smoke of tobacco being regarded as a preventative, many persons, even women and small boys, had segars almost constantly in their mouthes. Others placing full confidence in garlic, chewed it almost the whole day; some kept it in their pockets and shoes. . . . Those who ventured abroad, had handkerchiefs or sponges impregnated with vinegar or camphor at their noses, or smelling-bottles full of the thieves' vinegar. Others carried pieces of tarred rope in their hands or pockets, or camphor bags tied round their necks. . . . Many never walked on the foot path, but went into the middle of the streets, to avoid being infected in passing by houses wherein people had died. . . . The old custom of shaking hands fell into such general disuse, that many shrunk back with affright at even the offer of a hand. And many valued themselves highly on the skill and address with which they got to windward of every person whom they met."*

*Henry Sigerist, M.D.: Medicine and Human Welfare, 1941.

No parent should spend all of his time in the garden of a child's life digging up weeds; there is always the danger of scratching out flowers not above the ground.—*Cominco*

Law and Medicine

Compelled Medical Opinion Testimony

BARLOW SMITH, LL.B., M.D.*
Minneapolis, Minnesota

EVERY PERSON has a legal obligation to testify in court to what he has observed in relation to a disputed issue of fact. Thus a physician must give testimony regarding the injuries he observed on the victim of a crime of violence, not because he is an expert in physical examination but solely because he was there to observe.

Courts have the power to punish failure to appear and respond as contempt of court. Here the duty to testify is as a citizen, not as a physician.

The question arises when a physician may be legally compelled to give his medical opinion.

The rule in England was that an expert may not be compelled to give expert opinion testimony in the absence of a contract to do so between him and the party for whom he is to testify**

In the United States most jurisdictions subscribe to one of two general rules: (1) the court cannot compel an expert to testify against his will, and (2) an expert cannot be compelled to testify if he would have to make special study or preparation in order to give his opinion.†

But, when an expert has already performed an examination, he may then be compelled to testify not just to the facts but also to his opinion in jurisdictions following the second rule‡ unless a privilege exists which would require exclusion of the evidence.

For example, it was held in California that a physician hired by a party's attorney to conduct an examination was an agent of the attorney; hence, his report to the latter was privileged under the rule of evidence excluding testimony of communications between attorney and client.§

In such a jurisdiction no different situation exists when the expert is himself a party. Recently an intermediate appellate court in New York ruled that a defendant in a malpractice action may not be compelled to testify even about facts within his knowledge as to proper medical practice and whether

**Webb v. Page, 1 Car. & K. 23(1843).

†Kranshaar Bros. v. Thorpe, 296 N.Y. 223, 72 N.E.2d 165(1947).

‡Neilsen v. Brown, 374 P2d 896(Ore., 1962).

§Porterfield, Right to Subpoena Expert Testimony and Fees Required to be Paid Therefore, 5 Hastings L.J. 50(1953).

his actions deviated therefrom when the question requires his expert opinion.*

In states with discovery procedures for litigants in civil cases, besides being summoned to testify at the trial of a lawsuit, a witness may be summoned to give a deposition. This is an informal meeting of attorneys and witnesses and a person empowered to administer oaths such as a notary public and a stenographer who records questions propounded by the attorneys to the deponent under oath. Failure to appear when subpoenaed for a deposition is punishable as a contempt.

Rule 26 of the Federal Rules of Civil Procedure are very broad: *any* person may be subpoenaed for deposition, not just a party to the lawsuit. However, at least 15 states with rules of procedure modeled after the Federal Rules provide that expert opinion cannot be compelled by deposition. Minnesota Rules of Civil Practice 26.01 makes "any person" subject to subpoena for deposition, but under 26.02 no expert opinion may be required.

Rule 33 pertaining to interrogatories of parties to a lawsuit and Rule 34 pertaining to discovery and production of documents for inspection, copying or photographing make the restrictions of Rule 26.02 applicable to those procedures.**

However, the leading Minnesota case dealing with trial testimony (unrelated to discovery procedures) places no limitation on compelling expert witnesses to give opinion evidence: ". . . I(n) this state no witness can refuse to answer a question on the ground that his answer will be what is known as expert evidence; and this, whether he has been summoned or paid as an expert witness or not."† Inasmuch as this decision was rendered 80 years ago in a murder case and has been only briefly mentioned by the Minnesota Supreme Court in a single subsequent decision, its authority may be ripe for challenge.

It's the Law

Pregnancy After Sterilization Operation Is Cause For Suit

The patient, who became pregnant after having undergone a sterilization operation, won an award against the physicians who performed the operation.

The patient had nine children. The physicians told her that having more children would aggravate an existing kidney and bladder condition. They recommended an operation for removal of a portion of the fallopian tubes, which would accomplish sterilization. The patient consented, and the operation was performed. She became pregnant 10 months later.

The patient alleged that the operation failed because of an insufficiency in the procedure. She also claimed that the physician failed to tell her that the operation did not offer complete assurance against becoming pregnant.

The physicians contended that regeneration of the fallopian tubes was out of their hands.

Damages are recoverable for expense of the pregnancy, delivery, and rearing of the child. A California intermediate appellate court ruled in favor of the patient.

Case Reference—Custodio v. Bauer, 59 Cal. Rptr. 463 Cal., May 24, 1967: Rehearing denied, June 13, 1967.
The Citation—15:10, August 12, 1967

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

up to 10-12 hours clear breathing on one tablet

If hypothyroidism leaves your patient feeling like this...

consider

LETTER®

(SODIUM LEVOTHYROXINE, ARMOUR) TABLETS

Synthetic Thyroid Replacement Therapy

Letter® provides all the advantages of the synthetically pure chemical sodium levothyroxine. Dosage is precise and potency is consistently uniform.

and

Letter® is micronized to provide maximum opportunity for full absorption and clinical response.

In addition Letter® is distinctively color coded with an identifying number stamped on each tablet to provide accurate dosage control.

Indications: Hypothyroid conditions. **Contraindications:** Thyrotoxicosis, acute myocardial infarctions unless associated with hypothyroidism. In hypothyroidism with hypoadrenalism coadministration of corticoids with LETTER® is recommended. **Precautions and Side Effects:** Excessive dosage may result in diarrhea, cramps, palpitation, nervousness, rapid pulse, sweating. If symptoms appear, discontinue medication for several days, then reinstitute at a lower level. Since myxedema patients with heart disease may suffer seriously from abrupt increases in dosage, caution should be exercised in adjusting dosage. **Dosage:** Generally, the initial adult dosage is 0.1 mg. daily. This may be increased in small increments every one to three weeks until proper metabolic balance is achieved. **Available:** Bottles of 100 tablets, in six potencies: 0.025 mg. (violet), 0.05 mg. (peach), 0.1 mg. (pink), 0.2 mg. (green), 0.3 mg. (yellow), and 0.5 mg. (white).

Abstracts, Briefs and Commentaries

GASTROINTESTINAL FUNCTION FOLLOWING VAGOTOMY AND PYLOROPLASTY

The authors reviewed 45 cases (eight patients with gastric ulcer and 37 with duodenal ulcer). The surgical procedure was total abdominal vagotomy and a Mikulicz pyloroplasty. The authors evaluated postoperative posture, peristalsis, and subsequent intestinal absorption of xylose.

Appropriate positioning (right lateral position) after operation results in adequate emptying during the adynamic phase of gastric function. This is begun immediately.

In as early as six hours the stomach empties, and intestinal motility and absorption are unimpaired. The absence of bowel sounds does not mean absence of peristalsis and is of no diagnostic value.

Routine gastric decompensation may be unnecessary. Perhaps a more generous attitude of oral intake might be feasible.

TUMORS OF THE PAROTID GLAND

During an 18-year period 153 cases of parotid tumors were seen at the M. D. Anderson Hospital, 42 benign and 111 malignant. Superficial lobectomy was done on all patients either to remove the tumor in its entirety or to get at the deeper lobe. Recommendation is made for inclusion of the first echelon of nodes (parotid and jugulodigastric) with the specimen. A simultaneous neck dissection is made with clinically positive nodes in cases where malignancies are discovered. Irradiation is given where residual or suspected tumor remains at the margins of resection.

Of the patients with a malignant tumor 53% were living and free of disease five years after surgery. However, only four of the 21 patients with histologically proven cervical metastases survived five years. Facial paralysis was an ominous sign when present prior to surgery. Eight of nine patients with this sign were dead as a result of their disease within 24 months. Only two of the 42 benign cases treated developed a recurrence.

MASSIVE UPPER GASTROINTESTINAL HEMORRHAGE DUE TO PANCREATITIS

Massive hemorrhage is most likely due to erosion of a large retroperitoneal vessel. Minor hemorrhage may result from gastritis, peptic ulcer, or varices. Two cases are presented.

The salient features of this syndrome are massive recurrent hemorrhage (melena), vomiting, and nonresponse to either medical or surgical treatment. Bleeding points may not be found at exploration. The serum amylase may not be elevated. There is no experience of ligation of large vessels in the necrotic pancreas. This complication occurs rather frequently in acute pancreatitis.

The physician should be suspicious of acute hemorrhagic pancreatitis in all instances of massive gastrointestinal bleeding.

Comment: The author is aware of a patient who, subsequent to pancreatitis, developed massive recurrent gastric hemorrhage. This was not helped by either medical or surgical treatment until successful ligation of an eroded artery in the gastric fundus.

CEREBRAL CREATINE PHOSPHOKINASE

These days serum creatine phosphokinase is getting a big play in clinical laboratories. The reasons for this are obvious. Heart muscle and skeletal muscle contain most of the creatine phosphokinase in the body, while the liver has none. This happy state of distribution allows clinicians to distinguish which organ is in trouble. But it turns out that things aren't that clear-cut. A group of Englishmen from Newcastle General Hospital now tell us that about 15 of 21 patients with cerebral damage from head injuries, acute cerebrovascular accidents, and meningitis had high serum creatine phosphokinases. Which makes sense, for although the heart and skeletal muscle have most of the enzyme, the brain also contains generous amounts. But, and here is the catch, when the serum enzyme of these patients was fractionated, it was largely from muscle. As the authors say, "Why muscle-C.K. is often much increased in the serum in such cases remains unclear."

ALTERED LYMPHATIC DYNAMICS CAUSED BY CANCER METASTASES

Changes in lymphatic dynamics subsequent to metastases in the lymphatic vessels or nodes will alter the subsequent plan of treatment for cancer.

The normal lymphatic compartmental systems of the upper and lower extremity are described. There are numerous lymphatic-venous connections.

When blocked by neoplasm, the lymphatic flow may shift to other compartments. Awareness of this will allow proper surgical therapy. Often the bizarre lymphatic networks will completely bypass lymph nodes. The level or location of the block determines the nature of the collateral systems. The perivascular and perineural lymphatics may allow transport over great

distances. Dissemination of neoplasm via the lymphicovenous anastomoses probably occurs. Satellitosis (satellite dermal metastases as in melanoma) result from expansive dermal lymphatics secondary to major lymphatic obstruction.

NOW COFFEE

Man's habits, if overdone, sometimes produce unexpected diagnostic problems. Too many artificially sweetened soft drinks, for example, can cause a skin rash to erupt when the patient is exposed to light. And too many cigarettes can, among other things, lead to eosinophilia. Coffee? Well, coffee, when taken to excess, can produce a low grade irregular fever.[3] Doctor Hebart Reimann, in a recent JAMA article, tells the story of a 39-year-old housewife who for six months had a fever of 99 to 100.4, was unable to eat or sleep, became irritable, and lost 20 pounds. When she entered the hospital, her fever stopped. Doctor Reimann questioned her and found she drank 15 to 18 cups of coffee a day. When coffee was restricted, her temperature stayed normal, her appetite improved, her insomnia abated, and she gained five pounds.

NODOSA OR NOT NODOSA

Given a patient with migrating pulmonary infiltrates and persistent eosinophilia, what diagnosis should a physician consider—periarteritis nodosa or Loeffler's pneumonia? According to recent articles,[1,2] both are possibilities. Drs. Kinsella and Simpson of Springfield, Massachusetts, report a 61-year-old woman who, four years after a bout of "Loeffler's pneumonia," died of generalized vasculitis.[1] In 1965, Drs. Dines and Donoghue of the Mayo Clinic observed two patients, a 46-year-old farmer and a 34-year-old farmer's wife, with lung infiltrate and with 50 and 31 percent eosinophils respectively.[2] Both responded promptly to steroids, and the Mayo physicians diagnosed Loeffler's syndrome instead of periarteritis nodosa. How does one differentiate the two diseases? In periarteritis, long symptoms last longer, and patients are more likely to be anemic, to have renal disease, to cough up blood, to show pleural effusions, and to develop other problems that go with multisystem disease. When none of these signs or symptoms are present, time tells.

Richard L. Reece, M.D.
Minneapolis, Minnesota

What you take in is determined by what you put out.—*Forbes Epigrams*

She doesn't feel she "suffers" from hypertension

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either disease *or* therapy

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure[1]...at times to levels *below* those attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25
Prestabs®* Tablets

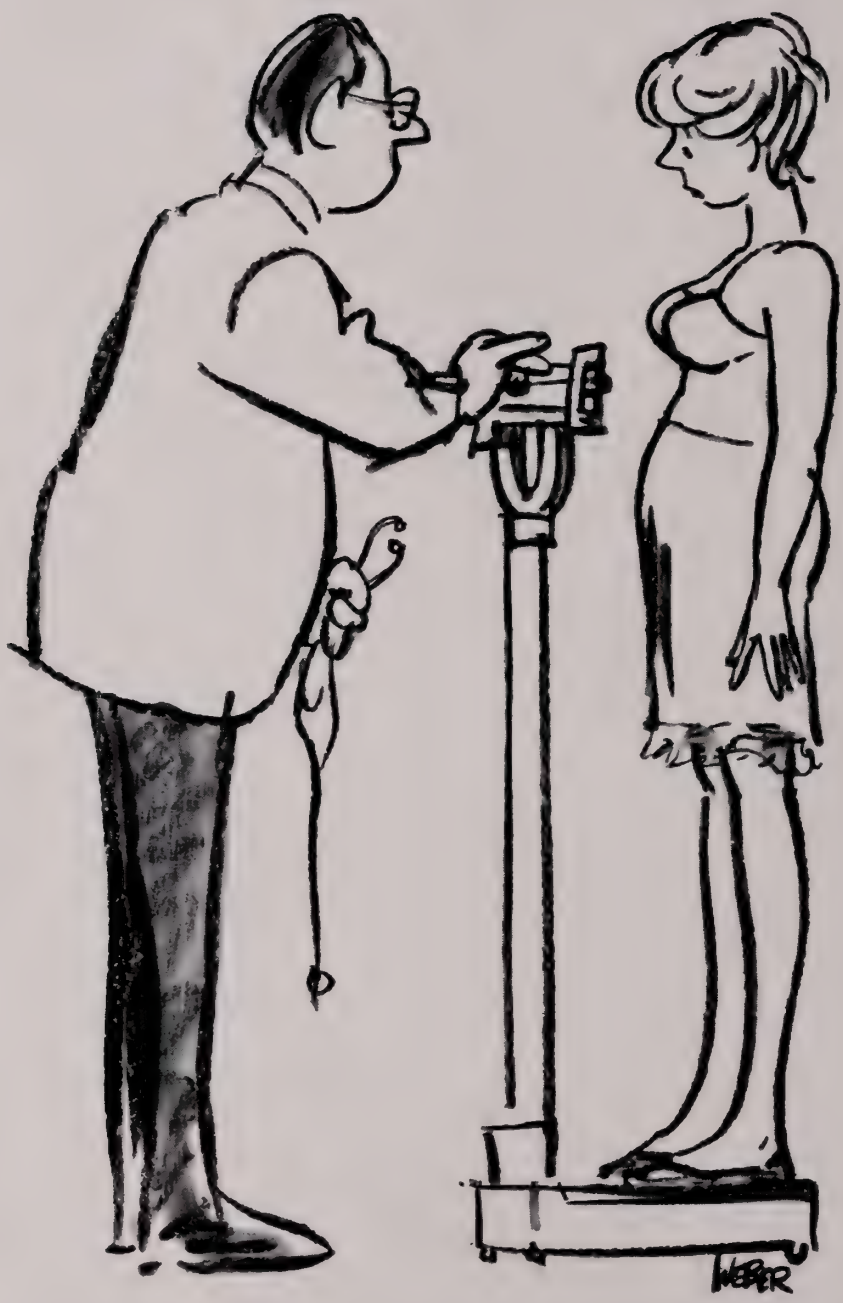
BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 25 mg. (⅜ gr.); Reserpine 0.1 mg.

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

Butiserpazide®-50
Prestabs®* Tablets

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.



---

*15 mg. of **Butisol** (butabarbital), plus the other ingredients, in outer layer; 15 mg. of **Butisol** (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyperuricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †**Warning:** May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: Penna. M. J.: **67**:35, 1964. 2. Coodley, E. L.: Curr. Ther. Res. **4**:460, 1962.

McNEIL

McNEIL LABORATORIES, INC.,
FORT WASHINGTON, PA.

"You're up ten pounds since your last physical. We're going to have to do something about that."

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain.* When a new dietary pattern must be established, consider the adjunctive use of BAMADEX SEQUELS. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, BAMADEX SEQUELS controls appetite throughout the day, usually with a single capsule daily.

Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.
Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.
Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Bamadex® Sequels®

Dextro-amphetamine sulfate (15 mg.) with Meprobamate (300 mg.) **Sustained Release Capsules**

Popular Fallacies

Medical Folklore Usually Wrong

While much of medical folklore is now obsolete and largely forgotten, there are still many completely erroneous beliefs about their health held by sizeable numbers of people in our so-called age of enlightenment.

Today's Health Guide, the American Medical Association's manual of health information for the American family, points out that grandma is not always wrong in her concepts of health. But she often is wrong.

The book lists some of the common misconceptions about health—

- Eating between meals is always harmful (untrue).
- Bad breath means disease (not so).
- Milk should not be taken at the same time as sour fruits (not so).
- Proteins and carbohydrates should not be eaten at the same meal (incorrect).
- Daily bowel movements are necessary for health (untrue).
- Pain in the back must indicate kidney disease (incorrect).
- Pain in the abdomen means an overloaded stomach (wrong).
- A laxative is good for abdominal pain (it is sometimes dangerous).
- Food kept in an open tin can is necessarily poisonous (not if properly refrigerated).
- Scales from scarlet fever and measles spread the disease (nose and throat secretions actually do).
- Sewer gas makes people sick (no—it's just unpleasant).
- Pimples and boils indicate bad blood (they are due to infections).
- Boric acid strengthens the eyes (it does not).
- Fried and highly seasoned foods are harmful (not in moderation).
- A cold can be broken up or cured (it cannot).
- You feed a cold and starve a fever (no).
- Eye muscle exercises will eliminate the need for glasses (a dangerous fallacy).
- Vegetarianism is good for health (it simply makes good nutrition more difficult).

Medical Men On Postage Stamps

Franz Donders (1818-1889), Dutch ophthalmologist, who studied conveyance of axes and accommodation, regeneration of cornea, hypermetropia, ametropia, and astigmatism, is credited with the discovery of clinical refraction and with the introduction of prismatic and cylindrical lenses for eyeglasses. A 1935 Netherlands postage stamp commemorates his notable achievements.

Theodor Bilharz (1825-1862), was a German physician and researcher in tropical diseases, particularly bilharziasis. In his capacity as helminthologist he identified the cause of certain endemic blood disorders as a trematode worm subsequently designated Bilharzia after its discoverer. In recognition and appreciation the United Arab Republic honored Bilharz on a postage stamp issued in 1962.

When death comes to me it will find me busy unless I am asleep. If I thought I was going to die tomorrow, I should nevertheless plant a tree today.—*Stephen Crane*

"Yes, Doctor, the pain is gone."

'EMPIRIN'® COMPOUND with CODEINE PHOSPHATE gr. 1/2 No. 3

Each tablet contains: Codeine Phosphate gr. ½ (Warning – May be habit forming), Phenacetin gr. 2½, Aspirin gr. 3½, Caffeine gr. ½.

Despite introduction of synthetic substitutes, efficacy of 'Empirin' Compound with Codeine remains unchallenged.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

An uncommon steroid for common inflammatory dermatoses

In everyday topical steroid therapy, Synalar produces rapid resolution of inflammation and itching in steroid-responsive dermatoses—and at relatively low cost to the patient.

Advanced molecular design enhances potency

Synalar combines the advantage of earlier corticosteroid compounds with unique structural innovations. As a result, preparations of Synalar 0.01% and Synalar 0.025% have been reported to be more potent topically and significantly more effective than hydrocortisone 1.0%. The unique fluocinolone acetonide molecule provides one of the most useful topical corticosteroids for everyday practice.

Impressive clinical results in a wide range of dermatologic problems

The clinical efficacy of Synalar has been extensively documented in the world literature. Commonly encountered diseases such as allergic and contact dermatitis, eczematous and seborrheic dermatitis, and neurodermatitis respond rapidly to Synalar, often where previous therapy with other topical corticosteroids has failed.

Low patient cost for wider usefulness

With Synalar, a high degree of efficacy does not mean high price. And—a small quantity goes a long way. Thus, your patients can often obtain the "economy" of a hydrocortisone preparation with the proved efficacy of a potent, truly advanced steroid.

Synalar®
fluocinolone acetonide

Turn page for contraindicati precautions and side effects.

For everyday topical steroid therapy

Synalar® 0.01%

fluocinolone acetonide provides economy in two practical dosage forms

For general use, the most economical and widely applicable concentration of Synalar is 0.01% Cream in a water-washable, vanishing cream base. Synalar Solution 0.01% is especially valuable in dermatoses involving moist, intertriginous areas or hairy sites where creams and ointments do not spread or penetrate readily. Synalar Solution is a unique dosage form—clear, nongreasy, cosmetically elegant.

Product Information

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. *Precautions:* Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time. *Side Effects:* Side effects are uncommon with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. In such cases the agent should be discontinued and appropriate measures taken. *Availability:* Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Solution 0.01%—20 and 60 cc. plastic squeeze bottles. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

Book Reviews

The problem of education is twofold: first to know, and then to utter. Everyone who lives any semblance of inner life thinks more nobly and profoundly than he speaks.—R. L. Stevenson

DIAGNOSTIC PROCEDURES IN GASTROENTEROLOGY—By Charles H. Brown, M.D. 438 pages, $19.00. The C. V. Mosby Company, St. Louis.

This monograph dealing with various phases of gastroenterology is divided into eight parts and is written by physicians from the Cleveland Clinic Foundation as a manual for the physician who wishes to increase his diagnostic ability and determine the variety of procedures that are carried out in the study of gastrointestinal diseases. It covers the medical as well as the surgical phases of this problem.

The minute details of technique are not enumerated and for that reason the book has more value to the individual who has already been initiated into the clinical phases of gastroenterology. For the student in the medical school or entering into his specialty, the details of technique are insufficient and it would be expected that other monographs should be used for that purpose.

A great many diagnostic hints and suggestions are provided and it was interesting to note that the patient who presents with multiple abdominal scars very often may be suffering from a conversion neurosis unless organic evidence of specific disease can be identified.

Supplemental instructions for the patient and supplementary diets are appended to the last hundred pages.

Carl O. Rice, M.D.
Minneapolis, Minnesota

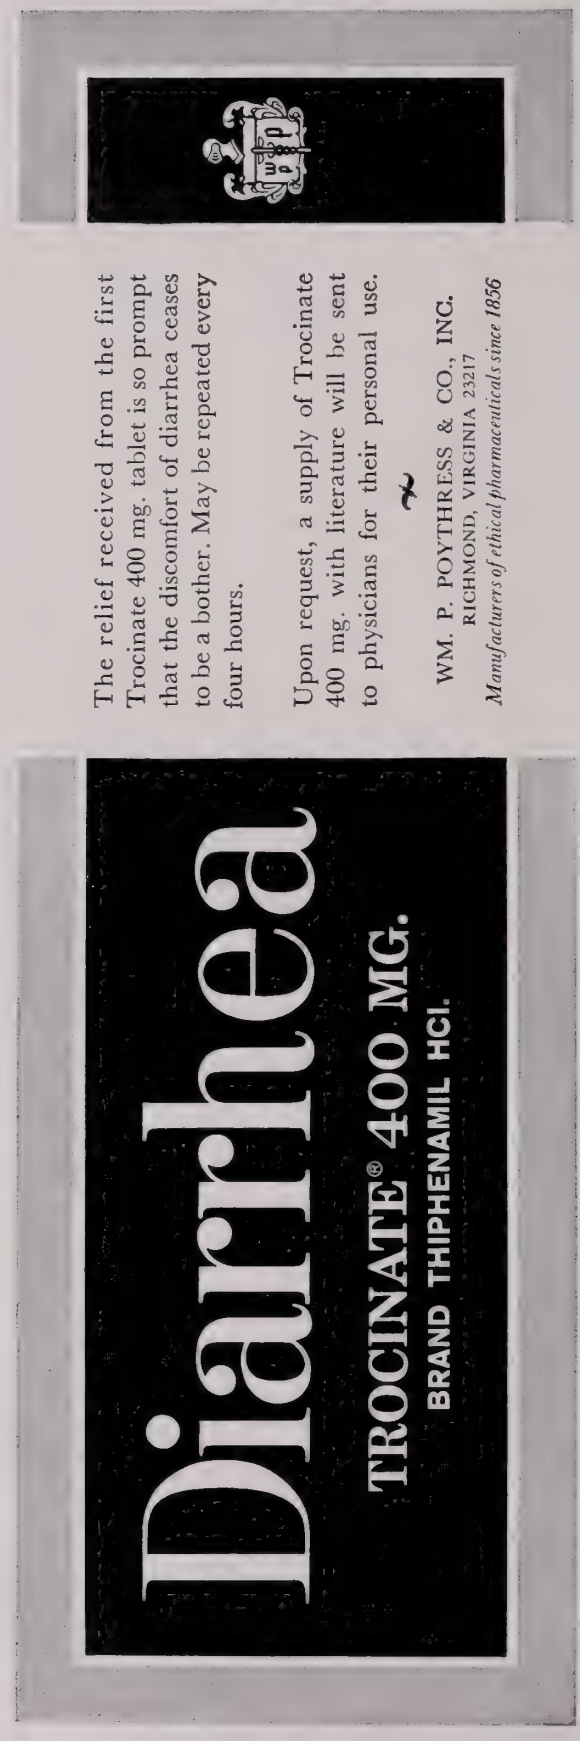
GYNECOLOGIC PATHOLOGY — Frederick T. Kraus, 504 pages, The C. V. Mosby Company: St. Louis, $18.50, 1967.

Dr. Kraus, Associate Pathologist at St. Lukes Hospital in St. Louis and Instructor in Pathology at Washington University School in Medicine, has assembled a sound book. He systematically covers his subject, illustrates lesions with excellent drawings and photographs, and adds an extensive list of recent references.

Although this volume has the credentials of a good textbook, I have reservations about it. It adds little, for instance, to such books as *Novak's Gynecological and Obstetrical Pathology.* Also I find the prose a little wooden. The author plods down well-worn paths, uses the standard descriptive approaches, and writes with carefully hedged long sentences in the passive voice. Though the style is stereotyped, I cannot quibble with the substance. The facts are there, and they are well-organized, clear, and correct.

Richard L. Reece, M.D.
Minneapolis, Minnesota

WILBUR J. COHEN: The Pursuit of Power—Marjorie Shearon. Shearon Legislative Service, Chevy Chase, Maryland, 240 pages, $4.50.



This is an almost incredible account of political chicanery. If I had not read "Mein Kampf" and lived through World War II, I would find a very wide "credibility gap" between myself and Mrs. Shearon. As it is, I am inclined to believe most of what she has set forth in such great detail, not because I am a physician supporting most of the A.M.A. policies, or of the same political persuasion as Mrs. Shearon, but because she has developed this story of intrigue in such a careful manner.

It would be sheer folly for anyone to put into print the accusations and insinuations which she has presented in her charges not only against Wilbur J. Cohen, the main villain in her book, but against many others who are still on the living, breathing list. She talks at some length about the White House Conference on Aging, held in January, 1961. As a member of Governor Anderson's State Council on Aging, I happened to be invited to attend a follow-up of this conference.

Three of us, two staunch Democrats and myself, attended this meeting, where I had the privilege of attending several workshops with a man who was to become one of the best known physicians in these United States, Dr. Edward Annis of Miami, Florida. I give this personal background because I want to say that my own experiences at this meeting make her tale very credible. It was one of those "stacked" meetings, but not so much so that the collective physicians' voices could not be heard. We succeeded in "torpedoing" this meeting, as far as the HEW people were concerned, because we insisted that the truth be told about the subjects under discussion!

THE PURSUIT OF POWER is not as exciting a book to read as WITNESS, by Whittaker Chambers, but comes close and should be MUST reading for every American who is worried about the future of this country of ours. If you aren't concerned before you read this book, you will be afterwards; because the time Mrs. Shearon talks about is NOW!

PHYSICIAN WANTED: G.P. with additional surgical and OB experience—desired to associate with two G.P.'s with similar experience in large, well established practice in Central Minnesota. Hospital accredited, 300 bed, open staff, complete services. Salary leading to partnership. Adequate housing in area. Send background information, professional and personal to: Dr. Goehrs, 825 First Street North, St. Cloud.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

TWO MAN PARTNERSHIP desires a third in general practice. Good office set-up in growing industrial town of 15,000 in Southern Minnesota. Excellent hospital, school systems and recreational facilities. One hour on freeway to downtown Minneapolis. Contact: Drs. Floersch & McEnaney, 127 West Vine Street, Owatonna, Minnesota 55060.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

WANTED: YOUNG PHYSICIAN for association leading to partnership with four well-established General Practitioners in fast-growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Contact: A. Eugene Muller, M.D., North St. Paul Medical Center, 2579 East 7th Avenue, North St. Paul, Minnesota 55109.

GENERAL PRACTITIONER wanted to join well established practitioner in city of 5-6,000 and serving a population area of 18-20,000. Approximately 75 miles west of Mpls.-St. Paul. Well-kept clinic building two blocks from the hospital. Fully accredited 80 bed hospital with a resident Pathologist, Radiological Service, LPN School, X-ray Technician School, and complete Physiotherapy Department. Short-term association on salary basis or long-term association with eventual partnership, will accept, consider and appreciate either terms. Please send short resume of your education and previous experience. For further information about this opportunity write: Gregory M. Olson, M.D., Litchfield, Minnesota 55355.

WANTED—YOUNG INTERNIST. Board certified or eligible, to join 8-man group consisting of 6 GP's, a general surgeon, and a radiologist; college town of 5500 only 30 miles from Twin Cities; salary negotiable with early partnership opportunity. Write or call collect: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisconsin, phone 425-5322.

PSYCHIATRISTS, PEDIATRICIANS, internists, physicians—join staff of treatment facility for retarded children and adults located 45 miles from Minneapolis-St. Paul area. Contact: E. J. Engberg, M.D., Superintendent, Faribault State Hospital, Faribault, Minnesota 55021.

GENERALIST as member of Medical Staff of progressive State Hospital in Michigan's vacationland. Hospital has 3-year accreditation, JCAH and 3-year residency accreditation by A.P.A. Salary $16,000 to $19,800. Excellent fringe benefits. Civil Service security when qualified. Apply L. B. Young, M.D., Director of Medical Services, Traverse City State Hospital, Traverse City, Michigan 49684.

DENTIST INTERESTED IN BUILDING MEDICAL BUILDING in Plymouth Village on Highway 55, west of Golden Valley. Rapidly growing community with no present M.D. in area. Anyone interested in partnership contact: Dr. James H. Hunder, 11335B Highway 55, Minneapolis 55427.

PHYSICIAN interested in internal medicine wanted for medical service. Starting salary $13,507 to $18,481, depending on qualifications. Liberal fringe benefits. An equal opportunity employer. Contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa 50308.

MADDOCK needs a General Practitioner or preferably two, to take over a well-established practice. Present physician leaving for Philippines in the Spring. Progressive community, large area, modern 22-bed hospital, separate clinic, new school under construction. If financial independence, a real desire to help our people and becoming one of us interests you, contact Donna Rice, Memorial Hospital, Maddock, North Dakota.

FOR SALE: Modern clinic building 44 x 80, brick and block construction. Seven years old, adequate examination, emergency treatment and X-ray rooms, plus private offices, and laboratory rooms. Fully air conditioned. Located in West Central Minnesota, City of Approximately 5000 population. Write: MINNESOTA MEDICINE-392, 375 Jackson St., St. Paul 55101.

PEDIATRICIAN—to join established department of pediatrics in 17-man mid-western group. Excellent opportunity in a growing-dynamic clinic with early partnership. Town of 33,000 with two hospitals and excellent schools. Clinic staff enjoys regular vacations and time off for study. Write: MINNESOTA MEDICINE-393, 375 Jackson St., St. Paul 55101

PHYSICIAN INTERESTED IN PURCHASING PRACTICE IN THE TWIN CITIES AREA. Write: MINNESOTA MEDICINE-394, 375 Jackson St., St. Paul 55101.

WANTED: LOCUM TENENS for general practice for July or August, 1968. Salary open. Location within one hour's driving from Twin Cities. Write: MINNESOTA MEDICINE-395, 375 Jackson St., St. Paul 55101.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

b.i.d.

The sensible schedule that covers the patient day and night

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, then you know why b.i.d. DECLOMYCIN is considered to be a sensible dosage schedule.

The maintenance dosage of DECLOMYCIN can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

The b.i.d. dosage of DECLOMYCIN gives you the comfortable assurance that the patient is well-covered, *day and night.*

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective; because of high serum binding and slow renal clearance. And if there's a broader susceptibility pattern of organisms, we've yet to see it.

There is no need to give higher daily dosage than 300 mg b.i.d., except in venereal diseases and Eaton Agent pneumonia.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Lederle

Prescribing information on next page.

b.i.d. The sensible schedule that covers the patient day and night

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occure. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes. A rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth— dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm. given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.

Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg. of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg. every 6 hours for a minimum of 4 doses or 300 mg. every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg. every 6 hours or 300 mg. every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg. in 3 divided doses for six days.

Analysis of Appendectomies in Duluth

ROBERT J. CAMPAIGNE, M.D.*
Duluth, Minnesota

SINCE THE CLINICIAN Reginald Fitz of Boston coined the term appendicitis in 1886[1] and appendicitis was listed on the vital statistics as a cause of death in 1892,[2] the disease entity has reached paramount importance as a diagnostic probability. The inflamed appendix remains one of the chief causes of the acute abdomen requiring surgery, in spite of its seemingly decreasing incidence as related by Ross[3] and Castleton.[4] This decline has not, however, been noted in England.[5] At present the overall mortality in the United States is 12 per 1,000,000.

Method

A statistical analysis of all appendectomies was compiled in Duluth over a ten-year period 1956 through 1965 from the individual case records of the two general hospitals, St. Luke's and St. Mary's. In this period 4127 appendectomies were performed, divided into three main categories: 1) acute appendectomies, including the normal and simple variety and those with local and general peritonitis; 2) interval appendectomies; and 3) incidental appendectomies of three varieties: pelvic surgery, cholecystectomy, and "other surgery" (Table 1).

Findings in the Appendix

The Inflamed Appendix

The inflamed appendix includes the simple variety, that with local peritonitis such as abscess, etc., and that with general peritonitis: a total of 2046 cases. Pathologically the inflamed appendix is the simple, acute, catarrhal, gangrenous type; periappendicitis; and suppurative varieties with or without an obstructive factor. There were 234 cases of local and general peritonitis, or 12.9% of the acutely inflamed. Hence it would appear that one in eight individuals with acute appendicitis at the time of surgery presents with an advanced form of the disease process, a rather consistent observation conforming nicely with Barnes' study at Massachusetts General Hospital in which the perforated case appears in one out of six appendectomies performed for acute symptoms.

Pathologically there were 290 normal appendices in this series out of 2336 acute cases, representing a 12.4% error in the diagnosis, well within the range of probability when considering the numerous etiologies of the acute abdomen. Further, Howie[6] in Scotland and Elfving[7] in Finland have demonstrated that the mortality in removing a normal appendix is only one in 5,000, compared to a mortality of one in 850 in the same type of patient with acute appendicitis treated medically.

b. Cholecystectomy	696	
c. Other	252	
Grand Total		4127

*West Duluth Clinic, Duluth, Minnesota.

The patient with a normal appendix pathologically, who has symptoms of an acute abdomen, is always an enigma, especially if an adolescent. A whole host of pathological processes come to mind. For example, a fecalith may cause appendiceal obstruction and colic with clinical signs of appendicitis; but microscopic examination of the delivered appendix is often found to be normal. Similarly the appendix with oxyuriasis or the long tenuous abdominal appendix with kinking and subsequent obstruction may produce acute symptoms without inflammatory changes. Hence one can justify the removal of an occasional normal appendix in a doubtful case.

Interval Appendectomy

Only 84 cases (5.4%) of the acute appendices were removed as an interval procedure. This procedure is declining annually at approximately 1% per year, suggesting its decreasing necessity with better surgical judgment and care.

Incidental Appendectomy

The incidental appendectomy is always interesting, for the probability of developing acute appendicitis varies with age and sex, males slightly outnumbering females. Ludbrook[8] has demonstrated in New Zealand a probability of 13 in 100 of the general population developing an acute appendix before the age of five years, with a 0.5 in 100 probability at the age of 80, the incidence declining rapidly after the age of twenty. Hence it would seem logical to remove the appendix electively in a younger individual whenever possible. In this series 85.1% of the total 1707 cases of incidental appendectomies were performed with pelvic and gallbladder surgery. Inasmuch as the average age in this group of patients varies between 40 to 50 years, one may postulate that removing the appendix is unnecessary in the vast majority of adults on an incidental and statistical basis.

Wound Infection

Of those 2336 patients operated upon for acute symptoms, 179 (7.2%) developed wound infections. The infection rate was higher in those with peritonitis and in the older patients. In addition, there were eight cases of pelvic abscess and one case of gross peritonitis postoperatively. Barnes[9] has demonstrated that the wound infection rate is variable, with a 1.7% incidence in the "normal", 3.5% in the acute, and 24% in the perforated appendix.

Mortality

The postoperative mortality of the acute appendix in this series was 0.43% (10 cases), comparing favorably with other series. Four patients died of vascular causes, pulmonary emboli phenomena and acute myocardial infarction; three expired from overwhelming sepsis, two from the complications of diabetes mellitus, and one patient from septicemia.

Associated Problems with Acute Appendicitis

Pregnancy

It is often stated that appendicitis is a rare finding in pregnancy. In this series, twelve cases occurred in pregnancy (an incidence of 0.6%), comparable to that found in other series.[10]

Malignancy

Since occult malignancies of the left colon are said to be present in 1 to 3% of patients with acute appendicitis over the age of 60, the acute appendix serves as a "warning" signal in the partially obstructing colonic lesion. In this review three such cases were found. Hence it would be advisable to obtain colon x-rays in the elderly patient within a reasonable time after appendectomy for acute symptoms.

The Surgeon

In determining the surgeon in appendec-

Mucocele	1	
	2046	100%

tomies for acute symptoms, it was observed that the family physician performed 1170 (50.1%), the Duluth Clinic surgeons 361 (15.5%), and the independent surgeon 805 (34.4%).

Etiology

The pathology of acute appendicitis can be observed in Table 2. Fecaliths were observed in only one out of five cases of acute appendicitis.

The adenocarcinoma and carcinoid were limited to the appendix without signs of metastasis. The one case of mucocele was also limited to the appendix, though it may be malignant in nature, as reported by Behling.[11]

Variation in Acute Appendix

Decreasing Incidence

The decreasing incidence of acute appendicitis observed by Ross & Castleton was based on the analysis of local populations and the absolute number of appendectomies performed in the local hospital. It may well be that the declining incidence is secondary to an increasing longevity of the population, making for a relative rather than an absolute decrease. In this small series (Chart 1) there is little variation from year to year. The annual overall average of appendicitis in Duluth is roughly 2 in 1,000, somewhat less than the overall national average.

Age and Sex Distribution

Since 55.0% of the male and 60.3% of the female cases are in the age group 0 to 20 years, one can see that acute appendicitis is primarily an adolescent disease process, male and female duplicating each other statistically, except that the males outnumber the females by approximately 1½ to 1 up to the age of 50 years and 2 to 1 thereafter (Chart 2).

Seasonal Variation in Acute Appendix

Much has been said as to the seasonal variation of the acute appendix. Chart 3 shows that there was a peak of 209 cases in the month of June, the male and female cases 119 and 90, respectively.

Although the least number of appendices were removed in September, the variations are

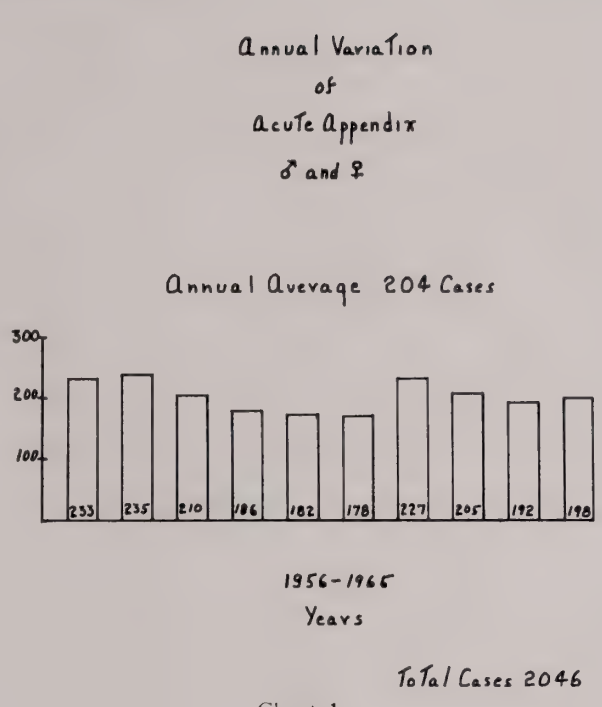

Chart 1

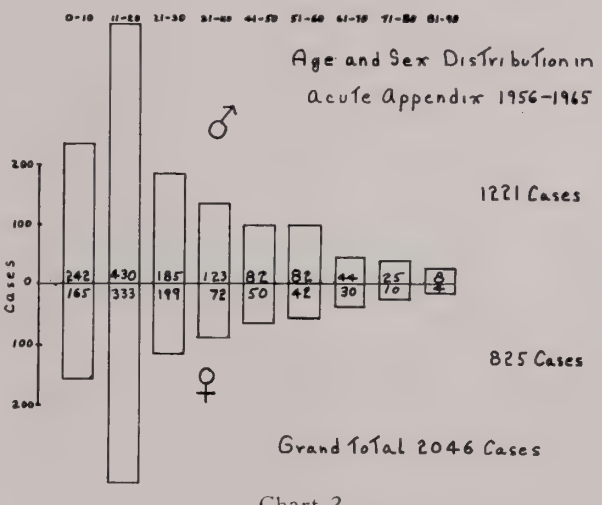

Chart 2

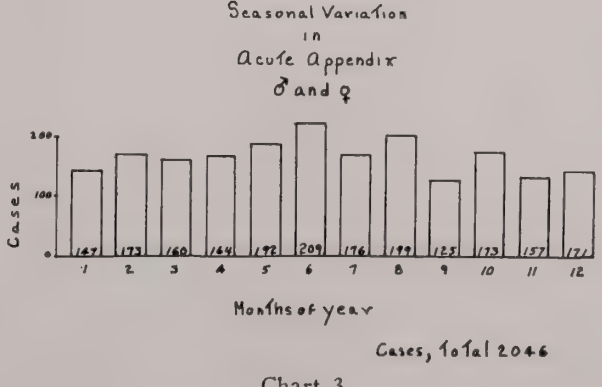

Chart 3

not statistically significant but rather a "barometer" of an increase in acute appendicitis in the late spring and summer months as observed in Chart 4.

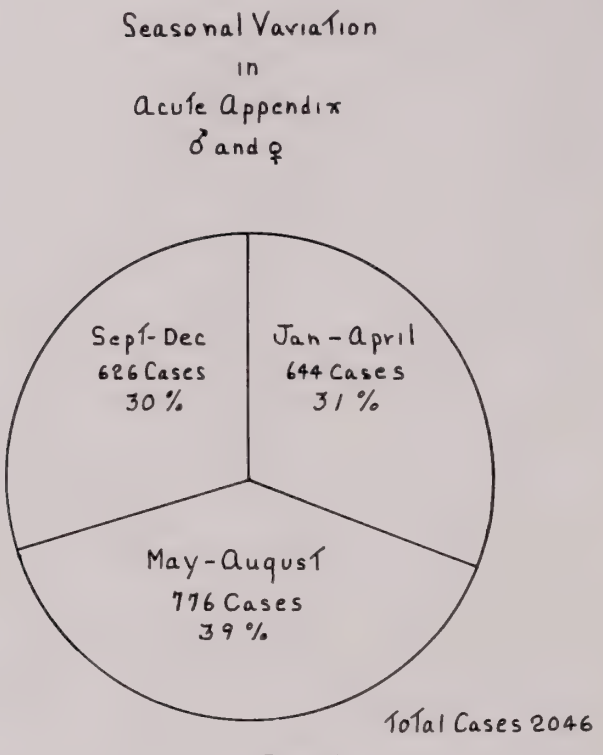

Chart 4

Summary and Conclusions

The incidence of the inflamed appendix in this series was a consistent 2 in 1000 in the general population.

The operative mortality of the acute appendix was .46%, comparing favorably with other series.

Acute appendicitis in pregnancy had an incidence of .6%.

A fecalith was found in the acute appendix in only 18.9% of the cases.

The inflamed appendix is predominantly an adolescent disease, with the majority of cases occurring at 20 years of age, the males outnumbering the females by 1½ to 1.

It would appear that acute cases predominate in the late spring and summer months.

Acknowledgment

I wish to thank the personnel of the Medical Records Departments in St. Luke's and St. Mary's for their help and cooperation in compiling the statistics for this research paper. I also wish to thank Dr. John V. Thomas for his assistance.

Correction

MINNESOTA MEDICINE carried an article under Law and Medicine on the Minnesota Hospitalization and Commitment Act, and I would like to correct one error which appeared on Page 1418 in connection with the Review Board. In the article it states that the members of the Review Board would receive $30 per day as compensation. Actually, the law allows $50 as compensation and represents the true amount as stated in the law, and we would like your readers to be aware of this.

David J. Vail, M.D.
Medical Director
Department of Public Welfare

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

This article initiates a new regular feature in Minnesota Medicine, designed to help keep you informed about *your* regional medical program.

What is a Regional Medical Program (RMP)?

The law (#89-239) defined the purposes of RMP as follows:

"(a) To encourage and assist in the establishment of regional cooperative arrangements among medical schools, research institutions and hospitals, for research and training (including continuing education) and for related demonstrations of patient care in the fields of heart disease, cancer, stroke and related diseases;

(b) To afford to the medical profession and the medical institutions of the Nation, through such cooperative arrangements, the opportunity of making available to their patients the latest advances in the diagnosis and treatment of these diseases, and

(c) By these means, to improve generally the health, manpower and facilities available to the Nation, and to accomplish these ends without interfering with the patterns, or the methods of financing of patient care or professional practice, or with the administration of hospitals, and in cooperation with practicing physicians, medical center officials, hospital administrators, and representatives from appropriate voluntary health agencies."

Who Organized the Minnesota Program?

The key to RMP is cooperative arrangements. In Minnesota, nine organizations cooperatively developed Northlands Regional Medical Program—Minnesota State Medical Association, Minnesota Hospital Association, University of Minnesota College of Medical Sciences, Mayo Foundation, Minnesota State Board of Health, Minnesota Heart Association, Minnesota Cancer Society, American Rehabilitation Foundation, and Minnesota State Medical Association Foundation.

What is the Objective of the Program?

The focus is on the patient. Each region is asked to define its geographic boundaries, identify its needs, outline its objectives and develop programs whereby each patient can receive the benefits of the latest scientific knowledge.

What are the Problems?

Each of you has problems in the practice of medicine such as: How can I find practical information on the latest diagnostic and treatment methods for x, y and z diseases? Where can I get the reliable laboratory and other diagnostic tests which I need? How can I get necessary consultations? How do I get hospitals and necessary paramedical disciplines to take over an increasing share of medically related responsibilities? How do I get some help for the stupendous work-load?

There are plenty of additional problems—it is certain that each of you could contribute a dozen more.

Northlands Regional Medical Program is a federally supported venture to help Minnesotans solve their problems of delivery of medical care services, to the end that each patient may have the benefits of the latest in modern medical knowledge. The challenge is great—we hope the willingness to cooperate can be stimulated in the Medical Centers and among the practicing profession.

Addendum

The philosophy ably expressed by Dr. Ciriacy* in "President's Letter" last month is closely analogous to the philosophy of Northlands Regional Medical Program. Can we all work together to distill the "Ferment in Medicine" in Minnesota? As expressed by John W. Gardner on educational television, we need "grass roots leadership" to counteract the adverse effects of "sophisticated dropouts" and "sidewalk superintendents."

Winston R. Miller, M.D., F.A.C.P.
Program Director

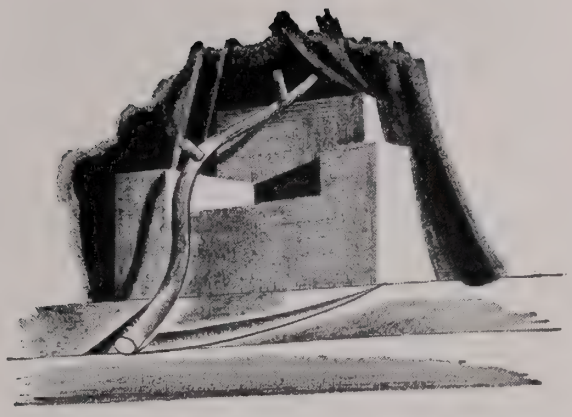
The Unsureness of Science



Let no man be so foolish as to think that he has exhausted any subject for his generation. Virchow was not happy when he saw the young man pour into the old bottles of cellular pathology the new wine of bacteriology. Lister could never understand how aseptic surgery arose out of his work. Ehrlich would not recognize his epoch-making views on immunity when this generation has finished with them. I believe it was Hegel who said that progress is a series of negations—a denial today of what was accepted yesterday, the contradiction by each generation of some part, at least, of the philosophy of the last; but all is not lost, the germ plasm remains, a nucleus of truth to be fertilized by men, often ignorant even of the body from which it has come. Knowledge grows, but in such a way that its possessors are never in sure possession. "It is because science is sure of nothing that it is always advancing." (Duclaux)*

In Memoriam

That last day does not bring extinction to us, but change of place.—Cicero

We begin to die as soon as we are born, and the end is linked to the beginning.—Manilius

MARIO McC. FISCHER, M.D.

Dr. Mario McC. Fischer, 68, executive health officer of St. Louis County until his retirement last July, died January 15. A native of Minneapolis, Dr. Fischer had practiced in Duluth since 1926.

He was a member of the Minnesota Public Health Conference, the American Public Health Association, the American Medical Association, and the St. Louis County Medical Society. He was an associate member of the Minnesota State Medical Association. Dr. Fischer served as president of the National Tuberculosis Association, as director of the Tuberculosis and Health Association of St. Louis County, the Duluth Mental Hygiene Association, the Duluth Chapter of the Minnesota Cancer Society and the South St. Louis County Chapter of the National Foundation.

Dr. Fischer was the recipient of the Minnesota Public Health Association's Chesley Award, the group's highest award.

He is survived by his wife and two sons.

WILLIAM A. KLEIN, M.D.

Dr. William A. Klein, 59, Duluth orthopedic surgeon, died January 16. He had practiced medicine in Duluth since 1946. Born in St. Peter, he received his medical degree at the University of Minnesota.

Dr. Klein was a member of the St. Louis County Medical Society, the American Board of Orthopedic Surgeons and the American Medical Association and an associate member of the Minnesota State Medical Association.

He is survived by his wife, two daughters and a son.

PETER C. ENGELHART, M.D.

Dr. Peter C. Engelhart, 71 Minneapolis physician, died December 30. Born in Mazeppa, Minnesota, Dr. Engelhart received his medical education at the University of Minnesota.

He was a member of the American Medical Association and the Hennepin County Medical Society and an associate member of the Minnesota State Medical Association.

He is survived by his wife and two children.

RAUEN A. CURTIS, M.D.

Dr. Rauen Curtis, 60, Le Center physician, died November 6. Born in Osseo, Dr. Curtis obtained his medical degree from the University of Minnesota Medical School.

He was a member of the American Medical Association, Nicollet-LeSueur County Medical Society and the Minnesota State Medical Association.

He is survived by his wife.

MORSE J. SHAPIRO, M.D.

Dr. Morse J. Shapiro, former clinical director of pediatrics and medicine at the University of Minnesota Medical School who helped establish the Variety Club Heart Hospital in Minneapolis, died February 11, in West Los Angeles, California. He was 74 years of age. In 1951 he moved to California when he became chief of pediatric cardiology at Cedars of Lebanon Hospital.

He established and directed a clinic in Minneapolis for children who were victims of rheumatic fever, which gave impetus to the building of the Variety Club Heart Hospital. In 1955 he received the University's first special commendation for distinguished achievement as a pioneer in scientific knowledge in the heart field.

He is survived by his wife, a daughter and a son, Dr. Marvin Shapiro of Sherman Oaks, California.

Help America get ahead

Adopt a college

It costs less than you'd suppose to buy a share in America's future leadership.

In fact, what you give will be of immeasurable help to our colleges and universities today.

Enrollments are growing fast. Facilities must be expanded, new teaching talent attracted. (Faculty salaries are up 6.8% this year alone.)

We can't settle for second-rate education. Not if America is to remain first.

Your support can well mean the difference to your children's future—and the nation's.

Give to the college of your choice. (If you haven't a college of your own, it's easv enough to adopt one.)

Published as a public service in cooperation with The Advertising Council and The Council for Financial Aid to Education.

Social Security

Retirement Benefits for Physicians under Social Security

SELF-EMPLOYED DOCTORS have been paying the Social Security tax on their net earnings for three years and therefore in 1968 physicians who have attained the age of 70 are now eligible to receive Social Security payments if their net earnings do not exceed $1,680 per year.

To be retired for Social Security purposes means either that the doctor's yearly net income is limited to $1,680 or he does not perform a substantial amount of service in one or more months in the year. If this 70-year-old physician takes a vacation or becomes ill for one or more calendar months and does not work at his practice, he is considered retired for that month and can receive Social Security benefits of $157.80 (see Table).

After a physician's seventy-second birthday there are no restrictions on the earnings, and he is eligible to obtain Social Security benefits regardless of the earnings from his practice. If he continues to earn $6,600 or more, his Social Security benefits can increase from year to year as indicated in the Table.

The doctor (and wife) who has been on a salary for many years, now age 65, can retire in 1968 with Social Security benefits of $238.20 per month. If he does not retire, however, his Social Security benefits will continue to increase from year to year. The maximum increase in Social Security benefits for doctor and wife may reach $323.00 per month (see Table).

It must be remembered, however, that circumstances are variable in almost every instance, and for an accurate evaluation of your own Social Security status it is advisable to call the Social Security Administration District Office.

TABLE
SELF-EMPLOYED SOCIAL SECURITY BENEFITS
FOR PHYSICIANS

Age in 1968	Dr. & Wife February 1968	Dr. & Wife January 1969	Dr. & Wife January 1970	Dr. & Wife January 1971	Dr. & Wife January 1972	Dr. & Wife January 1973	Dr. & Wife January 1974	Dr. & Wife January 1975	Dr. & Wife January 1976

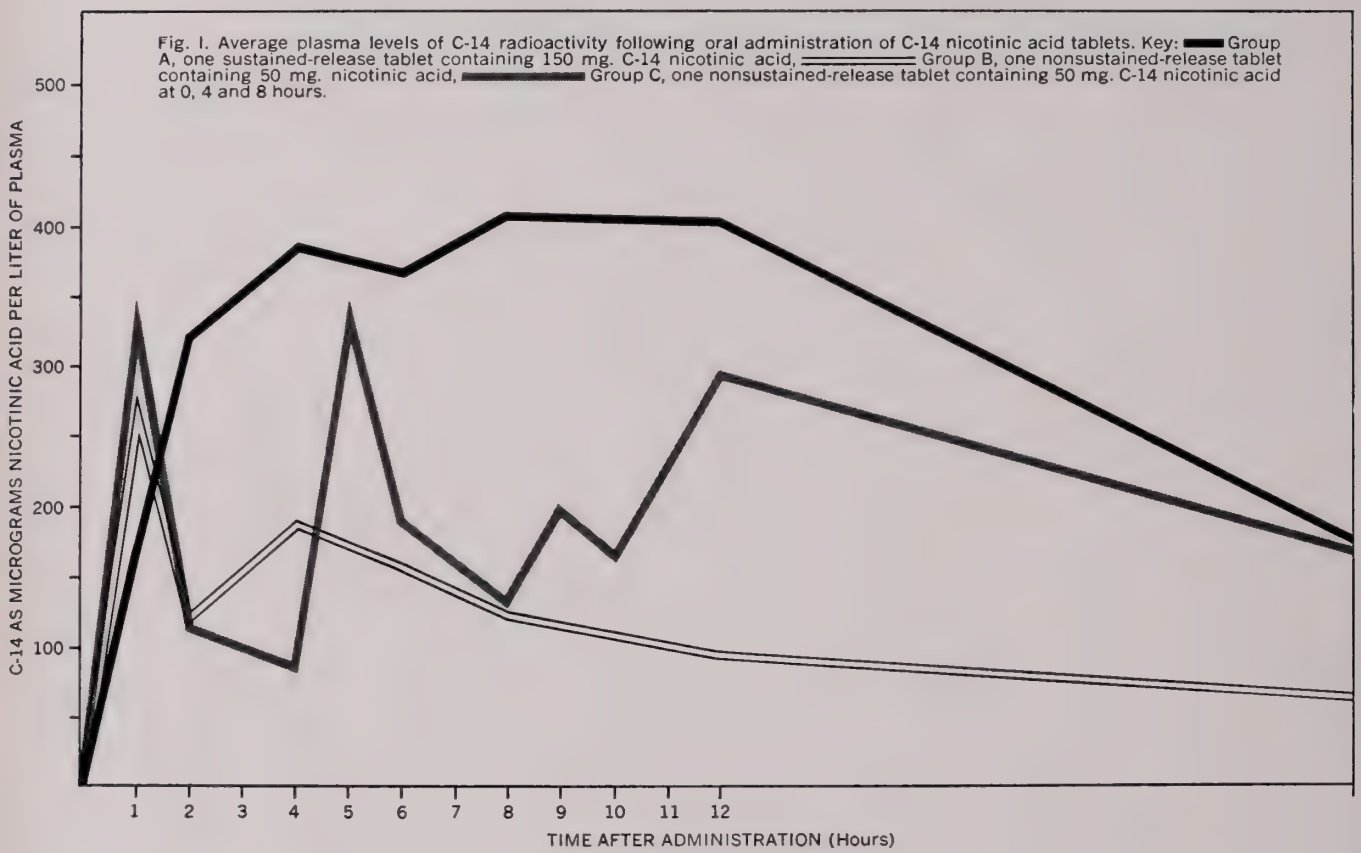
(one tablet daily)

Regroton®

chlorthalidone 50 mg., reserpine 0.25 mg.



Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Regroton should be used in pregnant patients or in women of childbearing potential only when, in the judgment of a physician, its use is deemed essential to the welfare of the patients; adverse reactions (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.
Precautions: Antihypertensive therapy with Regroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue Regroton therapy two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, Regroton should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000. (B) 46-600-B

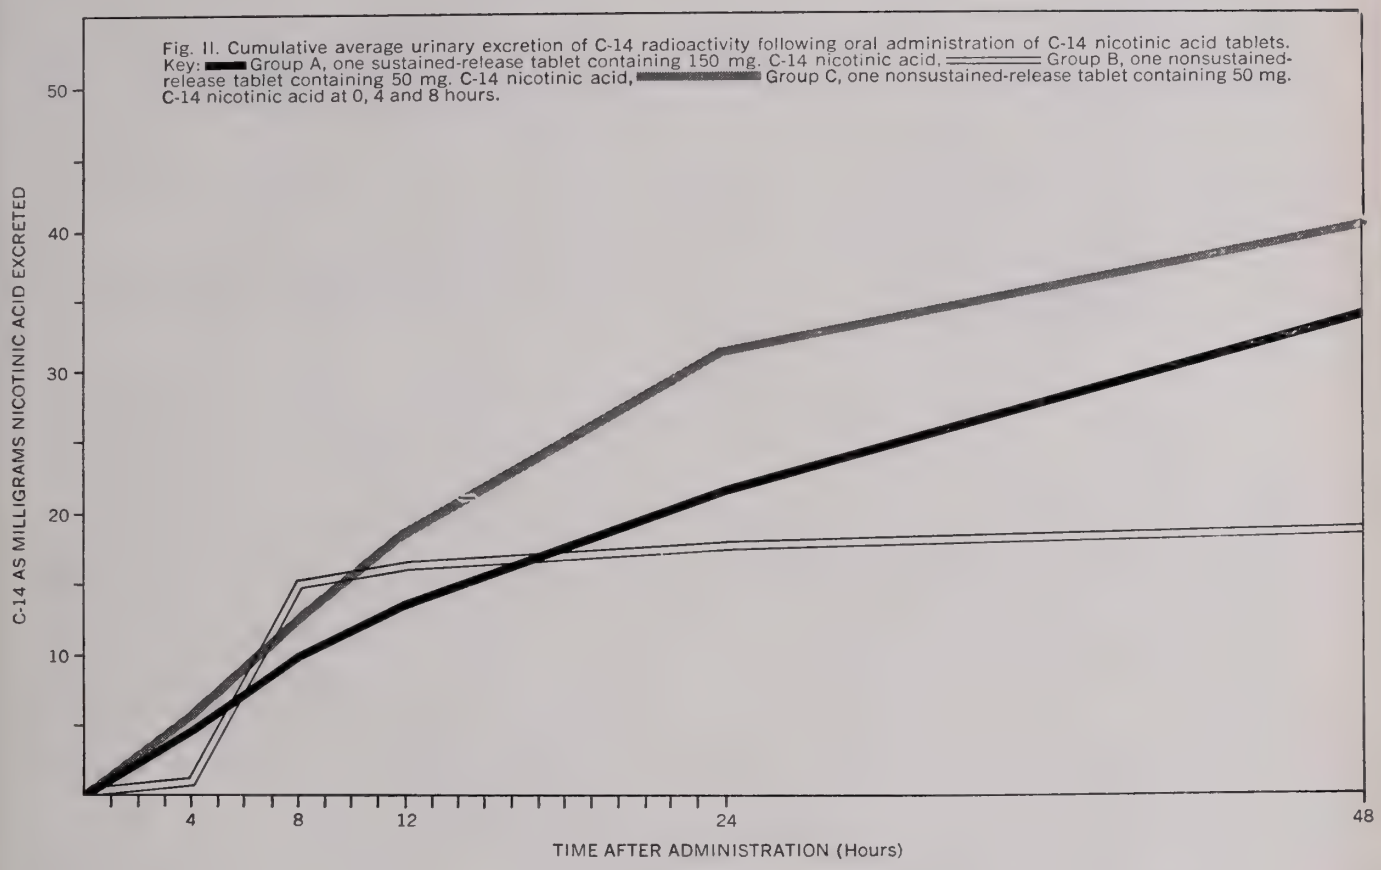
Sustained circulatory, respiratory and cerebral stimulation for the

Fig. I. Average plasma levels of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: ▬ Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, ═══ Group B, one nonsustained-release tablet containing 50 mg. nicotinic acid, ▬▬ Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

(fewer absent doses by absent-minded patients)



Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

North Memorial Hospital auditorium, April 7, 1968. Afternoon and evening sessions (1:15 p.m. to 8:45 p.m.), with dinner being served at 5:30 in the hospital dining room. Attendance has been approved by the Academy of General Practice for 6 hours of Post-Graduate Study. Since the number of registrants will be limited, they will be accepted by acknowledgment in the order received. Contact Ralph Rossen, M.D., 588-0616, extension 301, or 339-1692, extension 596.

Minnesota Medicine at a Glance

Reye's Syndrome—Mack Page 335

Rare diseases continue to be rare as long as physicians are content to misfile problems under old disease categories. They are not so rare when the unsatisfied observer works out the problem. This article contains the 128th reported case of a child with encephalopathy and fatty degeneration of the viscera. That this usually fatal disease may be much more common in a non-fatal form is suggested by the tendency to recovery observed in the child before unexpected and unanticipatable complications of drug idiosyncrasy caused his death.

Coronary Arteriography—Lee and Amplatz Page 343

Selective coronary arteriography is the radiographic method of choice in evaluating coronary artery anatomy and pathology. Attempts of non-selective coronary arteriography frequently result in poor opacification of one or more major coronary branches. Inadequate visualization and poor opacification may lead to erroneous diagnoses. In addition, selective coronary arteriography can provide information such as inter-coronary anastomoses or coronary arteriovenous fistulae that are difficult to demonstrate by non-selective aortography. The risk of selective and non-selective coronary arteriography in our experience is identical.

Upper Lip Nodules—Erich and Jamra Page 347

A review of nodules in the upper lip of patients treated at the Mayo Clinic from 1944-1963 is presented. Eighty-six percent were neoplasms and the importance of adequate treatment is stressed.

My Grandfather Made Me Wish to Become a Doctor

Probably I should never have known that the Boston Lying-in Hospital existed, nor indeed should I ever have studied medicine, had not my maternal grandfather, when I was a small boy, unknowingly and unintentionally made me wish to become a doctor.

As Assistant Surgeon in the Thirty-Fifth New York Infantry my grandfather had joined the Union Army soon after the outbreak of the Civil War. His story of the bloody aftermath of conflict, of his work among the maimed and dying, was strong meat for a boy of ten; but its sole effect on me was to sharpen my appetite for more.

The relationship between my grandfather and myself was of a particular and private nature. When he talked to me it was always as if I were of his own age; there was no painful simplicity of words, no tedious explanations. If he had known that I wished to become a doctor, I am sure he would have been displeased, for his life had been a hard one, and it would have pained him to picture a similar experience for me; so I kept my counsel.*

Editor's Note: *Frederick Irving served in World War I and later became consulting obstetrician to the Boston Lying-in Hospital.*

Dilantin®
(diphenylhydantoin)

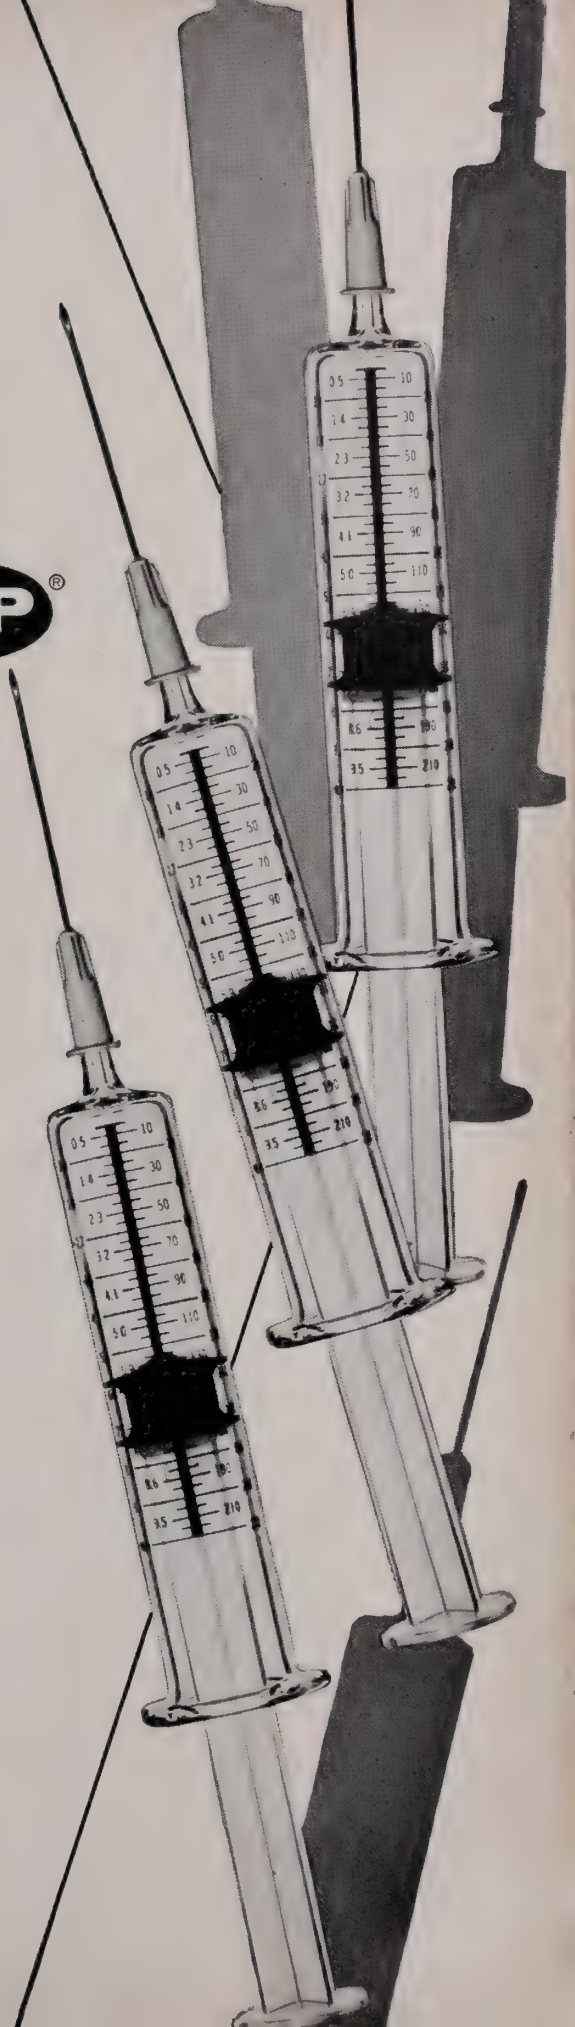
PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anticonvulsant drugs.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. ADVERSE REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred.
DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.
Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS 01SR67



BSP® DISPOSABLE UNIT

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

(50 mg. per ml.)

BSP®

BROMSULPHALEIN®

IN A COMPLETE,

STERILE,

DISPOSABLE,

& ECONOMICAL

PATIENT-UNIT.

BSP, one of the more valuable single laboratory procedures for determining hepatic function, is now packaged in a complete individual patient-unit.

Each BSP Disposable Unit contains a sterile syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of terminally sterilized Bromsulphalein solution.

This all-inclusive disposable put-up lessens the chance of cross-infection and saves time and labor— the most costly commodities.

BALTIMORE, MARYLAND 21201

SAN FRAN CISCO AMA '68

The excitement of San Francisco's famous sites is waiting for you. Chinatown, the Golden Gate Bridge, Fisherman's Wharf, Telegraph Hill, will add to five memorable and stimulating convention days. Plan to attend now and look forward to an excellent convention in a city of unlimited charm.

Continue your postgraduate education with a varied program of • four General Scientific Meetings on Auto Accidents, Health Care Planning, Infectious Diseases, Treatment of Advanced Malignant Disease • 23 Section Programs • Color Television • Medical Motion Pictures • and over 600 scientific and industrial exhibits. All are designed to bring you up-to-date on what is making medical news today. You will attend lectures by the nation's outstanding medical authorities and discuss with them the significant advances in medicine.

In addition the AMA TV network will present more than 40 hours of convention news.

Reserve now for the Scientific Awards Dinner in honor of the Scientific Award Winners—Wednesday, June 19, 1968. Since space is limited, we suggest you make your reservations before June 3, 1968. Tickets are $10.00 each, payable in advance.

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, May 6, 1968.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to Minnesota Medicine, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in Minnesota Medicine. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

President's Letter

Quality Care-Concerned Care

WHEN ELECTED by my colleagues in the Minnesota Society of Internal Medicine I felt very much honored. Now, being expected to provide some written thoughts worthy of the time and the attention of the readers of this Journal, finds me anxious to do just that. My anxiety mounts as I consider the best way to discuss the subject I feel needs some emphasis. The emphasis is general and not aimed at any specific group because the subject is not group-specific.

With increasing government-sponsored medical care and increasing amounts of "third-party" participation in the financial aspect of medicine, doctors of medicine of whatever persuasion, specialty, or organization have become increasingly apprehensive that these "outside" forces might in some way result in an inferior quality of medical care. At least this apprehension has been the "sacred cow" on which much of our organized objection to these programs has been based, and perhaps rightly so. At any rate, there has been considerable scurrying about on the part of medical organizations to "establish our perimeters"—set up standards or criteria which would clarify the various types of medical or surgical care, and thereby also establish commensurate fee schedules. We now have "relative-value" schedules which help delineate certain types of medical care and their attendant financial remuneration, but really no guarantee of a higher quality of medical care.

We also now have Medicare, full-fledged and apparently burgeoning, with perhaps new election-year expansions ahead. We have had some problems in the mechanics of operation of the programs, but from my vantage point I do not see any increased evidence of deteriorated medical care. We still have the human errors of judgment, miscalculation, and carelessness; even some of the former evidence, unfortunately, of frankly false medical care, but no great upsurge. Perhaps we can credit some of this upholding of quality to the very measures organized medicine has been able to include in the legislative programs. But I prefer to give credit in another direction.

From my day-to-day experience I judge my colleagues to be continuing to give their best to the care of their patients, and I also observe this in the majority of the young men in training with whom I have come in contact. As I try to explain this continuing attempt to render quality medical care, I cannot believe it results mainly from concern for establishing a system for furthering personal gains. Instead of concern for self it arises, I believe, out of concern for the patient. We have, over the years, tended to extol the "doctor-patient relationship" and protect it as a "holy grail." Concern for the patient as a person is to my mind the best means of minimizing those human errors of poor judgment, miscalculation, and carelessness; that concern should totally eliminate frankly false medical care. Surveys which have shown the marked disparity between a layman's high appreciation and approval of a known doctor and the far lower ratings of doctors in general reflect this factor. When one believes his doctor is concerned, he feels he is in better hands than with an indifferent doctor.

We need not reemphasize the importance of top-quality medical facilities, training, and continuing education. But perhaps we can benefit by refocusing on a major determinant of the best medical care—a real concern for the patient; and avoid the blurring of our goal by so many other anxiety-producing factors in our society.

FAMILIAL HYPERCHOLESTEROLEMIA is the most common cause of atherosclerosis in the pediatric age group. Recognition of this disease started with the descriptions of xanthomatous lesions by Rayer[1] in 1826 and by Addison and Gull[2] in 1851; the familial nature of the disturbance was pointed out in the latter part of the nineteenth century.[3-6] Chaufford and LaRoche[7] in 1910 first associated the state of xanthomatosis with hypercholesterolemia in the presence of liver disease; ten years later Burns[8] reported a patient with xanthomata and hypercholesterolemia who was free of liver disease. Arterial involvement as part of the syndrome was known as early as 1872,[9] but a definite correlation in young patients of premature atherosclerosis with familial hypercholesterolemia was well-documented only in the late 1940s and early 1950s in a series of papers by Adlersberg and Boas.[10-12] Genetically, familial hypercholesterolemia is thought to be due to a dominant gene with incomplete penetrance.[13-15]

The occurrence of a true homozygous† (type II) hypercholesterolemic individual is rare indeed, depending as it does on the small chance of conjugation between people carrying the gene for the Fredrickson type II hyperlipidemia,[16] as well as on Mendelian probability. Such unfortunate individuals have, in essence, a "double dose" of the disease, and their rate of development of atherosclerotic cardiovascular manifestations can be expected to be greatly accelerated. The homozygous hypercholesterolemic patient usually presents a unique pattern of findings: the individual is in his teens or younger, arcus senilis is present, subcutaneous and tendon xanthomata are evident, atherosclerotic fundic changes can be seen, and the patient commonly complains of severe exer-

**Established Investigator, American Heart Association. Dr. Buchwald was given the Gross Award by the Philadelphia Academy of Surgery at their annual meeting for his overall approach to this problem.

†See Test Your Word Score Page 511.

tional angina pectoris. An early death from myocardial infarction is to be expected. A characteristic lesion of these patients is acquired aortic valvar stenosis and/or, occasionally, aortic valvar insufficiency,[17,18] both due to heavy accumulations of proliferative atherosclerotic plaques in the valve and adjacent aortic wall. Similar plaques can also involve the orifices of the coronary arteries.

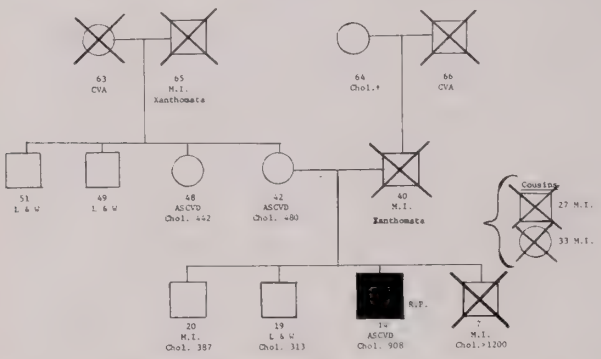

Fig. 1—Diagram of family tree.

Fig. 2—Subcutaneous xanthomatous lesions over the elbows of patient R.P.

Fig. 3—Subcutaneous xanthomatous lesions over the knees of patient R.P.

This case history describes a 14-year-old homozygous hypercholesterolemic boy with far-advanced atherosclerotic coronary heart disease, and reviews our diagnostic and therapeutic approaches to this problem.

Report of a Case

History

R. P. was the product of a normal birth and gestation with both parents having familial xanthomatosis. Massive subcutaneous and tendon xanthomata appeared a few years after birth. At one time, some of these lesions were surgically removed. His cholesterol level has always been around 1000 mg%. This value was maintained despite efforts to keep the boy on a stringent, low-cholesterol, low saturated-fat diet since birth. In addition, he was treated, from time to time, with nicotinic acid and, more recently, with cholestyramine, both without significant effect on his serum cholesterol level. At about the age of nine he developed definite exertional angina pectoris, the severity of which progressed over the years. When we first saw him one year ago he was no longer able to participate in the normal activities for boys of his age. He was essentially limited to a sedentary existence.

Family History

The family history has been traced back to both sets of grandparents and is graphically illustrated in Figure 1. It can be seen that R.P.'s maternal grandparents both died of coronary or cerebral vascular manifestation of atherosclerosis. His paternal grandfather died of a cerebral vascular accident; his paternal grandmother is living, age 63, and has a high serum cholesterol level and xanthomatosis. His father died at the age of 40 of an acute myocardial infarction. The boy's mother is alive, has sustained a cerebral vascular accident, and has coronary angiographic evidence of marked occlusive disease. Her serum cholesterol (prior to an ileal bypass operation) averaged 480 mg% despite dietary management. Her blood cholesterol level was also refractory to nicotinic acid and cholestyramine. R.P.'s siblings consist of two living brothers and one dead brother. The oldest living brother, age 20, had a myocardial infarction 1½ years ago; his serum cholesterol level was 387 mg% prior to a partial ileal bypass operation. He had no angina pectoris before or after his myocardial infarction and has no angiographic evidence of aortic root involvement. The next oldest brother is now 19 and has a serum cholesterol level of 313 mg%; he is completely free, symptomatically and angiographically, of any manifestations of atherosclerotic cardiovascular disease and has no peripheral xanthomatoses. The youngest brother died at the age of

seven, presumably of an acute myocardial infarction while experiencing severe crushing chest pain. His cholesterol level had been over 1200 mg%.

Physical Examination

On admission to the University of Minnesota Hospital, R.P.'s pulse rate was regular at 80 and his blood pressure was recorded at 130/70. Advanced arcus senilis was evident. There were multiple subcutaneous xanthomatous lesions, primarily over the elbows (Figure 2) and over the knees (Figure 3). Large, partially resected, bilateral Achilles tendon xanthomata were present. Harsh and loud bruits could be heard over most of his major vessels, including the iliac, femoral, and carotid arteries bilaterally. A grade V/VI systolic murmur was heard over the entire precordium with maximum intensity to the right of the sternum in the second intercostal space. There was a left ventricular heave, a suprasternal notch thrill, and P_2 was louder than A_2 with no apparent split.

Laboratory Data

Routine hematology, coagulation studies, and blood electrolytes were all normal, with the exception of a somewhat elevated uric acid level of 6.2 mg%. The fasting blood sugar level was normal at 79 mg%, as was the two-hour post-prandial reading of 84 mg%. The serum cholesterol levels over 11 consecutive days ranged between 832 mg% and 1012 mg%, with an average value of 908 mg%. Lipid evaluation carried out at the Bio-Science Laboratories* gave a cholesterol value of 1050 mg%, serum phospholipids of 684 mg%, serum triglycerides of 147 mg%, and total lipids of 2,351 mg% (see Figure 5 for comparison of preoperative values and post-ileal bypass determinations). On serum lipoprotein electrophoresis an extremely prominent beta band characteristic of type II familial hyperlipidemia was seen.

Posteroanterior and lateral x-ray projections of the chest showed clear lung fields and no apparent cardiac enlargement. The oral cholecystogram revealed normal emptying and no evidence of stones. The aortogram (Figure 4) showed a markedly irregular and narrowed ascending aorta and arch due to atherosclerotic plaque deposits. A systolic pressure difference of approximately 50 mm.Hg. across the aortic valve was present at rest and there was radiographic evidence of aortic regurgitation in association with slight enlargement of the left ventricular cavity. Mild mitral regurgitation was also seen. The coronary arteries were diffusely diseased with the left anterior descending coronary artery primarily involved. (Selective coronary angiography could not be carried out because of the severity of the disease at the coronary ostia.) Left ventricular hypertrophy was evident on the electrocardiogram; this was confirmed by the vectorcardiogram. The carefully monitored double two-step test electrocardiogram was strongly positive with significant ST depressions immediately

*Bio-Science Laboratories, 7600 Tyrone Avenue, Van Nuys, California.

Fig. 4—Aortogram revealing severe atherosclerotic deposits in the root of the aorta and in the aortic valve leaflets, resulting in aortic stenosis and aortic insufficiency.

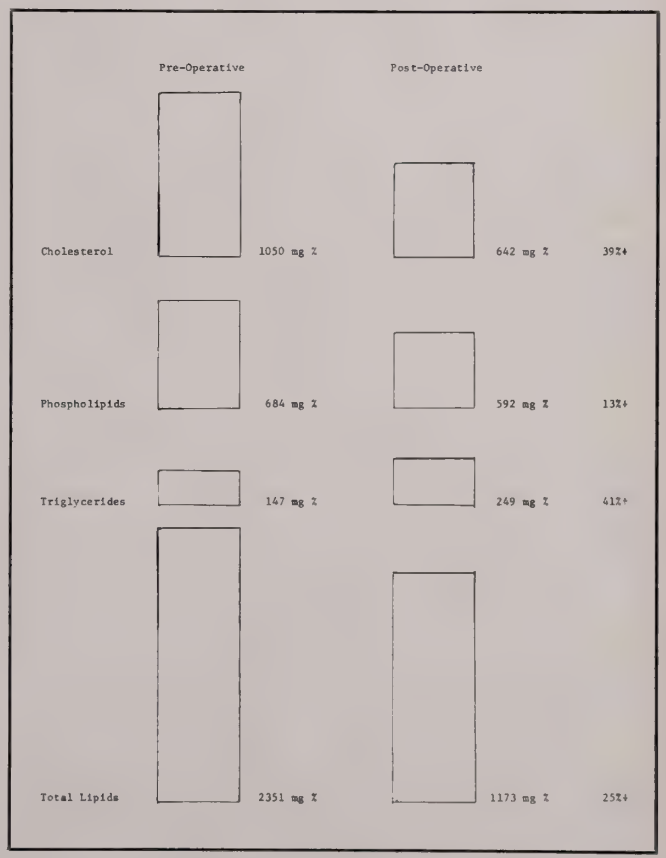

Fig. 5—Serum lipids before partial ileal bypass and six months thereafter.

after exercise.

Surgery

Subsequent to evaluation, the patient was scheduled for a partial ileal bypass operation. During induction he developed supraventricular tachycardia with a rate of 220 beats per minute and a rise in systolic pressure to 250 mm.Hg. The operation was cancelled. On awakening he had severe precordial chest pain radiating down his left arm which failed to respond to nitroglycerin and required morphine for its control. With digitalization, his rate converted to a regular sinus rhythm at 70 beats per minute. At this slow rate his chest pain ceased and his general condition improved. We treated the patient for the next week as if he had sustained a myocardial infarction, but serial enzyme patterns, electrocardiograms, and his clinical course failed to substantiate the diagnosis of acute myocardial necrosis. It was, nevertheless, deemed prudent to postpone an operation.

Two months later he was again taken to the operating room and once again an episode of tachycardia ensued despite adequate digitalization and careful anesthetic induction. This tachycardia cleared as the plane of anesthesia was deepened. Bypass of the distal 200 cm. of the small intestine was carried out from a total small intestinal length of 400 cm. He recovered uneventfully from this procedure.

Subsequent Course

The patient was re-evaluated six months postoperatively. His activity was essentially the same as prior to his operation, he had regained his previous weight, and his bowel pattern had returned to his preoperative one to two bowel movements daily. His blood hematology, coagulation, and electrolyte values were again normal. His serum uric acid had decreased to 5.5 mg%. His fasting blood sugar was 58 mg% and his two-hour post-prandial sugar 79 mg%. Total serum proteins were 6.6 mg% with an A/G ratio of 4.0/2.6. His serum calcium was 9.4 mg%, his serum phosphorus 5.0 mg%, and his serum magnesium 1.7 mg%. The serum carotine and serum vitamin A levels were within the normal range with values of 95 and 30 ngm%, respectively. The electrocardiogram was unchanged.

The serum cholesterol over a consecutive six-day period ranged between 711 mg% and 825 mg%, with an average value of 762 mg%; this is a reduction of 16% from the preoperative average of 908 mg% determined in our chemistry laboratory. Serum lipids, measured at the Bio-Science Laboratories, showed a serum cholesterol value of 642 mg%, serum phospholipids of 592 mg%, serum triglycerides of 249 mg%, and serum total lipids of 1773 mg%. Comparison of these values with the preoperative determinations is graphically shown in Figure 5, revealing a reduction in the serum cholesterol and in the serum total lipids; the serum phospholipids are only slightly reduced and the serum triglycerides are paradoxically elevated. The staining of the beta band on the lipoprotein electrophoretic pattern was diminished.

Though cholestyramine was unsuccessful preoperatively in lowering this patient's cholesterol level, we attempted six months after surgery a four-week trial with a daily dose of 32 grams of cholestyramine, but this regimen failed to reduce his cholesterol level further.

Discussion

Although hypercholesterolemia in the American population is common, familial hypercholesterolemia with well-documented xanthomatous lesions is uncommon, and the occurrence of the homozygous state of this disease is a rarity. If we are to manage a patient with this problem successfully, maximum therapy must be offered as soon as a diagnosis is made and, preferably, before progression to the advanced stage evident in this patient. Early detection is possible with the presence of xanthomatous lesions and an elevated serum cholesterol. Dietary therapy (low cholesterol, low saturated-fat diet), though somewhat effective in the so-called idiopathic hypercholesterolemic patient, is ineffective in the familial form of the disease. Neither do the hypocholesterolemic drugs currently available seem to benefit this type of patient. A moderate measure of success in this patient, as evidenced by the lowering of his serum cholesterol and serum total lipid concentrations, has been achieved by partial ileal bypass. Based on previous experience, we believe that the reduction in the cholesterol level will persist and may become greater. It will take the test of time and the performance of repeat arteriographic studies to ascertain whether the cholesterol reduction proves to be, in some measure, clinically beneficial to this young patient in arresting or retarding the progression of his disease.

Summary

A case report of a 14-year-old patient with severe coronary artery disease, aortic stenosis, aortic insufficiency, arcus senilis, vessel bruits, and diffuse peripheral xanthomatosis, associated with the homozygous form of type II familial hyperlipidemia has been presented. The patient was treated by partial ileal bypass operation, and serum cholesterol and serum total lipid levels were subsequently lowered.

Acknowledgments

We are indebted to Dr. Milton Paul, Director, Division of Cardiology, Willis J. Potts, Children's Heart Center, Chicago, for referring this patient and his family to us.

It's the Law

Drug Manufacturer Not Liable for Intestinal Lesion

The patient developed abdominal pains after taking a drug (HydroDIURIL-Ka-50) for several months. An operation was performed, disclosing a nonspecific lesion in the small intestine. This lesion was removed.

The patient contended that the manufacturer was negligent in not having made more extensive tests before putting HydroDIURIL-Ka-50 on the market. A trial court properly determined that the manufacturer was not negligent in failing to make adequate tests before putting the drug on the market, in view of the long and medically approved use of potassium chloride and diuril separately.

DERIVATIVELY SPEAKING

Atelectasis—from Greek *ateles* (imperfect) plus *ektasis* (expansion)

WHAT'S YOUR DIAGNOSIS?

A 67-year-old white female was admitted to the hospital for evaluation of renal function in relationship to a persistent hypertension. She gave a history of persistent hypertension over several years, and blood pressure at various times was recorded as 200/100. She complained of an occasional "light-headed" feeling. She was also known to have a small hiatus hernia which occasionally caused some dysphagia. On admission her general physical examination was negative except for the noted hypertension and a suggestion of slight left ventricular cardiac enlargement. Pulse was 76 and regular. Electrocardiogram was normal. On her third hospital day she was required to drink four glasses of water for a renal function test. On finishing the fourth glass of water she became nauseated and vomited the water and a small amount of blood. She then began to have severe anterior chest pain radiating across the costal margins. The pain was persistent and became more severe. Examination later that same day revealed the patient to be complaining of severe pain in the left anterior lateral chest. She appeared ashen, but blood pressure was in the normal range. She was perspiring and in obvious distress. Subcutaneous air was palpable in the neck and there was a pleural rub heard over the left lower chest and a pericardial rub heard beneath the lower third of the sternum.

What's your diagnosis? (Turn to page 488).

Ebstein's Syndrome

Although some writers have referred to this condition as a syndrome, it is more commonly known as "Ebstein's malformation." It consists of : (1) a tricuspid valve deformity, resulting in marked dilatation of the right atrium; and (2) an impairment of action of the right ventricle, causing pulmonary arterial blood flow and underfilling of the lungs. Ebstein described this malformation almost 100 years ago. At least 71 cases were reported to 1953 (Kilby *et al.*).

The clinical picture is typical in most cases, but the effect of the aberration on function may vary considerably. Dyspnea and cyanosis may be present at birth or may appear later. The basic deformity follows the same pattern. The posterior leaflet is displaced downward and is adherent to the ventricular wall to a variable extent; the anterior leaflet often forms a long veil-like structure. Considerable variation occurs in the size of the right ventricular chamber and in the thickness of its wall.

Kilby and associates consider the picture complete if: (1) the electrocardiogram is characterized by a pattern simulating right bundle branch block, although the R wave from the right precordium is of low voltage and of a multiphasic type; (2) auscultation reveals a double murmur in the left parasternal region, with perhaps a loud third heart sound; and (3) x-ray shows moderate cardiac enlargement with decreased pulmonary vascular markings.

Angiocardiographic and phonocardiographic findings help to establish the diagnosis. Differential diagnosis should exclude the tetralogy of Fallot, tricuspid atresia, and pulmonary stenosis with interatrial defect. Five of the nine patients who were studied by catheterization at the Mayo Clinic were reported to be alive one to three years later (Kilby *et al.*). Surgical closure of a patent foramen ovale had been effected in one of these patients.

Precancer and Cancer of the Skin*

WILLARD C. PETERSON, JR., M.D.
Minneapolis, Minnesota

PHYSICIANS ARE frequently confronted with differentiation between precancer and cancer of the skin and must make a decision as to biopsy, removal, and follow-up. Many of the lesions to be discussed have characteristics which can aid the physician in his management of these skin growths.

Pseudo-Carcinomatous Hyperplasias

Pseudoepitheliomatous Hyperplasia

In this condition there is a reactive thickening and proliferation of the skin which clinically or histologically may suggest carcinoma. It is found in association with stasis, ulcers, bromoderma, blastomycosis, granuloma inguinale, lupus vulgaris and other chronic processes. Histologically this proliferation may be difficult to differentiate from true carcinoma, and its presence does not rule out the possibility of true carcinomatous change occurring in any of the underlying chronic diseases. The value of its recognition lies in avoiding extensive procedures for a benign reactive condition, with treatment directed at the primary disease.

Keratoacanthoma

This tumor has been recognized with increasing frequency in localized and generalized forms. In the latter type, tumors occur in an eruptive nature in a generalized distribution and heal with scar formation. The disease is considered to have an hereditary basis. The localized variety occurs much more frequently and presents more difficulty. It begins as a papule and may reach 5 to 7 cm. in diameter (more commonly 1 to 2 cm.) in a matter of several months (Figure 1). Involution takes up to 12 months or more. When fully developed the keratoacanthoma is an erythematous to skin-colored nodule with a central crater filled with a keratin plug. Because of its close resemblance to squamous-cell carcino-

*Presented at the Continuation Center, University of Minnesota, October 19, 1967.

ma, surgical excision and histologic examination is the desired treatment .

Premalignant

The word premalignant is confusing, for some of the skin lesions under this heading may never turn malignant while others may already be cancerous. Not all premalignant lesions, such as actinic keratosis, need be removed. Periodic examinations are often sufficient, along with instruction to the patient to report growth or other change in the lesion.

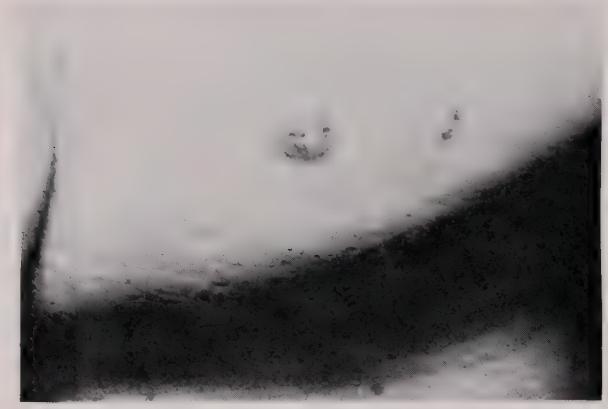

Fig. 1—Keratoacanthoma showing central keratin plug with surrounding elevated border.

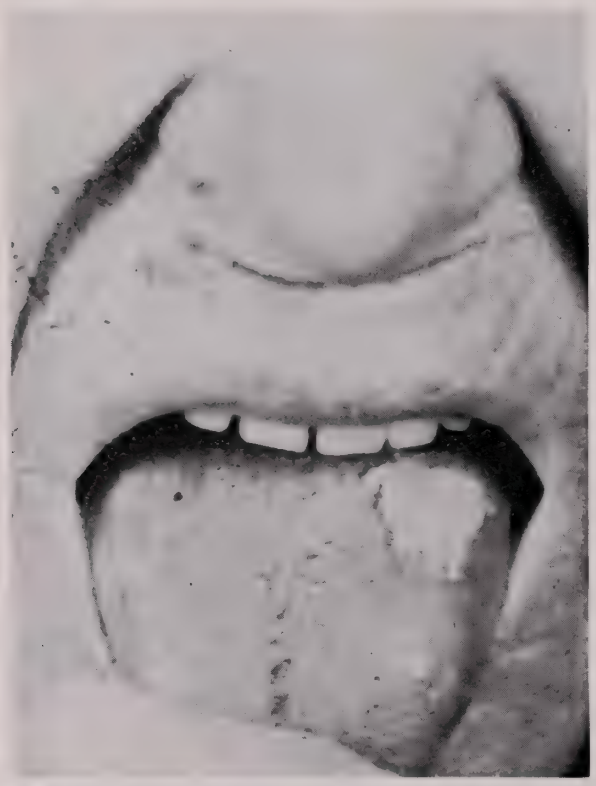

Fig. 2—Leukoplakia on the dorsal tongue with characteristic plaque-like appearance.

In actinic keratosis the patient should avoid any exciting factors, such as prolonged sun exposure.

Actinic Keratosis (Senile Keratosis and Cutaneous Horn)

These common lesions usually occur on exposed areas and in the latter decades of life. They may be single or multiple and occur more often in individuals who have undergone considerable sun exposure. Hereditary factors may also be involved, such as fair complexion. The lesions have a verrucous or scaly appearance, may be erythematous or pigmented, and occasionally can be detected only by palpation. Actinic keratoses generally occur on skin which shows other evidence of actinic changes. Squamous-cell carcinoma will appear in about 25% of these cases.

Treatment is usually surgical. Some individuals may have so many of these lesions that any of the surgical methods such as curettement, electrocautery or excision are impractical. In these cases, regular examinations with removal of those lesions showing growth or other changes may have to be the form of management.

Leukoplakia

This condition occurs on the mucous membranes, most notably the mouth, penis, and vulva. In the oral cavity, the lips, gums, cheeks and dorsal tongue are most frequently involved. On the penis, the glans and foreskin in uncircumcised older men are susceptible. The condition varies in both symptoms and appearance with the duration of involvement. At first there are no symptoms; later, burning and discomfort occur with minor irritation. The appearance is that of superficial patches of various shapes which may be glistening and in some areas even mildly pigmented. Later the lesions thicken and may become verrucous with fissures and ulceration. This condition may exist for years without malignant change; yet induration may begin insidiously around an inflamed area, ulcer, or fissure, with resulting carcinoma of an invasive nature (Figure 2). Treatment of the leukoplakia itself consists of removing any chronic irritations (e.g., carious teeth, poorly fitted dentures, smoking). In some cases following removal of an irritant the leukoplakia may

regress. Isolated areas may be treated with liquid nitrogen, electrocautery and, in extensive cases, plastic surgery. When carcinoma occurs, surgical excision is indicated.

Arsenical Keratoses.

Arsenic in the inorganic form may induce keratoses as well as basal and squamous-cell epitheliomas. The keratoses that occur following the ingestion of inorganic salts of arsenic are found with greatest frequency on the palms and soles. Elsewhere, Bowen's disease and basal-cell epitheliomas may occur. The interval between ingestion of arsenic and the development of the keratosis may vary from months to years. On the palms and soles the lesions are discrete keratotic growths somewhat resembling warts. At times they may become inflamed due to irritation. Malignant change occurs in approximately 20% of the cases. Treatment of this condition is unsatisfactory, because there are usually too many keratoses for surgical removal to be practical. Therefore, observation is used with frequent examinations for signs of malignant change. When this occurs excision is the preferred treatment.

Radiodermatitis.

This condition may be either acute or chronic. From the standpoint of potential malignancy, the chronic form is of most concern. Chronic radiation changes may occur following a known acute phase or may slowly make their appearance without this first stage. Clinically the skin in chronic radiodermatitis is dry, smooth, and atrophic. Telangiectasis and loss of hair may occur. In addition, there may be freckle-like spots or diffuse pigmentation as well as diffuse or spotty loss of pigment. If on the hands, the nails may become lusterless, brittle and discolored. Dystrophic changes of the nails may occur, such as ridging, splitting and delayed growth. With time keratoses may occur in these areas. These lesions are hard little plugs, brown to black in color, which may ulcerate with subsequent malignant change. When this occurs, the usual form of tumor is squamous-cell carcinoma. However, basal-cell epithelioma, sarcoma, and malignant melanoma have been recorded. In the treatment of mild chronic radiodermatitis various ointments may be used; however, with progressive or severe change, surgical methods such as grafting and excision of ulcers is of prime importance. Once malignant change has occurred, surgical excision, if feasible, is the indicated treatment.

Superficial Epithelioma

Lesions in this category are already carcinomas with the attendant potentials of this type of neoplasia and are therefore removed whenever diagnosed.

Bowen's Disease

This tumor is a specialized superficial epithelioma which clinically appears as an erythematous scaling plaque which may resemble psoriasis (Figure 3). Although there is usually no infiltration, ulceration may occur. Bowen's disease may be present on the exposed skin or on covered areas as well as on certain mucous membranes. When it is situated on the glans penis, vulva, or oral mucosa, the term erythroplasia (of Queyrat) is used. There appears to be an increased incidence of visceral cancer in individuals who have Bowen's disease, especially on the normally nonexposed areas.[1] This tumor may grow slowly, remain in situ for many years, and then transform to an invasive growth with metastasis. Treatment consists of curettement, electrocautery, or surgical excision, for these tumors are somewhat radioresistant.

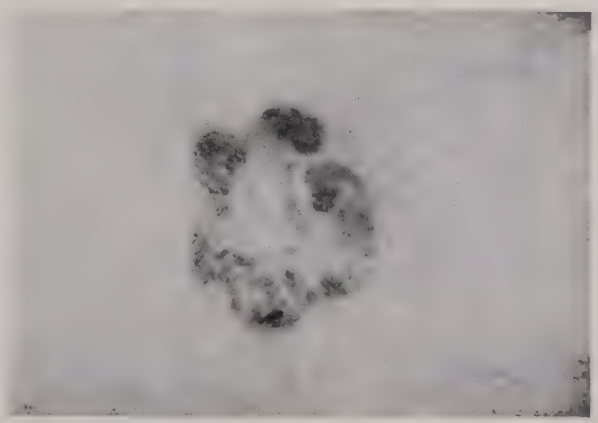

Fig. 3—Bowen's disease: note eczematous nature along with areas of early superficial ulceration.

Malignant

Neoplasia involving the skin shows a wide range of malignant potential. Basal-cell epitheliomas do not as a rule metastasize. In fact there appears to be increasing evidence that cu-

taneous squamous-cell carcinomas have a low rate of metastatic potential. On the other hand, melanomas may metastasize early and extensively before they are seen by the physician. Treatment of these lesions should be based upon the nature of the tumor and its clinical characteristics regarding growth and spread.

Basal-Cell Epithelioma.

Approximately 80 to 90 percent of all epitheliomas of the skin occur on the head and neck.[2] Basal-cell epithelioma occurs most frequently about the nose, eyelids and upper face. In most instances these tumors are single. However, some individuals have a greater tendency to develop these lesions and may have multiple tumors. Multiple basal-cell tumors may be seen after arsenic ingestion (Fowler's solution) as well as in the so-called basal-cell nevus syndrome.

The lesion may first be clinically evident as a small (1-2 mm.) erythematous macule or papule, gradually enlarging into a waxy nodule, which frequently shows fine telangiectatic vessels on its surface. With time, scaling, bleeding, crusting, and ulceration may occur (Figure 4). Even with ulceration and crusting the border of the lesion frequently maintains its waxy characteristic. In approximately 10 to 20 percent of these tumors, pigmentation may be present. Metastases are extremely rare with this tumor; however, when they do occur, the mortality rate is high. Treatment consists of biopsy of suspicious lesions; and if basal-cell epithelioma is shown to be present, excision, electrosurgery, radiation, or curettement may be used. The choice of modalities depends upon the size and location of the tumor as well as on the experience of the physician.

Squamous-Cell Carcinoma.

This tumor, like the basal-cell epithelioma, is more common on the head and neck in middle age and beyond. However, like the latter tumor it may be found anywhere on the body, especially the hands. The basal-cell epithelioma is more often found on the face about the nose, upper lip, eyelids, forehead, temple; whereas the squamous-cell carcinoma is more frequent on the lower lip and mucocutaneous junctions. However, it should be emphasized that this tumor may occur at any location where a basal-cell epithelioma can be found. The squamous-cell carcinoma usually begins as a scaling lesion and subsequently becomes infiltrated with a margin which may be rolled and hyperemic. The tumor may grow outward, inward, or both —with destructive ulceration occurring; there may also be extension into connective tissue, cartilage, periosteum and bone. In some instances metastatic extension occurs to the regional lymph nodes—more frequently with lesions on the hands (Figure 5). Early treatment of this tumor with surgical excision, curettement, radiation, or electrosurgery gives good results in experienced hands. Naturally, when deep infiltration has occurred or metastases are present, results are less favorable.

Malignant Melanoma

Of all skin tumors, nevi are the most prevalent. Young adults average about 40 benign nevi.[3] These lesions vary in size, color, and

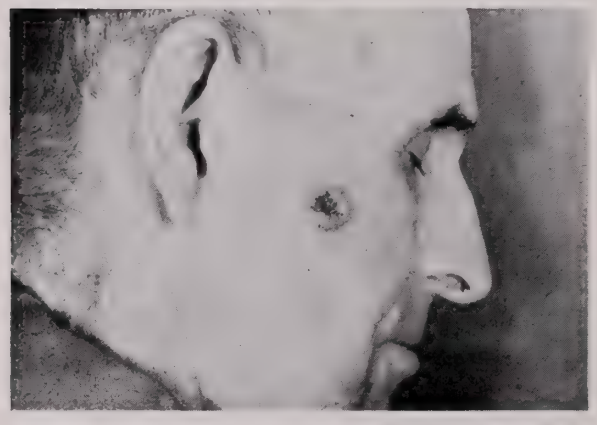

Fig. 4—Basal-cell epithelioma showing central area of crusting with surrounding wax-like border.

Fig. 5—Squamous-cell epithelioma on the dorsal hand with ulceration of its surface.

amount of pigment. Some are flat, others elevated. Nevi on the palms and soles are usually flat, pigmented lesions, histologically of a junctional nature. Malignant change may occur at any age; however, the sixth decade or beyond is the period of highest incidence. About 25 percent of melanomas arise from pre-existing benign nevi; in the remaining cases either the tumor has arisen de novo or the primary nevus cannot be found. Most of these pre-existing nevi are of the junctional type. This does not mean, however, that all junctional nevi are destined to undergo malignant change.

Melanomas which arise from a pre-existing nevus are to be differentiated from those referred to as lentigo maligna. This latter type occurs as a rule in older people and is a superficial, slow-growing tumor with a low grade of malignancy.

Melanomas vary in their clinical appearance. Some are flat, others elevated; they may be darkly pigmented or can in fact have little or no pigment present. With time the lesion usually ulcerates and becomes crusted. Metastases occur early with both local and systemic involvement, especially to the liver and lungs.

The physician is frequently confronted with the problem of removing benign nevi. It is generally accepted that nevi of the nail beds, growing nevi after childhood, those that are subjected to chronic irritation, and unusual or atypical nevi should be prophylactically removed. When a diagnosis of melanoma is made, the treatment is wide surgical removal, node dissection, and at times perfusion. Whether all these procedures will be employed is determined in each individual case.

Paget's Disease

Paget's disease as applied to cutaneous malignancy refers to a rare tumor which most frequently involves the areola and nipple in females; however, it may occur on or near the male or female genitals, the perineum and axilla. This lesion is usually erythematous, with scaling, oozing and crusting; and infiltration may be present. Clinically it can resemble Bowen's disease, psoriasis or simple eczema. When involvement of the breast occurs, retraction of the nipple may be present. Its origin is generally considered to be an intraductal or adenocarcinoma of one or more mammary ducts. The mammary glands being apocrine in nature have analogues in the other areas mentioned, which probably explains the extramammary occurrence. Treatment is surgical, the extent of the procedure depending on the site of the tumor.

Sarcomas

Sarcomas originating in the skin are rare. They are usually slow-growing and do not readily metastasize. With respect to the multiple idiopathic hemorrhagic sarcoma, this tumor probably has multiple foci of origin rather than metastatic spread from an original locus.

Dermatofibrosarcoma Protuberans

This tumor is a rare slow-growing connective-tissue tumor originating in the dermis. Clinically it may show either an indurated papule or plaque as well as multiple nodules. It is slow-growing and metastases occur infrequently, though it may be invasive. Histologically this lesion is composed of strands and whorls of collagen with only slight atypicality. Treatment is by surgical excision. This tumor is to be contrasted with the more malignant subcutaneous fibrosarcoma which usually arises in the deep subcutaneous layers of fascial tissue, grows rapidly and readily metastasizes.

Multiple Idiopathic Hemorrhagic Sarcoma (Kaposi's)

In this condition the patient shows an eruption of bluish-red papules, plaques and nodules (Figure 6). The most common location is distally on the lower extremities. It is more common in men. Visceral as well as lymph-

Fig. 6—Kaposi's sarcoma: note plaques, papules, and nodules.

node involvement is known to occur. Any organ may be involved, most commonly the gastrointestinal tract, liver, lungs, intra-abdominal lymph nodes and heart. The disease may be variable in its clinical behavior; some lesions may grow and ulcerate, while some may regress. As a rule the general course of the disease is protracted, with some cases having a course of 10 to 20 years or more. Death, when it occurs, may be due to internal hemorrhage, to intercurrent infection with debilitation, or to lymphoma of one type or another. Treatment is not satisfactory, though conservative use of fractional x-ray (filtered) may be employed as well as chemotherapy and cobalt infusions. Beyond this, supportive measures should be used.

Lymphomas and Myelosis*

Any of the myeloses may first manifest themselves clinically in the skin or involve the skin later in their course. As a rule the eruptions are nonspecific and resistant to therapy. In many instances it is this very resistance which leads to a skin biopsy and disclosure of the underlying disease. Within the lymphoma group, mycosis fungoides is of particular interest, for it may remain localized in the skin for many years and has a somewhat characteristic clinical course.

Mycosis Fungoides

This term is used to describe a rare disease which appears to fall within the broad category of lymphoma, manifesting itself first in the skin and following a fairly characteristic course. Mycosis fungoides may begin as a banal dermatitis, only to progress to a fatal, often protracted, termination. The disease is divided into three stages, although all three need not occur in the course of the condition. Also, the various stages may overlap, with some cases showing characteristics of all three stages at one time. At its onset, mycosis fungoides may appear as a nondescript eczematous eruption, though often it may be psoriasiform in nature. This initial stage may continue for a period of years, with the patient maintaining relatively good general health. Eventually the eruption becomes characterized by polymorphism, bizarre patterns and vivid coloration. Infiltration occurs gradually, leading to the so-called plaque stage. Ulceration may occur at this point. Still later the third stage occurs and is characterized by nodules and tumors, which may appear on pre-existing plaques or arise on previously non-involved skin. The tumors have a tendency to become deep necrotic ulcers. The prognosis in this condition is serious, though remissions do occur, and the course may be prolonged. Treatment in the past has consisted of roentgen therapy along with supportive measures. Recently several chemotherapeutic agents have been used, though as yet it is difficult to judge their relative efficacy.

Other

Several other forms of tumors found on the skin should be mentioned. These include the so-called benign or nevoid adnexal tumors such as sebaceous, apocrine, and eccrine neoplasms, which may remain benign or become malignant. Some of these tumors, such as syringomas, may be suspected clinically; however, many have no characteristics by which to diagnose them other than histologic examination following surgical removal.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(From page 482)

A left thoracotomy was performed one hour later and this revealed a ruptured esophagus with a two-centimeter laceration of the medial wall of the esophagus just above the diaphragm. The rent was repaired and the patient made an uneventful recovery.

Incarceration of Transvenous Pacemaker Electrode

Removal by Traction

AYDIN M. BILGUTAY, M.D.
N. KENNETH JENSEN, M.D.*
JOSEPH J. GARAMELLA, M.D.*
W. ROBERT SCHMIDT, M.D.*
MICHAEL F. LYNCH, M.D.
Minneapolis, Minnesota

CARDIAC PACING by a transvenous electrode has extended this therapeutic modality to patients too ill for thoracotomy and epicardial electrode pacing. Thus the transvenous electrode is often used temporarily in rhythm disturbances due to myocardial infarction. The present development of demand impulse generators, which avoid the risk of competition stimulation with resultant ventricular arrhythmia and fibrillation, will greatly increase the usefulness of the transvenous electrode in the management of myocardial infarction.

Transvenous pacing has been beset with many complications. The following complications related to transvenous electrodes have been reported in the literature.[1-7] While improvement of the impulse generators may reduce their related complications materially, the problems of the transvenous electrodes remain.

Arrhythmias during insertion
Bleeding
Infection
Thrombophlebitis
Wound sepsis
Subacute bacterial endocarditis
Air embolization
Phrenic stimulation
Fracture of electrode
Erosion of the electrode through the skin
Perforation of the right ventricle
Displacement of the electrode with loss of pacing

The transvenous electrode is quickly incorporated into the right ventricle wall, first by mural thrombus formation which is soon converted to scar by fibroblastic ingrowth. The somewhat bulky one inch of flexible electrode leading to the distal platinum tip, designed to minimize the risk of ventricular perforation, allows the electrode to be held firmly in this fibrous tissue. This is desirable

*Clinical Associate Professor of Surgery, University of Minnesota.

as displacement of the electrode with loss of pacing is prevented. However, when the need for electrode removal arises, difficulties result from the fixation.

The following case reports illustrate the problem of removal of the electrode.

Case Reports

Case 1

A 43-year-old male was admitted to St. Mary's Hospital, Minneapolis, on January 24, 1967, following the onset of substernal crushing pain. Initial electrocardiogram showed posterior myocardial infarction. On the fourth day, first degree and intermittent second degree heart block appeared, progressing to intermittent complete heart block with ventricular rate of 50 to 60 per minute. On the tenth hospital day, ventricular rate dropped to 30, and intravenous Isuprel was required to maintain adequate cardiac output. A transvenous pacemaker was implanted and 20 days later the patient was discharged from the hospital with the pacemaker functioning. After two weeks, the impulse generator was turned off by percutaneous needling of the unit as sinus rhythm had returned. He remained well.

Eighteen weeks after insertion, removal of the pacemaker was undertaken with local anesthesia. The impulse generator was removed from the anterior chest wall and the electrode exposed where it entered the jugular vein. The electrode could not be pulled from the heart. With heavy pull on the electrode, the electrocardiogram would show either bradycardia or ventricular tachycardia. It was elected to abandon removal of the full electrode and, accordingly, it was cut and the impulse generator removed from its pocket. Ten days later, infection developed about the remaining electrode with thrombosis of the left subclavian and jugular veins.

Coagulase-positive Staphylococcus aureus bacteremia developed. This was controlled with antibiotics, but the wound on the chest wall remained purulent. It was evident that the electrode should be removed. Hand traction was again unsuccessful. Repeatedly, the electrode could be pulled out of the vein and stretched for a distance of three or four inches, but ventricular tachycardia would ensue. Upon release of the electrode, it would retract into the jugular vein for the entire distance it had been withdrawn. Sustained traction well below the pull that produced ventricular arrhythmia was then arranged by attaching the end of the electrode to a cord leading to a half-pound weight suspended over a pulley at the end of the bed (Figure). Removal was accomplished in the course of a few minutes.

Case 2

A 31-year-old woman was admitted to North Memorial Hospital, Minneapolis, on July 17, 1967, with a history of sudden onset of episodes of syncope. The electrocardiogram showed complete heart block. A transvenous pacemaker electrode was introduced

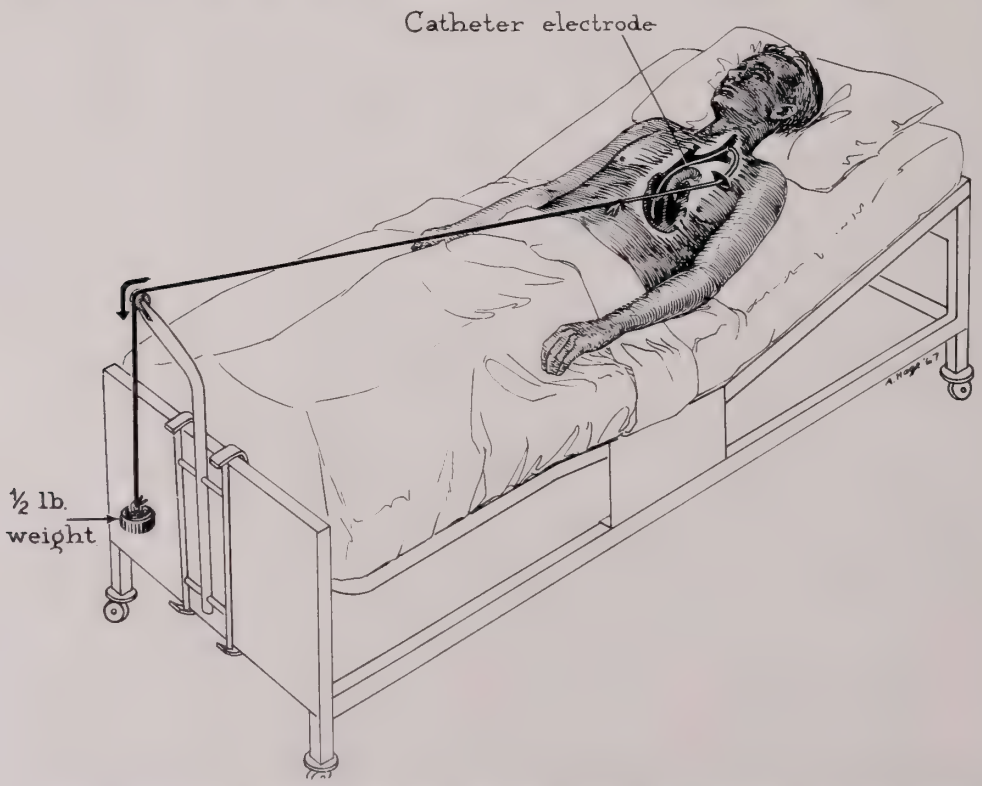

Figure: Diagram showing sustained traction applied for removal of incarcerated transvenous pacemaker electrode.

through the right saphenous vein and connected to an external pacemaker. Extensive studies failed to show the etiology of heart block. As her own rate never showed signs of returning to sinus rhythm, and because there was evidence of phlebitis developing in the right leg, on July 27, 1967, an epicardial fixed rate pacemaker was implanted through a thoracotomy. Attempted removal of the transvenous electrode after surgery met with resistance and it appeared that the electrode was incarcerated in the ventricle and/or along its course in the inferior vena cava and saphenous vein. Sustained traction was then applied to the end of the electrode over a pulley, utilizing a one-pound weight. The weight was gradually increased to a two-pound weight and in the course of a few minutes the removal of the catheter was accomplished.

Discussion

Review of the literature indicates that under similar circumstances others have pulled the electrode out of the vein as far as it would come without ventricular difficulties, then cut it off and let the remainder of the electrode retract into the vein. They have then resorted to cardiotomy* to remove the remainder of the electrode.[1,6,7] Gentle steady traction can also be utilized for removal of direct myocardial wires, inserted at time of surgery for other cardiac lesions, where temporary pacing is planned. It has been our experience that not infrequently such myocardial wires could not be completely removed, and we have had to be content with pulling the electrode out as far as it would come and cutting it off at this point, hoping the uncovered portion would not be troublesome.

*See Test Your Word Score Page 511.

Summary

A transvenous electrode may become densely adherent to the endocardium of the right ventricle and resist removal.

Adherent electrodes have been removed by gentle, steady traction in two such instances. This method may be worthy of trial before cardiotomy is undertaken to remove an incarcerated electrode.

Reprisal

What sin did Miriam commit that she should be smitten with leprosy?

She had incensed the Lord by presuming to criticise Moses for having married an Ethiopian woman and for being one of God's favorites.

And the Lord came down in the pillar of the cloud, and stood in the door of the tabernacle, and called Aaron and Miriam: and they both came forth.

And the cloud departed from off the tabernacle; and, behold, Miriam became leprous, white as snow: and Aaron looked upon Miriam, and, behold, she was leprous. (Numbers 12:5, 10.)

YOUR HEALTH—MR. PRESIDENT!

William Henry Harrison (1773-1841)

The health record of our ninth President and nation builder, William Henry Harrison, contains only one sensational entry: narrow escape from death by a bullet. During Harrison's governorship of Indiana Territory a disgruntled Indian shot at him through a window while he sat in his home with Baby John in his arms. Fortunately neither the father, destined to become President, nor the infant son, destined to sire a President, was struck.

As child and man William Henry Harrison was of average health, neither robust nor frail, and enjoyed outdoor sports such as swimming, fishing, and especially horsemanship.

At the conclusion of a classical college course at Hampden Sydney, fertile soil for aspiring medical students, young Harrison began the study of medicine under Dr. Rush at the College of Physicians and Surgeons in Philadelphia. After only a few months, however, family funds ran too low for him to continue and he left Anatomical Hall to enter the army as an ensign destined to become the famous general and military strategist of We-have-met-the-enemy fame, with the sobriquet of Old Tippecanoe.

While actively engaged in the Indian Wars and the War of 1812 Harrison was laid low with army camp fever, Nature's insidious reprisal for logistic failure to provide adequate food, clothing, and shelter for the soldiers in the field. Before his recovery was complete he suffered a relapse due to overexertion while directing restoration on flood-damaged neighboring property.

Harrison was a naturally temperate man; but if his sobriety needed reinforcement, military life provided it. Of the mortality in the army due to alcoholism he said: "At least four fifths of my brother officers died from the effects of intoxication."

On Harrison's bone-chilling inauguration day, while he delivered his one-hour-and-forty-five-minute acceptance speech without hat or coat, he caught a severe cold. While convalescing he summoned his personal physician—not to prescribe for him but to discuss his several chronic ailments: neuralgia of the head and limbs; constipation, for which he swallowed an abundance of cathartics; and dyspepsia, for which he had himself ineffectually prescribed first a meat diet and then a starvation regimen. Nevertheless, the doctor did prescribe: relaxation and serenity plus cupping.

When only partially recovered from his cold Harrison rashly ventured forth one inclement day to do some marketing, the aftermath of which indiscretion was pneumonia, for the fever of which he deluged his system with water "to keep up his strength." His subsequent failure to improve brought in a team of five doctors who found that in addition to pneumonia their patient showed symptoms of intestinal inflammation and jaundice; whereupon they instituted a procedure of "topical depletion, blistering and appropriate internal remedies which subdued his lungs and liver," but not his stomach and intestines.

Treatment was of no avail. Old Tippecanoe died on April 4, 1841, after completing one month of his presidential term, the first United States President to die in office. The death report certified that "bilious pleurisy" was responsible for his demise. No autopsy was held. Had one been conducted, however, it would have failed to reveal any concrete evidence of the psychic ravages that constitute the price of high office and that historians agree must have contributed appreciably to Harrison's final dissolution.*

Endotoxic Shock in Obstetrics and Gynecology*

JOSE C. PACHECO, M.D.**
WILLIAM J. MARTIN, M.D.†
Rochester, Minnesota

Shock is a condition of protean causes and manifestations. Among the latter, there is arterial hypotension and consequent inadequate perfusion of oxygenated blood to the body tissues. Such perfusion depends on three components: the circulating volume or blood, the vascular channels, and the pump or heart activating this ternary system. According to the component affected, several varieties of shock may ensue. Hypovolemic shock reflects loss of circulating volume either to the exterior or into internal body compartments. Cardiogenic shock indicates an impaired cardiopulmonary pump. Decreased peripheral resistance resulting from peripheral vasodilatation, while not invariable, may characterize the type of shock caused by bacterial toxins.

Bacteremic shock may complicate bacterial invasion of the bloodstream. A sustained, often precipitous decrease in systolic blood pressure to 80 mm of mercury or below is noted in a person previously normotensive, and bacteria are recovered from blood cultures obtained during or shortly preceding the hypotension.[1-4] Because blood pressure may not faithfully reflect the status of the microcirculation to various body organs, inadequate tissue perfusion may be present prior to the clinical detection of hypotension. Notwithstanding, sustained systemic arterial hypotension remains the essential clinical manifestation of bacteremic shock since more sensitive clinical methods of detection currently are unavailable.

A simple but not exact division of bacterial toxins is that of (1) exotoxins, as produced by strains of gram-positive cocci, and (2) endotoxins, as released by gram-negative bacilli or obtained after their autolysis. The more frequent toxin concerned in the genesis of bacteremic shock is the endotoxin of gram-negative bacilli. Endotoxin is a polymolecular phospholipid-polysaccharide-protein complex in which the polysaccharide provides antigenic specificity and the lipid fraction purveys toxicity. Endotoxic shock is that variant

*Presented as a Seminar in Obstetrics and Gynecology under the sponsorship of the Mayo Graduate School of Medicine.

**Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Obstetrics and Gynecology.
†Mayo Clinic and Mayo Foundation: Section of Medicine.

of bacteremic shock resulting from the activity of endotoxin subsequent to gram-negative bacillary invasion of the bloodstream. This complication occurs in 20 to 30% of patients having bacteremia due to gram-negative bacilli.

Portal of Entry

At the Mayo Clinic in a series of 303 patients with bacteremia due to gram-negative bacilli, there was a urinary portal of entry in about 50%.[5] The biliary tract was the portal in 10%, and the rest of the gastrointestinal tract in 15%. The female genital system was indicted in 5%. In another 5%, other sources such as skin, postoperative wounds, and the respiratory tract were responsible. In 15% a portal was not evident. In about 50%, bacteremia occurred after surgical or manipulative procedures; two thirds of the procedures were genitourinary and one third, gastrointestinal.

Endotoxic shock is the most frequently encountered variant of bacteremic shock in pregnant and gynecologic patients. In about 50%, it is associated with induced abortion.[6,7] In these patients, other predisposing conditions and therapies include pyelonephritis, manipulation of the urinary tract, ruptured membranes, pelvic abcess, chorioamnionitis, advanced neoplasms, and operative obstetric and gynecologic procedures.

Causative Microorganisms

Strains of *Escherichia coli* cause about one half of these infections; *E. coli* and *Klebsiella-Enterobacter* organisms, together, are causative in two thirds. In recent years, *Pseudomonas* has displaced *Proteus* as the next most common pathogen in some series. Less common pathogens include *Bacteroides*,[8] *Paracolobactrum*, and *Achromobacter*.

Physiologic and Pathologic Considerations

The pathogenesis of human endotoxic shock remains incompletely understood. As data accumulate, it becomes apparent that the complication is not the result of a single hemodynamic aberration; some patients have reduced cardiac output and normal or increased peripheral arterial resistance, whereas others have essentially normal cardiac output or one that is increased two to three times normal and reduced peripheral arterial resistance.[9] As a generalization, in the normovolemic patients early in shock, there is a high cardiac output and low peripheral resistance. Later in the process, reduced cardiac output may ensue. In contradistinction to these patients, those who are hypovolemic when endotoxic shock develops may have a low cardiac output and high peripheral resistance.

Endotoxin apparently acts indirectly on blood vessels through the medium of an unknown component in blood and induces tetany-like activity of the vascular beds near the arteriolar level.[10] Vasoconstriction predominates initially, but alternating vasodilatation of progressive duration eventuates in vascular atony. Consequently, when vascular capacity is thus increased, blood is sequestered therein and diminished amounts are returned to the heart. Incomplete cardiac filling may result in reduced cardiac output, more profound hypotension, and diminished arterial blood flow. As a result, there is inadequate perfusion of vital tissues and organs with oxygenated blood. The anoxia prevents normal cellular metabolism and anaerobic cellular reactions dominate, with formation of acid metabolites such as lactic acid and pyruvic acid to the point of metabolic acidosis. The anoxic cells may release excessive amounts of potassium, resulting in hyperkalemia. Increasing amino-acidemia may manifest the anoxic liver's inability to metabolize the increased load resulting from tissue breakdown.

In endotoxic shock, blood volume usually is adequate, but perfusion is ineffective because of peripheral pooling; and neither in experiments nor in humans is there evidence of adrenal failure, even when the subject is moribund.[11,12]

In human subjects to whom repeated intravenous injections of the endotoxin of *E. coli* have been given, clinical responses are progressively lessened. As tolerance increases among such volunteers, serum antibody titers and complement titers rise.[13]

Autopsy studies frequently do not reveal findings that might be considered specific or diagnostic of endotoxic shock. Lesions of the kidneys associated with renal insufficiency may include renal tubular necrosis due to shock, but in some cases, nephrotoxins such as certain

antibiotics might also be responsible. In a few cases there is a distinct lack of correlation between severe renal failure and morphologic alterations of the kidneys. To date Mayo Clinic investigators have not found evidence suggestive of the generalized Shwartzman phenomenon or unequivocal evidence of disseminated intravascular coagulation.[14]

Clinical Features

Usually there is prodromic* fever, followed by moderate hypotension and tachycardia; initially the patient is restless but alert and maintains a relatively good urinary output. If the etiologic factor is septic abortion, the patient has uterine and adnexal tenderness and purulent vaginal discharge. Recognition of the complication and its pertinent treatment at this stage usually lead to recovery. Later, due to extension of the infectious process and to failure of homeostatic mechanisms, hypotension may become severe and the patient may appear lethargic, cold, and pale. Weakening of the pulse, tachypnea, collapse of superficial veins, and oliguria may also be observed. Metabolic acidosis (perhaps largely due to lactic-acidemia),[15] semicoma, refractory hypotension, cyanosis, dilated and sluggish pupils, gallop rhythm, hypothermia, and anuria signal the terminal stage of the complication.

The prognosis largely depends on early recognition of the syndrome as well as early institution of pertinent treatment. In different series, mortality rates vary from about 30% to 80%; at the Mayo Clinic it has been 37%.[3] The prognosis is also related to the nature and severity of the initial lesion, the presence of underlying disease, previous therapy, and such complications as superinfection and metastatic infection.

Treatment

Management of bacteremic shock presumes close scrutiny of potential candidates, because prompt detection and treatment are essential to minimizing the mortality rate. Increases of temperature and pulse rate associated with decreases of blood pressure and urinary output in such patients dictate the need for obtainment of samples of blood for culture and consideration of the need for empiric antibacterial therapy if no other explanation is immediately forthcoming. If a pertinent, although empiric, antibacterial regimen is not employed, or not employed early in the infection, the essential problem is not being attacked and the likelihood of recovery is correspondingly reduced. Other supportive procedures are designed only to maintain the patient's life until antibacterial therapy can control the overwhelming infection that is the essential cause of the vascular collapse. Occurrence of the complication in the pregnant woman obviously entails additional considerations of therapy and its effect on the fetus.[16]

Antibacterial Therapy

In-vitro inhibition tests, and frequently results of blood cultures as well, are mainly of retrospective value in the management of bacteremia due to gram-negative bacilli, because antibacterial therapy is often begun empirically before such data are available. To postpone antibacterial therapy until the results of these tests are reported would mean a delay of 24 to 72 hours and an increased chance of mortality.

Empiric antibacterial therapy is initiated either on report of positive blood cultures or in cases where bacteremia is likely, when blood has been drawn for culture. In the past, a tetracycline combined with streptomycin, or alternatively, chloramphenicol and kanamycin, has been the regimen given most often under these circumstances at the Mayo Clinic. More recently we have been investigating the combined use of cephalothin and a polymyxin (polymyxin B and colistin) given under these circumstances. Other possible empiric regimens that may warrant investigation are cephalothin plus kanamycin and ampicillin given with kanamycin or a polymyxin.

There are disadvantages of empiric use of such combined antibiotic therapy. These include the dual depressive effect on the gram-negative elements of the flora, making superinfection more likely. However, periodic study of the sputum and stools during therapy may reveal any floral changes and impending superinfection. Streptomycin, kanamycin, the polymyxins, and perhaps cephalothin are possibly nephrotoxic; excepting cephalothin, these drugs may cause a curariform effect that may be manifested by cardiac arrest and respiratory depression. Streptomycin and kanamycin are oto-

*See Test Your Word Score Page 511.

toxic, but the latter is more likely to cause deafness. Chloramphenicol is hematotoxic. The polymyxins also may cause cerebellar ataxia and other neurologic complications. It appears unwise to employ drugs in combination, which share a significant toxic effect, since such use may enhance the likelihood of occurrence of such toxicity.

With the advent of newer drugs, there has been a reevaluation of the policy of the empiric use of combined antibiotic therapy. Use of a polymyxin has a disadvantage because *Proteus* and *Bacteroides organisms* are usually resistant to it. Kanamycin is inadequate as a single agent because a number of *Pseudomonas* and most *Bacteroides* organisms are insensitive to it. Ampicillin is inactive against most *Klebsiella-Enterobacter* organisms, most *Proteus* bacilli that are indole-positive, and *Pseudomonas* organisms. Cephalothin is not active against all *Klebsiella-Enterobacter* organisms, *Bacteroides*, and indole-positive *Proteus* bacilli and usually is inactive against *Pseudomonas*. To date, there is no single agent available that assures complete coverage against gram-negative bacillary infections.

Currently, when the patient's course is unsatisfactory and microbiologic data are reported, the empiric regimen may be replaced with a more pertinent drug, in keeping with results of tests of in-vitro bacterial susceptibility. Against *E. coli*, such drugs as ampicillin, cephalothin, or a polymyxin may be applicable. As a generalization, strains of *E. coli* are susceptible to streptomycin, the tetracyclines, and cephalothin in about 50% of cases; these bacilli are susceptible to ampicillin, kanamycin, the polymyxins, and chloramphenicol in 80% or more of cases. The same generalizations are applicable to *Klebsiella-Enterobacter* organisms except that only about 20% to 30% are susceptible to streptomycin and to the tetracyclines, 50% to 70% are susceptible to the polymyxins, and about 10% of these bacilli are susceptible to ampicillin.

Among other drugs, penicillin G, ampicillin, cephalothin, and novobiocin are active against the indole-negative *Proteus mirabilis*, which causes 80% to 90% of clinical infections due to *Proteus* organisms. Cephalothin is active in only about 10% to 20% of infections caused by indole-positive *Proteus* organisms, that is, *P. vulgaris*, *P. morganii*, and *P. rettgeri;* chloramphenicol also may be effective, but differences between in-vitro and in-vivo results are frequent with this drug against these organisms. Consequently, kanamycin may be the drug of choice against indole-positive organisms. Polymyxin B or colistin is used especially against *Pseudomonas* organisms. Despite the availability of the newer drugs, a tetracycline often is preferred in bacteremia due to *Bacteroides* organisms; chloramphenicol is also effective against these organisms; penicillin G and cephalothin may be active against certain strains of *Bacteroides*.

Supportive Therapy

Considerable controversy exists regarding ancillary management of these infections, but those measures that are frequently employed are mentioned at least for the sake of completeness.

Important among these measures is the management of fluid and electrolyte deficits. If hypovolemia is present, it should be corrected; however, overadministration of fluids, especially of saline, during oliguria can embarrass cardiac function and induce pulmonary edema. Replacement of blood may be required in such patients as those having uterine bleeding or underlying hematologic disease. Monitoring of central venous pressure indicates the competence of the heart to accept and expel a given volume of blood and may serve as a guide to volume repletion. Fluids can be cautiously given as long as the central venous pressure is low or normal, that is, 5 to 15 cm of water.

Antiacidotic measures are being investigated, and although acidosis can be corrected by infusion of sodium bicarbonate, levels of lactate in the blood appear to be uninfluenced unless peripheral circulation is improved concurrently.

Surgery may be required to eradicate a nidus of infection. As examples of this requirement, laparotomy may be necessary for a pelvic abscess, chorioamnionitis may compel induction of labor, and septic abortion may necessitate curettage and perhaps hysterectomy. One attempts to control the bacteremia before subjecting the patient to added stress, but sometimes bacteremia persists until an infected nidus is removed.

Vasoactive drugs have been used in an at-

tempt to restore circulating homeostasis, and thereby counter so-called irreversible shock, and to forestall renal ischemia and renal shutdown. There are two types of adrenergic receptors situated in the vascular system: alpha and beta. Alpha-adrenergic receptors mediate vasoconstrictor responses, whereas beta receptors mediate vasodilatation. Thus, levarterenol (Levophed) or norepinephrine and metaraminol (Aramine) cause vasoconstriction by stimulating alpha receptors in blood vessels and are referred to as alphamimetic drugs. These two drugs and angiotensin (Hypertensin) appear to be the vasopressor drugs that have been used most commonly in the recent past. Unlike levarterenol and metaraminol, the action of angiotension appears to be independent of adrenergic receptors.

Isoproterenol (Isuprel)[17] and mephentermine (Wyamine) cause vasodilatation by stimulating beta receptors and are referred to as betamimetic drugs. Phenoxybenzamine (Dibenzyline)[18-20] and phentolamine (Regitine) also cause vasodilatation, but by the mechanism of antagonizing vasoconstrictor effects; such alpha-adrenergic blockers (alpha-receptor blockers) are referred to as alphalytic drugs.

Proponents of the use of vasodilators in place of vasopressors point out that pallor, sweating, and tachycardia reflect vasoconstriction. They postulate that dilatation of blood vessels rather than their further constriction by vasopressors is required to relieve vascular pooling. Despite considerable discussion based on animal experimentation, there is a lack of data on the efficacy of vasodilators in the management of human victims of endotoxic shock.

A possible basis for the discrepancy in opinions regarding the use of vasopressors is that less than desirable results have been noted in patients whose state of shock has become profound before its recognition. Currently it is recommended that one initiate therapy with a vasopressor, but that if the patient does not respond to such management after a reasonable interval, use of a drug such as isoproterenol is to be considered. However, if endotoxic shock is not diagnosed early and adequate antibiotic therapy is not quickly initiated, no vasoactive treatment, vasopressor or vasodilator, will have optimal effect. It probably is unnecessary to raise the systolic blood pressure above 100 mm of mercury in a previously normotensive patient.

Oxygen therapy and hyperbaric oxygenation may be helpful in experimental animals, but the logic of their use in humans is disputed.

An airway is provided if necessary.

Digitalization is carried out only if the central venous pressure remains above 15 cm of water and particularly if other evidences of cardiac failure, such as pulmonary edema, are detected.

There are no exact data that elevating the foot of the patient's bed and applying an abdominal binder and leg bandages are of substantial benefit.

Hypothermia[21,22] may reduce the need for cellular oxygenation, but its exact application remains unclear.

Renal failure, which is partial or incipient, may be reversed by mannitol given intravenously. Hemodialysis has contributed to maintaining life and reducing morbidity during the oliguric phase of renal shutdown.

Use of analgesics, sedatives, and other depressants is best minimized.

Not all investigators advocate the routine use of adrenal glucocorticoids. A review of mortality rates in reported series wherein adrenal glucocorticoids were used has indicated that patients receiving them may have a higher mortality rate. Among objections to such therapy are impaired immune response, increased susceptibility to upper gastrointestinal bleeding, and fatal staphylococcal superinfection. It may be wiser to limit the administration of adrenal glucocorticoids in nonpharmacologic doses to those patients who had been receiving them before the occurrence of the infection.

The routine use of blood or its products is not advised, because in the usual case of endotoxic shock there appears to be no loss of blood, but rather the stagnation and faulty redistribution of blood. It would not appear wise to chance overloading an already distressed vascular system. However, recent hemodynamic studies indicate the need for some revision of the concept that blood volume should be expanded only to replace obvious losses. Shock may respond well to volume expansion when there is no demonstrable site for blood or plasma loss. Such functional deficits in blood volume are presumably related to intravascular or extravascular sequestration.[9]

A rapid intravenous infusion of low molecular weight dextran, in patients with a normal central venous pressure but low cardiac output and hypotension, appears to be relatively safe and may restore the circulatory dynamics without resorting to a vasopressor or a vasodilator.[23] Dextran-40 has only recently become commercially available in the United States.

Heparinization to counteract intravascular coagulation has been advocated, but its benefit lacks clinical confirmation. Numerous other regimens, including sympathetic block, alpha-aminocaproic acid, testosterone, aldosterone, serotonin antagonists, chlorpromazine, and even antihistaminics, have been described as being helpful in experimental animals, but this does not automatically assure their efficacy in the human subject.

Comment and Conclusions

The outcome is considerably determined by the severity of the underlying infection and the duration of shock before institution of appropriate management. Patients who recover usually have had the benefit of early diagnosis and treatment. To assure the best prognosis, potential candidates must be recognized and managed accordingly. Along with monitoring of the candidate's temperature and pulse rate, hourly determinations of the blood pressure and recording of the urinary output appear to be the best routine objective indices of the patient's current status. It is our experience, that when shock has become advanced, optimal response to therapy is less likely.

Empiric antibiotic therapy is begun when report of cultures is received or, in seriously ill patients, after blood has been drawn for cultures. If the patient's condition and microbiologic data later indicate that such empiric therapy is unsatisfactory, it is modified accordingly. Use of specific antibiotics in the initial management of bacteremia due to gram-negative bacilli is only theoretically possible, because one is often thwarted by lack of cultural proof of the pathogen and almost always of its [in-vitro] susceptibilities. However, these difficulties are not so great that adequate antibiotic therapy cannot be devised on an empiric basis. If such a regimen is not employed, or not employed early in the infection, the essential problem is not being attacked and recovery is unlikely. Supportive therapy is designed only to maintain the patient's life until antibiotic therapy can control the overwhelming infection which is the essential cause of the vascular collapse.

To the present, most patients at the Mayo Clinic with endotoxic shock have received a vasopressor and antibiotic therapy; they have not received adrenal glucocorticoids. At the same time, evaluation and modification of the regimen are made; these include assessment of isoproterenol (Isuprel) as an antihypotensive drug and the rapid infusion of dextran in place of a vasoactive drug in selected patients.

Although pertinent antibiotic therapy and reasonable supportive measures can improve the survival rate among victims of endotoxic shock, certain sequelae of the infection can occur. Chávez Castro and his co-workers[24] have commented on these, including those related to fertility, menstrual abnormalities, and those that may complicate future pregnancies, such as abnormal implantation of the placenta, ectopic pregnancy, and uterine rupture.

Experience

Some doctors make the same mistakes for twenty years and call it clinical experience.—Noah Fabricant

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

Conventional Radiography

The restless duodenum makes radiographic diagnosis difficult, uncertain and often unproductive: Is this duodenum abnormal?

Hypotonic Duodenography

Pro-Banthīne-induced duodenal calm permits full anatomic appraisal: Same patient. Duodenal normality is now evident.

- **in diagnosis**
- **in treatment**

Pro-Banthine® brand of propantheline bromide

calms the gastrointestinal tract

For fifteen years Pro-Banthine has been the most widely used anticholinergic agent in disorders of gastrointestinal motility and gastric hypersecretion. More recently Pro-Banthine has reestablished its pharmacologic effectiveness in diagnostic procedures using intragastric fibroscopy and hypotonic roentgenography.

How the X-rays were taken

In the hypotonic duodenograph[1,2] reproduced above, the gastrointestinal tract was relaxed with Pro-Banthine. The duodenum was intubated. Pro-Banthine in a dose of 60 mg. intramuscularly was used to assure prompt aperistalsis and double-contrast visualization was achieved with ordinary barium and air.

The same pharmacologic efficiency has proved of pronounced value in such conditions as: *peptic ulcer, pylorospasm, biliary dyskinesia, functional hypermotility and irritable colon.*

Contraindications: Glaucoma or severe cardiac disease.

Precautions: Since varying degrees of urinary hesitancy may occur in elderly males with prostatic hypertrophy, this should be watched for in such patients until they have gained some experience with the drug. Although never reported, theoretically a curare-like action may occur with possible loss of voluntary muscle control. Such patients should receive prompt and continuing artificial respiration until the drug effect has been exhausted.

Side Effects: The more common side effects, in order of incidence, are xerostomia, mydriasis, hesitancy of urination and gastric fullness.

Dosage: The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthine (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg. The parenteral dose should be adjusted to the patient's requirement and may be up to 30 mg. or more every six hours, intramuscularly or intravenously.

SEARLE

Research in the Service of Medicine

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

Irradiation and the Fetus*

OVER THE PAST 20 years there has been an increasing awareness of the hazards of radiation. In an article in the August 1967* issue the reader's attention is focused on the value of diagnostic radiologic procedures compared to the potential damage to maternal and fetal gonads and hence to generations as yet unborn. Although the reader quickly senses that this problem is a complex one, the author's summary of the currently available data provides sufficient background information to allow the radiologist and obstetrician to weigh the potential risks of radiation exposure during pregnancy with the value of the proposed procedure. In this comparison, however, the reader should consider the roentgen exposures shown in the tables as maximum, because some of these data were collected without an attempt to reduce radiation doses to the absolute minimum.

The author discusses the radiological procedures used in two common obstetrical problems—cephalopelvic disproportion and placental localization. He recommends the replacement of older diagnostic radiation techniques still widely used in these two problems with modified or newer approaches that reduce radiation exposure of the maternal and fetal gonads without sacrifice of accuracy. At the present time x-ray pelvimetry offers the only method by which cephalopelvic disproportion can be accurately assessed. Although many techniques have been described for measuring the pelvis, the exposure of the maternal and fetal gonads and fetal total body radiation from x-ray pelvimetry remain significant. Exposure can be reduced not only by reduction of views from four or three to two as the author suggests, but also by the employment of other refinements of radiation technique such as proper coning, filtration of the beam, proper positioning of the patient to minimize the need for repeat films, the use of high kilovoltage, high speed screens and films, long tube to film distance and rapid developing solutions. All of these measures further reduce the radiation needed for quality radiographs.

The value of placentography in the management of suspected placenta previa is probably greatly overrated. No technique yet described is 100% accurate. Unlike cephalopelvic disproportion most suspected cases of placenta previa can be managed adequately without maternal or fetal exposure to radiation. If fetal maturity has been reached when the problem presents itself, direct digital examination for the placenta is the preferred method of diagnosis. This examination is done with facilities ready for abdominal delivery if immediate interference is necessary. If the infant is of premature size, expectant treatment is followed. It is academic to locate the placenta by radiologic means, because the expectant management of the problem is not altered. If

the clinician believes that exact location of the placenta is important, radiation exposure of mother and fetus is drastically reduced by the relatively new and fairly accurate technetium Tc99m serum albumin technique.

Clinical judgment and the use of non-radiologic means now available to the clinician, such as amniocentesis, determination of maternal urinary estriol excretion, fetal electrocardiography and ultrasound, have reduced or eliminated the need for radiologic techniques in the evaluation of some of the other clinical obstetrical problems mentioned but not discussed in the article, such as fetal maturity, excessive uterine enlargment, and suspected fetal death.

Non-obstetric radiologic diagnostic procedures during pregnancy are permissible if clearly indicated. The uterus and fetus can be shielded from direct radiation and the number of films can be reduced. Unintentional significant irradiation of the early pregnant uterus during the critical time of organogenesis can be prevented if all radiological examinations are done within 10 days after onset of a normal menstrual period or time is taken by the radiologist to ask appropriate questions and by the clinician to perform necessary examinations to eliminate the possibility of early pregnancy.

Implantable Cardiac Pacemakers

ATRIOVENTRICULAR DISSOCIATION (heart block) disrupts the reflex pumping function of the ventricle with secondary results of heart failure, Stokes-Adams syndrome, and often death. Other than those surgically induced, most heart blocks follow a major or minor coronary artery occlusion. The monitoring experience of coronary care units indicates that many heart blocks are transient episodes of partial to complete atrioventricular dissociation interspersed with other cardiac rhythms. Unfortunately a single episode may result in cerebral anoxia and death.

The physician now has an effective temporary or permanent apparatus to aid the patient and prevent the unfavorable sequelae of heart block. The intravenous pacemaker unit (external or internal battery) can be rapidly inserted through a peripheral vein. *No* patient is too ill for this procedure if the cardiac indications are present. In emergency, temporary percutaneous transmyocardial electrodes are effective.

The benefits of the electronic pacemaker units have been well documented in clinical and laboratory studies.*

Electronic failure and complications are infrequent.

Patients with long-standing complete heart blocks, incapacitated by recurrent attacks, syncope, convulsions, and heart failure, may be physically rehabilitated. In acute states, especially early block in the course of myocardial infarction, the pacemaker may be used temporarily and removed when physiologic connections are re-established. In lesser degrees of block or with variable block there is a problem of competition between the impulse of sinus origin occasionally firing the ventricles, and the steady stimulation of the inserted pacemaker. In such a situation demand pacemakers are available, ingeniously designed to suppress pacing when the ventricular beat is otherwise stimulated—an electronic compensatory pause. When any degree of heart block appears in the course of acute myocardial infarction, probably the safest procedure today is to insert a transvenous pacemaker into the right ventricle, connecting it to an external pacemaker as required. If the block becomes permanent the pacemaker can be implanted. If not, the intracardiac electrode may be removed when conduction returns to normal.

The subcutaneous unit does not impair physical activity, bathing, etc. and is stable for two to three years before a battery change is needed. Availability is nationwide. Every patient with transient or complete heart block should be carefully evaluated for such electronic help.

Diagnostic Use of Liver Biopsy

Doctors Knutson and Miller* have stressed the ease and safety with which the Menghini technique of needle biopsy of the liver was accomplished by "inexperienced physicians" in 59 patients. Without necessarily taking exception to their conclusions, I think that the implications of their report warrant comment, and some closely related considerations deserve emphasis.

The authors stated that utilization of diagnostic liver biopsy has been limited because of the skill required and because of the significant morbidity with use of the Vim Silverman needle. Other factors being nearly equal, if morbidity and mortality can be reduced by using the Menghini technique, then this method certainly would be preferable. The main disadvantage attributed to the Menghini needle is a relatively high failure rate in obtaining tissue from fibrotic livers. However, as yet, controlled studies of the relative merits of the two procedures have not been reported.

If, in fact, utilization of liver biopsy has been limited, this is perhaps more likely (certainly more ideally) to be related to a better general understanding of the indications, contraindications, and limitations of interpretation of liver biopsy.[1] These latter considerations are clearly more important to stress to inexperienced physicians than the relative ease with which the procedure can be performed.

Among patients with liver disease, biopsy of the liver is helpful for diagnosis in a relatively small proportion of cases. With intelligent selection of patients and critical use of the procedure, it is indeed simple, safe, and reasonably accurate with *either* the Menghini or the Vim Silverman technique.[2] More important than the type of needle is the experience of the operator and his familiarity with the technique he is using. The diagnostic success reported in any series depends primarily on the indications for which the procedure was employed and the experience of the pathologist interpreting the morphology of the specimens.

The Cytologic Detection of Preclinical Carcinoma of the Uterine Cervix

During the past 20 years the cytologic detection of preclinical carcinoma of the uterine cervix through the routine use of cervical smear techniques has become a well-established laboratory procedure. This method of cancer detection, when first introduced, was not readily accepted by the pathologist or the clinician as a reliable or practical method of screening large numbers of asymptomatic women. However, once the pathologist became convinced of its value and the "modus operandi" was established, most clinicians were quick to seek out laboratories that offered this service. This fact is well substantiated by figures given in an article appearing in the January issue of Minnesota Medicine.* It is indeed creditable that 99 physicians from 28 regional centers in and around Duluth are screening nearly 12,000 women each year.

The numerical method of expressing the findings in a smear is fairly well standardized from laboratory to laboratory, but it is im-

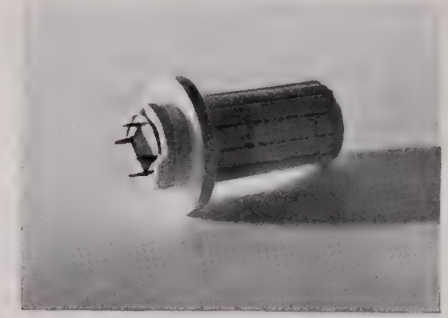
portant that a clear understanding exist between clinician and pathologist with regard to the significance of this method of reporting. Over the years, at the Mayo Clinic, about 50% of the class III smears have revealed carcinoma. Class II smears are rarely reported, and when they are it is because of extenuating circumstances or a situation in which the patient is easily accessible for a follow-up smear in order to detect the possible appearance of cells that in our opinion warrant tissue diagnosis. Individual interpretation of cell characteristics varies, so that some observers might choose to consider some of our class III smears as class II and recommend that repeat smears be taken at given intervals to determine whether or not progressive changes in the exfoliated cells make tissue diagnosis advisable. More than 90% of our cases in which a class III smear failed to reveal carcinoma in the cervical-cone biopsy showed varied degrees of epithelial dysplasia. Such dysplasia, in our opinion, is foreboding and should be eradicated as a preventive measure. The fact that over 40% of the carcinomas discovered in our laboratory were detected on class III smears serves to emphasize the close association of epithelial dysplasia and carcinoma, rather than a "hedge" by the pathologist in diagnosis. Extensive involvement of the junctional zone with carcinoma almost always yields a class IV or V smear.

As is stated elsewhere in this issue, the smear has no role in diagnosis of clinically obvious carcinoma of the cervix. In this situation, primary biopsy is the procedure of choice. In lesions of borderline significance, however, the smear may complement the biopsy, since occasionally the smear will reveal a carcinoma that has been missed at biopsy—even by an experienced examiner. Cauterization of the cervix should be delayed until after negative results of smear and biopsy have been received, since there is a risk of having the results of the cytologic study positive and having a patient with a partially denuded cervix that is not suitable for a reliable cone biopsy. Preclinical invasive carcinoma (microinvasive) has been found in about 10% of carcinomas detected by smear. This figure varies from one laboratory to another because individual interpretation varies in difficult cases involving borderline decisions.

The use of cervical conization as a therapeutic measure as well as a diagnostic tool is debatable. In those situations wherein excised cones can be immediately processed by reliable fresh-frozen sections to assure that the apex and base of the cone are free of carcinoma and it is assured that the patient will submit to a careful follow-up program, there should be no objection to employing conization in such a dual role.



When in-situ carcinoma of the cervix is treated, three important facts must be remembered. (1) Extension of in-situ carcinoma onto the vaginal cuff occurs in a significant number of women. (2) In-situ carcinoma in 1 to 2% of affected women is multicentric in origin on the cervix or the cervix and vagina. (3) There is a tendency for the late occurrence of vaginal or even vulval carcinoma in women who at one time had in-situ carcinoma of the uterine cervix. Routine examination and vaginal smears then are mandatory, probably for the rest of the patient's life, irrespective of conization or simple hysterectomy as a mode of treatment. In addition, the age of the patient with respect to childbearing and the possible need for pelvic reparative surgery probably should be considered.

Excessive cost of case discovery has long been a "selling point" of those opposed to routine screening of asymptomatic women. For those women whose cancers have been discovered by smear, especially those with early invasion, this line of reasoning seems a little incredulous, particularly in light of the great sums being expended on esoteric medical research. The $787 expended in the Duluth area for the detection of a single carcinoma would appear to be money well spent. As the number of women in whom yearly smears are taken increases, the case-discovery costs may conceivably show an upward trend because, as the repeat smear population grows, the overall detection rate will diminish. However, with ever-increasing numbers of women being screened, the cost base broadens and the individual "insurance rate" remains the same.

Hostile Dependency in Marriage

WHY DO TWO people marry each other? All too often the answer is a mix of neurotic needs —complementing each other's unconscious, unresolved conflicts. Of course, many such marriages end in divorce, but more often the very factors that attracted the partners to each other hold the marriage together. The problems take many forms, but emotional immaturity almost always is a factor. Associated with such immaturity is a selfish, demanding, and pathologically dependent person. Hypertrophied dependency needs, a residuum of frustrated needs from childhood, suffocate the mutual give-and-take that a resilient, healthy, intimate relationship entails. With the inevitable development of problems in marriage, often accentuated by the demands put upon an emotionally immature woman with a growing family, old neurotic defenses tend to falter and new ones arise. The loss of self-esteem, the giving up of ideals of what marriage previously was believed to offer, a breakdown in communication between the partners, and the development of physical symptoms and bodily changes which bring about a realization of aging with a loss of vitality often result in frustration, bitterness, and anger which is either internalized or projected with resultant depression or paranoid ideation. Suspicions of the husband replace angry tirades involving the wife's own inabilities and eventually drive the couple to the point of no return with wounds that refuse to heal. Carter* has described this "paranoid wife syndrome" quite well.

When the physician sees such an angry, hostilely dependent woman with somatic symptoms, who also may have evidence of depression and paranoid ideation**, it is important that the evaluation also include the husband. Nothing can replace a thorough evaluation of the problem from all aspects in order to make the best effort toward resolution of the situation.

Therapeutic endeavors can be quite frustrating to the physician, especially when a hostile-dependent relationship is transferred to the doctor. Such problems must be handled individually, and as Dr. Carter has pointed out, multiple solutions can be effected; but it is important to realize that the physician, who often is caught between the spouses in the marital struggle, must remain objective and point out possible solutions without being judgmental or an advice-giver.

The Editor's Soliloquy

Paul Revere Bowl—The St. Barnabas Bowl

"Listen my children and you shall hear
Of the midnight ride of Paul Revere."

That famous ride made Paul Revere immortal in national legendary. In the American imagination he still gallops on the road to Lexington.

But as a product of our Revolutionary era he was far more than patriot: instigator of resistance and communal speaker for independence. He was, in addition, one of the most ingenious and versatile craftsman this country can point to with pride and distinction. His innate and irresistible creativity demanding expression doubtless contributed to Revere's phenomenal achievement.

Within the field of medicine Revere's notable civic activities included the Presidency of Boston's first Board of Health and the office of Coroner for Suffolk County, and though he demonstrated no other talent in the field of medicine or surgery his early cognizance of the deplorable condition of Bostonians' teeth induced him to practice restoration dentistry for a while. Appearing in the Boston Gazette his advertisement claimed: "He has fixed some Hundred of Teeth and he can fix them as well as any Surgeon-Dentist who ever came from London, he fixes them in such a Manner that they are not only an Ornament, but of real use in Speaking and Eating; He cleanses the Teeth and will wait on any Gentleman or Lady at their Lodgings, he may be spoke with at his Shop, where the Gold and Silver smith's Business is carried on in all its Branches." However, Revere soon lost interest in improving defective dentition and abandoned the field, despite its lucrative prospects.

After the war Revere conducted a retail business in his shop; with Yankee shrewdness he realized that a nice profit could accrue from importing and selling articles that were scarce in Boston: hardware, paper products, Sheffield plate, drygoods and notions, and eyeglasses. He was also co-founder and president of the Massachusetts Charitable Mechanics Association and one of the original incorporators of the Massachusetts Fire Insurance Company.

As metallurgist Revere pioneered and innovated in such substances as iron, copper, gold, and particularly silver. In his own mill he produced copper fittings for boats and ships and, subsequently, copper sheathing for their hulls. The Constitution, the Essex, and over twenty other ships were assembled with copper fastenings from the Revere mill; and later Old Ironsides received a new copper hull from the same mill.

Then there were bells! Where Revere mastered the principles of such a technical process as bell casting—with its esoteric secrets of assaying and moulding—remains a mystery. Of the Revere output there remain extant in New England today some 75 fine bells, unimpaired in structural and tonal excellence and beauty. Incidentally, the bell of the Constitution, shot away in action, was a Revere product.

Above all, Revere was a paragon in silversmithing, the craft he had learned from his father. Under his magic touch there materialized chafing-dishes, urns, coffee and tea pots, pitchers, porringers, and bowls—all functional in design and pre-eminent for their elemental strength, simple dignity, intrinsic symmetry, and exquisite luster.

Designed on the lines of Chinese porcelain bowls, Rever's Liberty bowl, one

of his handsomest pieces, was a gallon-capacity punch bowl fashioned in honor of the seventeen members of the Massachusetts General Court who voted not to rescind the circular letter sent to the other colonies in opposition to the Townshend duties on imports.

Many of the finest examples of Revere's craftsmanship in silver are exhibited in the Boston Museum of Fine Arts—to astonish and captivate the eye and mind of the beholder.

Can you now understand why I feel so humbly thrilled and honored to have received the sterling silver replica of Paul Revere's Liberty Bowl: the Saint Barnabas Bowl! From the bottom of my heart, I thank you.

—Carl O. Rice, M.D.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Curbstone Consultation

Babinski Reflex

QUESTION: Is it possible to fake a Babinski reflex?

ANSWER: It is possible for a person who is familiar with the details of a Babinski reflex to produce a false positive result providing that he can overcome the withdrawal reflex.

Diphtheria-Tetanus

QUESTION: What is the route for giving diphtheria-tetanus combined to individuals after the age of 40 years?

ANSWER: Diptheria-tetanus toxoids combined is available in a special preparation for adult use and is given intra-muscularly. The recommended schedule consists of two injections of 0.5 c.c., one to six months apart, followed by a booster injection every five years.

Heart Attacks

QUESTION: Can persons who have had heart attacks return to moderately hard work?

ANSWER: About two-thirds of all patients who have had a heart attack are able to go back to their original degree of physical activity — or to a schedule a little below. Nevertheless, it is inadvisable to allow any person who has had a heart attack to return to an extremely strenuous occupation — anything for instance, that requires heavy lifting, straining or a great deal of hurry.

It is interesting to note that much has been learned about energy requirements of different types of occupations. Many of the positions that were formerly considered to have great energy requirements have been found to be much less demanding than originally thought. Nowadays, many factory workers spend much less energy per day than the average housewife.

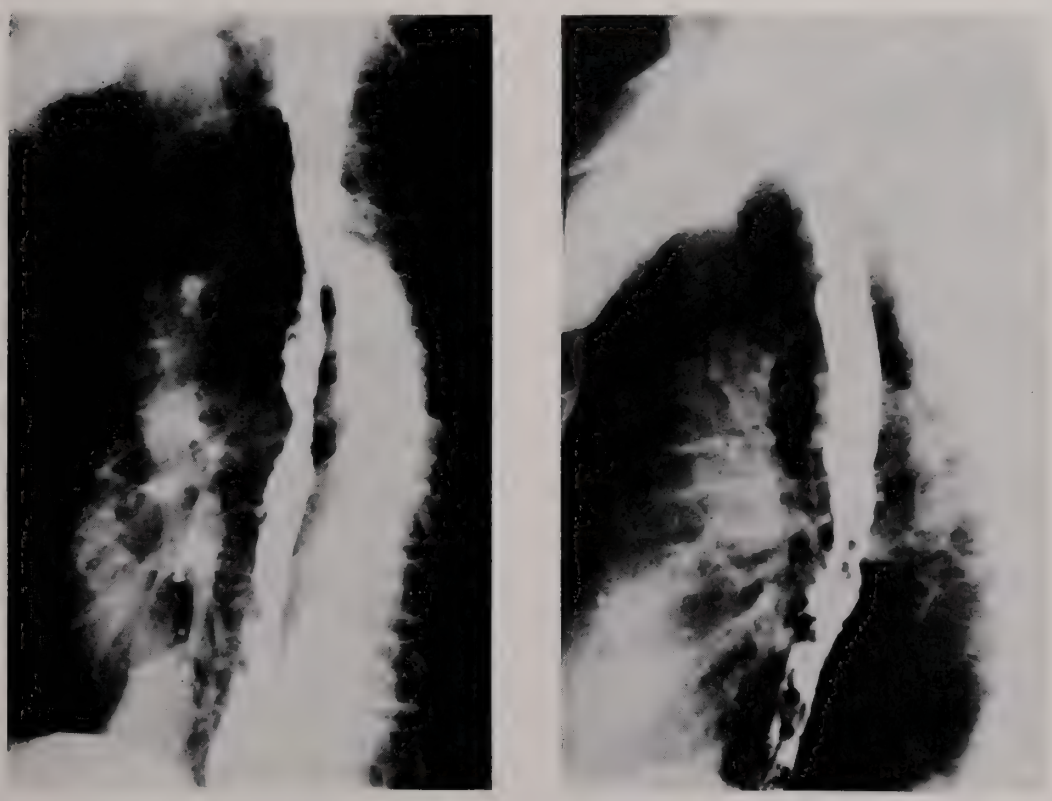
Dysphagia and Substernal Pain in a 62-Year-Old Man



THIS 62-YEAR-OLD construction worker was referred to the University of Minnesota Hospitals with a chief complaint of pain on swallowing for several months. The pain was described as a burning, substernal sensation relieved by antacids and aggravated by swallowing both solids and liquids. The patient had lost weight. He had gone to his local physician one month prior to admission here after vomiting some bloody material. He gave no history of liver disease, although he admitted to "moderate" alcohol intake over many years.

General physical examination was unrewarding. Liver studies were normal.

Esophageal fluoroscopy revealed a very diffuse pattern of irregular, nodular filling defects extending from the cervical esophagus to the diaphragm (Figure) with little peristalsis apparent.

Esophagoscopy showed "large soft polypoid projections of mucosa" projecting into the lumen throughout the thoracic esophagus except for the very terminal portion. The mucosa over the "polyps" was intact, and their softness "did not suggest malignancy" to the examiners. Their impression was "diffuse polyposis of the esophagus." Multiple biopsies were taken.

What is your diagnosis? (See next page.)

Oblique Lateral

Figure

Diagnosis: Squamous Cell Carcinoma of the Esophagus.

Comment

The usual squamous cell carcinoma of the esophagus enlarges locally, frequently constricting and eventually obstructing the esophagus while still involving a relatively short segment. While it is well known that spread of the lesion mucosally or submucosally occurs very frequently beyond the site of the gross lesion, the extent of this spread is usually not apparent on esophagus films.

In a recent report, Minielly, Harrison, Fontana, and Payne describe an entity called "verrucous squamous cell carcinoma of the esophagus," a variety of carcinoma which tends to be exophytic in its growth pattern. While locally invasive, it tends to grow as a large mass within the esophagus and metastasizes rarely or late.[1] The tumor is thought to be similar to verrucous squamous cell carcinomas found much more commonly elsewhere (nasal and oral cavities, larynx, vagina).[2] Because of the different growth pattern, Minielly et al. felt early recognition and surgical treatment offered these patients a better chance for survival than the patient with the usual esophageal carcinoma. While the present case may or may not fit all the criteria for this morphological variant, it obviously spread mainly intrinsically as an exophytic, papillary growth, becoming very extensive before causing symptoms.

Differential diagnosis from the films might include esophageal varices,[3] and monilial esophagitis, which may produce gross irregularities in the barium swallow over the entire esophagus.[4] Leiomyomata, bulky adherent mediastinal lymph nodes, etc. may produce multiple defects in the barium column,[5] but should be more easily differentiated from the unusual squamous cell carcinoma presented here.

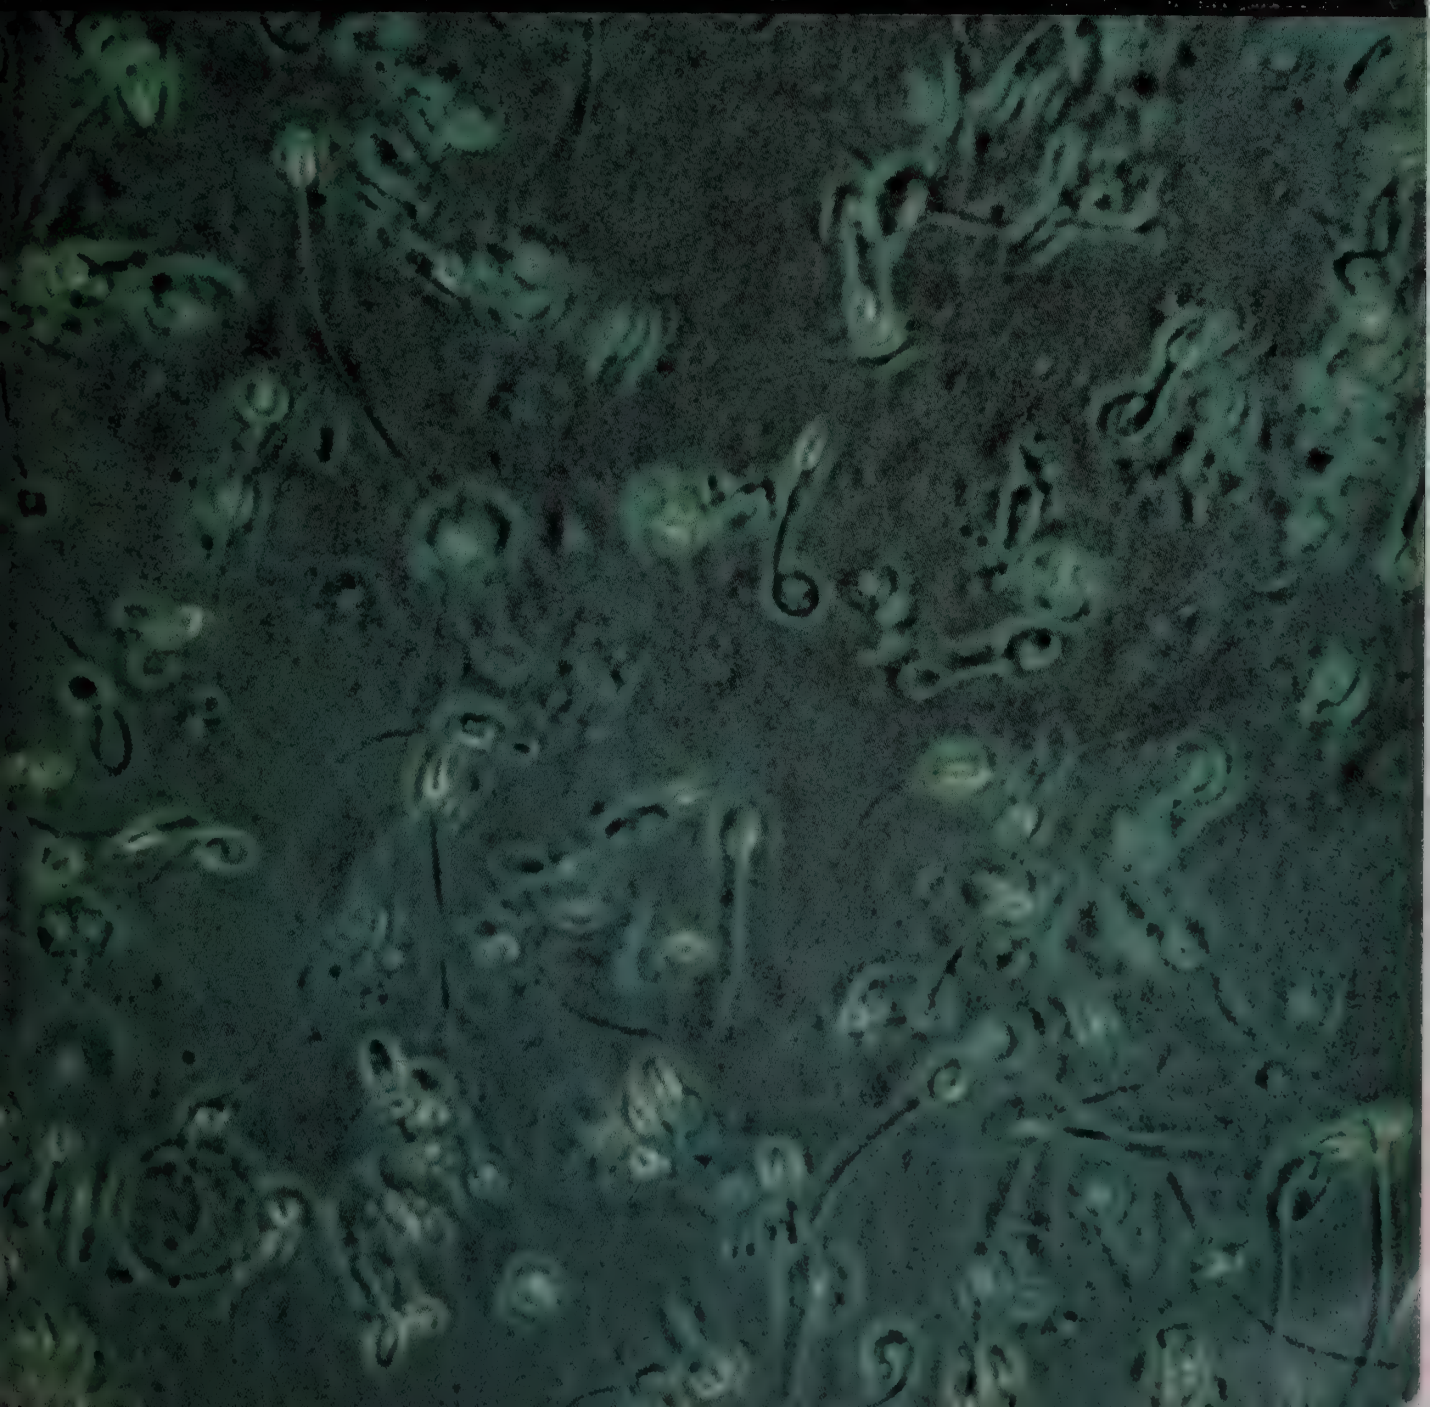
Dowieism



About 1900 Alexander Dowie announced that he was the prophet Elijah returned to earth, although without a chariot. He healed by the laying on of hands. His system was obviously faith healing. As a promoter Dowie was no doubt second only to Mrs. Eddy in this country. He built up a large following, established a city with tremendous industries and established church observances and ritual sufficient to occupy the minds of those who followed him. Like other prophets of healing he thundered against physicians and attacked preventive vaccination. When he passed on, the holy robes succeeded to Glenn Wilbur Voliva, now the czar of Zion City, the Jerusalem of the cult. Voliva thinks the world is flat.*

*Morris Fishbein, M.D.: The New Medical Follies, 1927.

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl®-1.

(norethindrone 1mg. & mestranol 0.05mg.)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of NORINYL-1 (norethindrone 1 mg. with mestranol 0.05 mg.) in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with NORINYL-1. Therefore, if such tests are abnormal in a patient taking NORINYL-1 it is recommended that they be repeated after the drug has been withdrawn for two months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibromyomata may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. 5. NORINYL-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, and as in all cases of irregular bleeding *per vaginam*, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged NORINYL-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving NORINYL-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. 11. Because of the effects of estrogens on epiphyseal closure, NORINYL-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with NORINYL-1 may mask the onset of the climacteric. 13. The pathologist should be advised of NORINYL-1 therapy when relevant specimens are submitted.

Side effects observed in patients receiving oral contraceptives: The following adverse reactions have been observed in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression.

Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation post-treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption, itching.

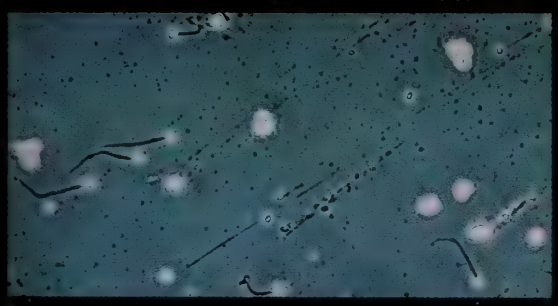
The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has been neither established nor disproved): thrombophlebitis, pulmonary embolism, neuro-ocular lesions.

The following laboratory results may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, Factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from

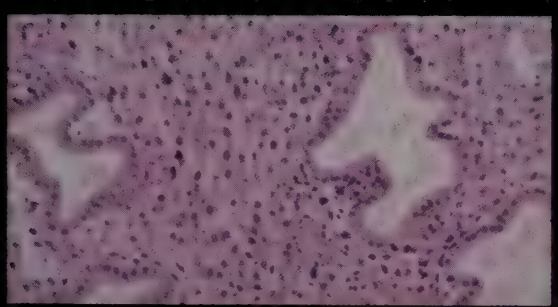
SYNTEX

LABORATORIES INC., PALO ALTO, CALIF.



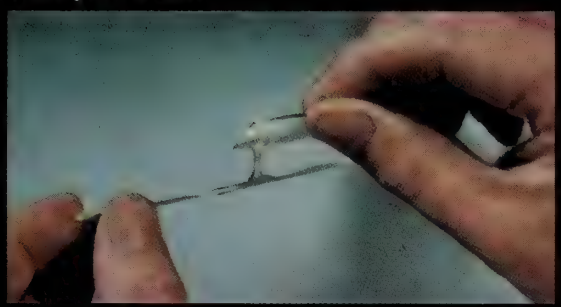
Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation. These effects are illustrated below.

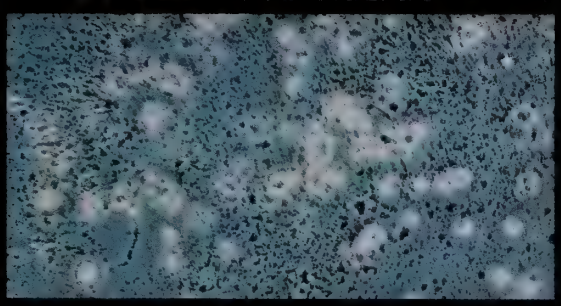


Untreated Patient

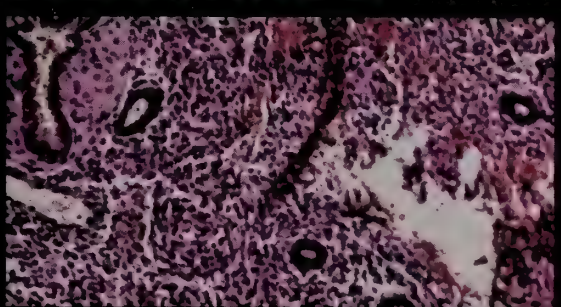
Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.



Spermatozoa appear healthy, active, freemoving.



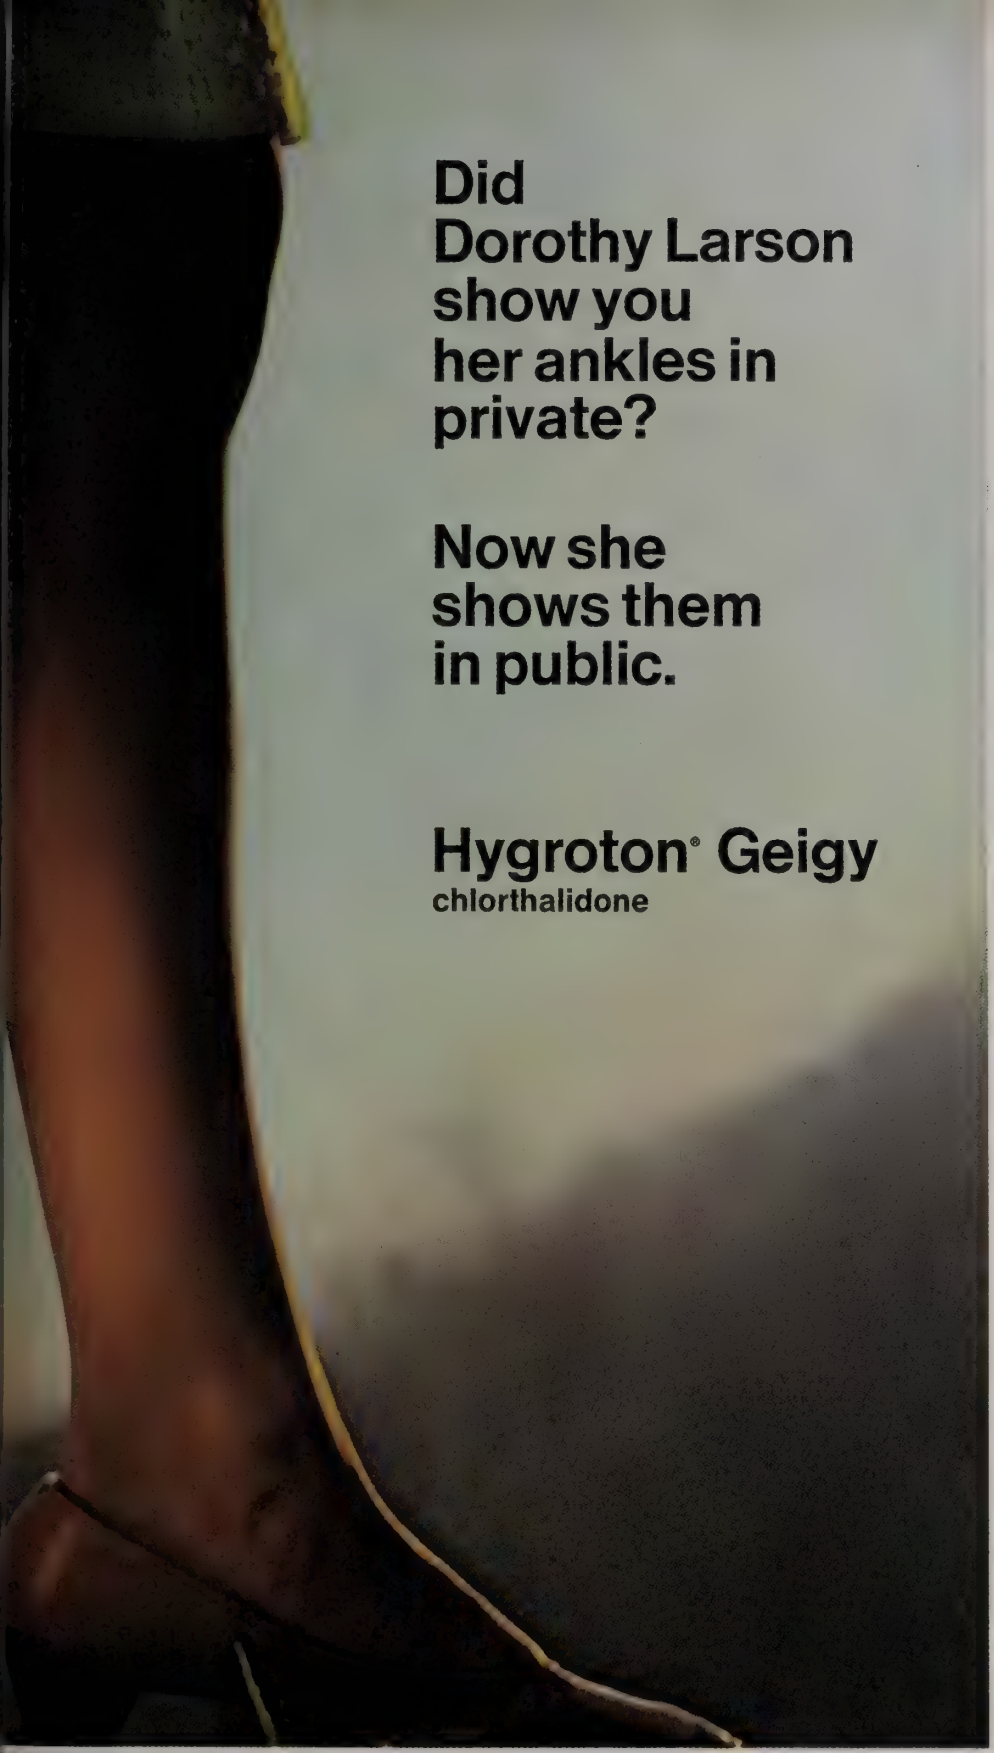
Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.



Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.



Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl®-1 tablets
(norethindrone 1mg. & mestranol 0.05mg.)

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

Indications: Hypertension and many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Use with caution in pregnant patients, since the drug may cross the placental barrier and adverse reactions which may occur in the adult (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.
Precautions: Antihypertensive therapy with Hygroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents or other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Barbiturates, narcotics or alcohol may potentiate hypotension. Because of the possibility of progression of renal damage, periodic determination of the BUN is indicated. Discontinue if the BUN rise or liver dysfunction is aggravated. Hepatic coma may be precipitated Electrolyte imbalance, sodium and or potassium depletion may occur If potassium depletion should occur during therapy, Hygroton shou be discontinued and potassium supplements given, provided the

Did Dorothy Larson show you her ankles in private?

Now she shows them in public.

Hygroton® Geigy
chlorthalidone

Your office examination confirmed Mrs. Larson's ankle edema.

You prescribed Hygroton—to get rid of the edema.

And you found that Hygroton is not only effective; it frequently costs less than other equivalent therapy.

A nice way to treat the Mrs. Larsons in your practice.

Hygroton therapy may mean troublesome side effects for some patients. A summary of the prescribing information is shown below.

patient does not have marked oliguria.
Take special care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, hyperuricemia, headache, muscle cramps, orthostatic hypotension, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.
Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.
Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

HY-5576R

Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.
Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

With Novahistine LP tablets and Novahistine Singlet™ tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.

Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever. Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.

Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.

Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

"Nothing else I've tried seems to work, so I decided to give you a crack at it."

Tumor Conference

Insulin-Secreting Tumors of the Pancreas

LOCALIZATION OF lesions in the pancreas is a much needed advance in preoperative evaluation of pancreatic tumors, particularly for small tumors such as insulinomas which are often difficult to locate at surgery. Recently, there has been increasing use of selective arteriograms for demonstrating lesions in many areas of the body. The following case report describes the use of pancreatic arteriography in the preoperative localization of a 1.5-cm. insulinoma.

Case Report

A 25-year-old white male was admitted to the Veterans Administration Hospital with a three-month history of episodes of weakness, disorientation and bizarre behavior, which usually occurred in the morning. He recalled these episodes poorly, but did remember that he sought candy for relief. He gave no history of sweating, tachycardia or nervousness. On the day of admission to the emergency room of another hospital, the patient had become unconscious. A blood sugar drawn at this time was reported to be 23 mgm %. On admission to our hospital, the patient appeared healthy but was less alert than normal with a somewhat obtunded sensorium. Physical examination was normal.

Laboratory studies were also normal with the exception of the glucose tolerance test. The following values were obtained: fasting value 52 mgm%; 30 min., 116 mgm%; 1 hr., 123 mgm%; 2 hrs., 132 mgm%; 3 hrs., 120 mgm%; 4 hrs., 60 mgm%; 5 hrs., 50 mgm%; 6 hrs., 30 mgm%.

Selective superior mesenteric and celiac arteriograms were performed. An increased area of vascularity was noted in the mid portion of the gland (Figure 1). During the preoperative evaluation, the patient had frequent administration of oral glucose except when special studies were performed. He experienced no more hypoglycemic episodes and demonstrated normal behavior.

The patient had an exploratory laparotomy six days after admission. Located in the proximal portion of the tail of the pancreas was a 1.5-cm. nodule which presented on the surface as a wine-colored nodule of approximately 0.5 cm. The true size of the lesion was appreciated as it was shelled out. On cut section, the tumor was pale yellow. The remainder of the gland was carefully inspected and palpated, and no further nodules were found.

Following surgery, the patient made a satisfactory recovery. Repeated blood sugars were all in the normal range. He has returned to work and has had no return of symptoms.

Discussion

Several aspects of this case are worthy of note. It is a relatively rare tumor. The largest series is that collected by Howard, et al.,[3] which consists of a survey of the literature and includes 361 localized tumors, 200 of which were operated for hyperinsulinism, and 161 discovered at autopsy. In

this and other series, the generally reported incidence of multiple adenomas is approximately 10%. Ten percent may also be carcinomatous.

The diagnosis of insulinoma can most surely be made in a patient demonstrating Whipple's triad: (1) symptoms of insulin shock frequently induced by the fasting state or during exercise, (2) repeated fasting blood sugar levels below 50 mgm%, (3) relief of symptoms by administration of glucose. Attacks may occur daily or once or twice a year for several years. Other helpful tests include a fasting tolerance test, which usually lasts for 12 to 36 hours. During this time, any symptoms of insulin shock are watched for and a blood sugar drawn. Exercise during this fasting period may provoke a typical hypoglycemic attack in a shorter period of time. In any case, the *sine qua non* is a return of symptoms with a documented glucose level of less than 50 mgm%.

Once surgery has been decided upon, preoperative knowledge of the exact location of the tumor is extremely helpful, since the tumors are distributed equally in the head, body, and tail. Careful mobilization and palpation of the entire gland will usually disclose the location of the tumor nodule. The majority are encapsulated and measure between 1.0 and 3.0 cm. They can

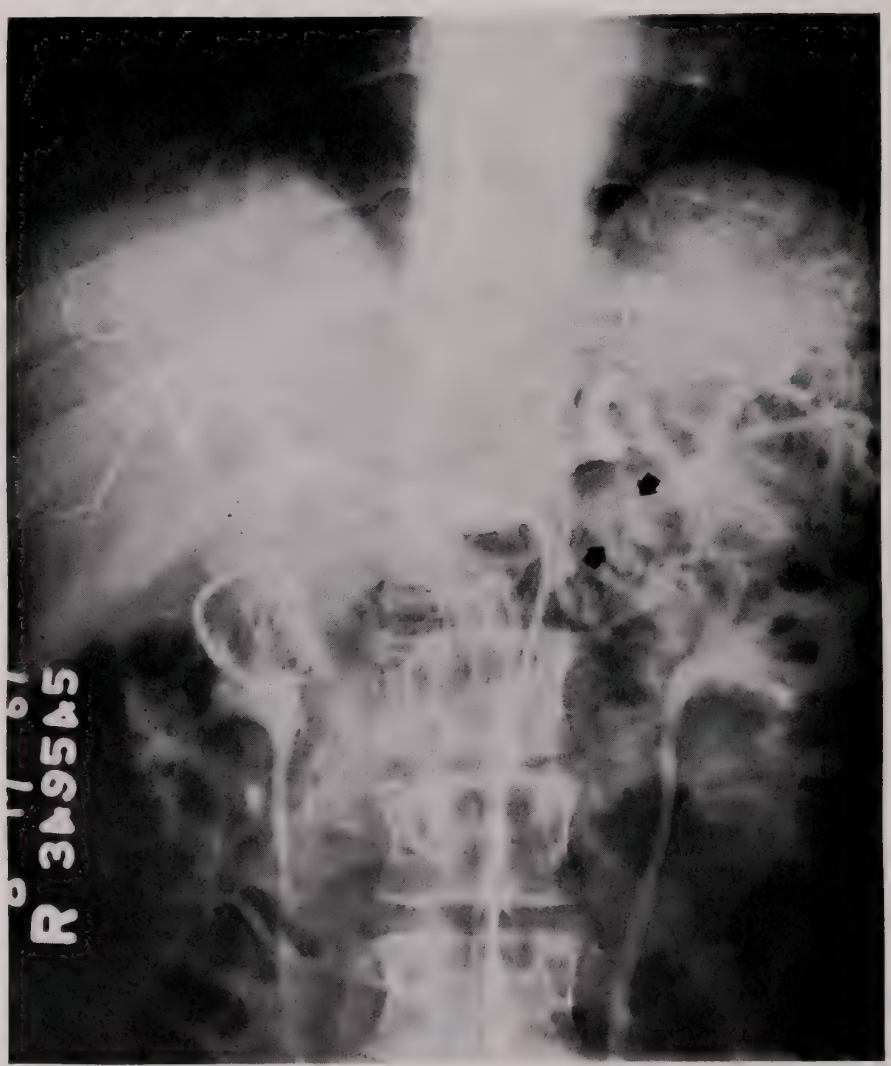

Fig. 1—Pancreatic arteriogram—catheters are visible in the celiac and superior mesenteric arteries. Increased tumor stain is seen between arrows.

be shelled out, although location or size may require resection of the pancreas. If no tumor is found, some recommend a "blind" distal pancreatectomy.[1,2] Howard et al.[3] found this to give a satisfactory therapeutic result in 46% of 56 patients. Recently, Miller[4] and Fonkalsrud et al.[5] have questioned the advisability of such an approach and, in fact, suggest that an occult tumor may more likely be in the head of the gland rather than in the tail.

Preoperative selective pancreatic angiography has been recommended to obviate some of these problems at the time of surgery. The use of angiography for the diagnosis of insulinomas was first reported by Olsson in 1963.[6] Dye injected simultaneously into the hepatic and superior mesenteric arteries demonstrated an islet-cell adenoma 1.5 cm. in diameter in the head of the pancreas. Baun et al.[7] identified four islet-cell tumors by angiography. The success of this study, however, depends on the vascularity of the tumor, i.e., whether the dye will stain the area. In six cases of insulinoma reported by Brookstein and Oberman,[8] the tumor was visualized by arteriogram in only two. Histologically these tumors show wide variability with regard to vascularity and will stain best if comprised of dilated blood-filled sinusoids. In reviewing other slides, this type of histological picture was found some-

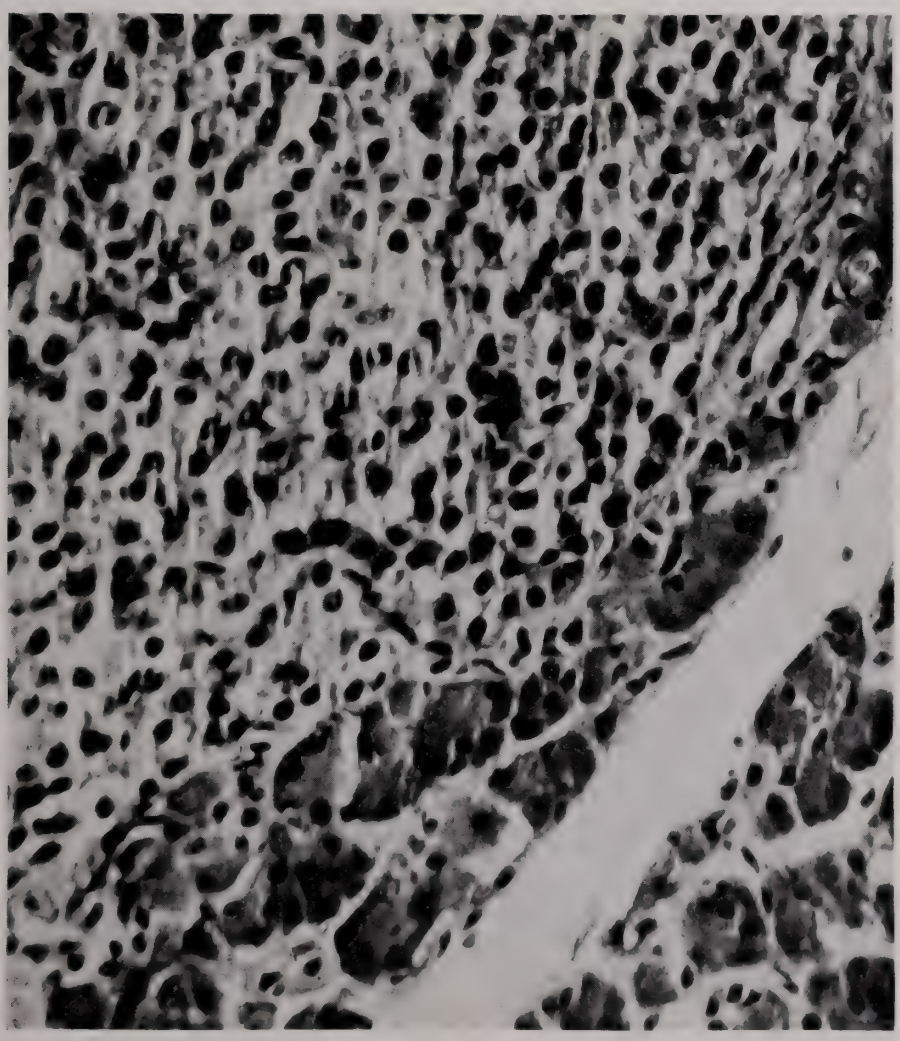

Fig. 2—Histology of tumor—Note homogeneous appearance without marked vascularity. A small amount of normal pancreatic tissue is visible. (Hematoxylin and eosin stain x 200).

what less than 20% of the time. The authors predict, therefore, that in only 20% of insulinomas will a tumor stain be identified. Nevertheless, the test seems to be a reasonable one because of the low morbidity and possible substantial advantage gained by knowledge of the location of the tumor.

X-ray studies in this case accurately suggested the possible location of the lesion as being in the mid portion of the gland. Fortunately it was on the surface and visible, but knowing in which area to concentrate was helpful. The histology of the specimen showed nests of islet cells without marked vascularity (Figure 2). A more positive tumor stain in this case would not have been possible.

Summary

The advantage of preoperative pancreatic arteriography in localization of an insulin-secreting tumor is demonstrated in this case report.

Episodes of tremulousness, disorientation and a low blood sugar at the time of maximum symptoms should lend suspicion to the diagnosis of insulinoma.

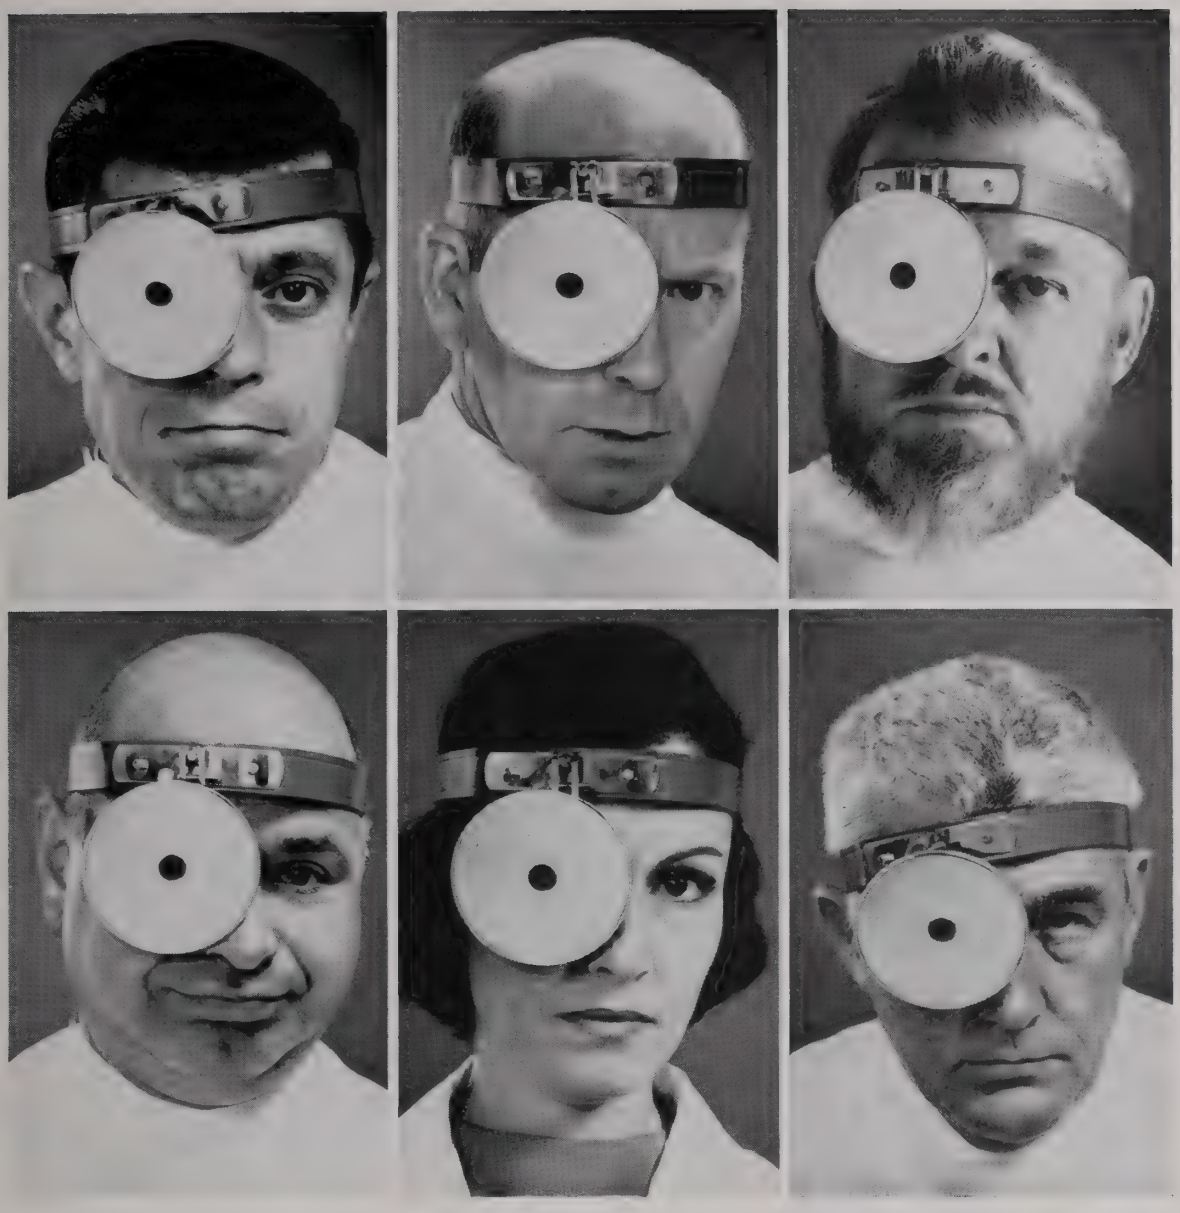
Saints and Medicine

Familiar as an April saint is Bernadette (1844-1879), identified with the shrine at Lourdes, France, the healing powers of whose grotto waters were revealed to her as a young girl by the Virgin Mary. This shrine became world-famous and continues to this day to be a Mecca for the ailing who believe in the curative properties of its waters and are sometimes mysteriously and inexplicably benefited thereby.



St. Bernadette's commemorative day is April 16.

A man loses his illusions first, his teeth second, and his follies last.—Helen Rowland

For Wallowing In

Make it a rule of life never to regret and never to look back. Regret is an appalling waste of energy; you can't build on it; it's only good for wallowing in.—Katherine Mansfield

"All Otolaryngologists are Alike"

Just look at them and you can see how much they have in common. Besides, they all go through pretty much the same training, and pass the same kinds of tests, and measure up to the same sort of standards. Therefore, all otolaryngologists are alike. Right?

Wrong! But that's no more preposterous than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more exacting. In fact, there are at least nine *specific differences* involving moisture content, purity, potency and speed of tablet disintegration, which make the manufacture of Bayer® Aspirin so different.

These Bayer standards result in significant product benefits, including gentleness to the stomach and product stability, that enable Bayer Aspirin tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that *all* aspirin tablets are alike, you can say, with confidence, that "it just isn't so."

You might also say that all otolaryngologists aren't alike, either.

Grounds...for Regroton®

chlorthalidone 50 mg.
reserpine 0.25 mg.

when you want to provide the combined benefits of two accepted agents in the treatment of mild to moderate hypertension. (Contraindications: history of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.)

when you want to prescribe therapy that is generally well tolerated.

(However, adverse reactions may occur. For a complete listing, please refer to the full prescribing information which is summarized below.)

when your patient wants an easy-to-remember and reasonably priced regimen. (One tablet a day usually costs about a dime.)

Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue 1 week before electroshock therapy, and if depression or peptic ulcer occurs. **Use in pregnancy:** Regroton should be used in pregnant patients or in women of childbearing potential only when, in the judgment of a physician, its use is deemed essential to the welfare of the patients; adverse reactions (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn. **Precautions:** Antihypertensive therapy with Regroton should always be initiated cautiously in post-sympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue Regroton therapy two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, Regroton should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000. **For details, see complete Prescribing Information.** (B)46-600-B

Argyria

In a recent article, contact sensitivity to nickel was discussed. Another interesting clinical problem with respect to metals is their deposition within the skin. This may produce either generalized or local discolorations. Metals may reach the skin either by local absorption or by way of the blood stream. As a rule, the latter route results in the general color changes associated with such metals as silver.

Argyria—This condition which results from either ingestion or the local application of silver salts and colloidal silver is characterized by a slate-blue cutaneous pigmentation. Silver nitrate, argyrol, protargol and silver arsphenamine have all been responsible, although the former use of silver nitrate internally probably accounted for the greatest number of cases. Today one may occasionally see new cases in chemical workers and workers in related occupations where silver nitrate is employed.

Argyria may be either localized or generalized. If topical application of silver nitrate has been used for a prolonged period (such as on an ulcer), the

Figure

local form of this condition may result. When argyrol was more frequently used as eyedrops, at times a diffuse periocular pigmentation resulted from absorption and diffusion of the drug. However, when silver in its several forms has been applied to mucous membranes where absorption is good or administered internally, the generalized type of pigmentation can ensue. At first the discoloration is barely perceptible and only gradually deepens, with the most pronounced changes occurring on the light-exposed areas, such as the face, conjunctiva, hands, and under the fingernails. Although the condition is clinically evident on the skin, involvement of the internal organs also occurs.

Argyria can be diagnosed very easily from a skin biopsy. Under darkfield illumination granules of silver may be seen in the lamina propria of the sweat glands (Figure), in the connective tissue sheaths of hair follicles and sebaceous glands, in the walls of blood vessels and in nerve bundles. In addition, the silver granules may be scattered diffusely throughout the dermis. Although darkfield illumination nicely demonstrates the silver, hematoxylin and eosin-stained sections also reveal granules of silver on close inspection. Of interest in this condition is the fact that the clinical coloration is not due to silver but rather to increased deposition of melanin. It appears that silver along with certain other metals has the property of stimulating melanocytic activity. Although silver is found in equal amounts in both exposed and non-exposed areas, melanin is increased far more in the light-exposed areas. For this reason the bluish pigmentation is greatest on these areas. This melanin is found both in the epidermis and below in the dermis. It is this melanin in the deeper layers of the dermis which gives the patient the slate-blue coloration. The reason for this phenomenon is stated to be that of light scattering (Tyndall effect), with blue light scattered to a greater extent than red light when passing through a turbid medium. Therefore, when pigment such as melanin lies in the dermis rather than the basal layer of the epidermis, it appears bluish.

Other—Several other heavy metals may cause slate-colored pigmentation. Gold, when given parenterally, may lead to this development, which is also most marked on areas exposed to ultraviolet light. This condition is referred to as *chrysiasis*. Bismuth, when given internally, may be associated with diffuse pigmentation or a localized variant (bismuth line on the gums). Both bismuth and mercury have in the past been used in certain cosmetic preparations (freckle creams) which lead to localized discolorations on the face and neck. With none of these conditions is it possible to reverse the pigmentary changes once they have occurred. However, eliminating the use of heavy metals and reduction of sun exposure may reduce the degree of pigmentation resulting from their use.

A. H. ROBINS COMPANY, RICHMOND, VIRGINIA 23220

Brief summary. Blurring of vision, dry mouth, difficult urination, and flushing or dryness of the skin may occur on higher dosage levels, rarely on usual dosage. Administer with caution to patients with incipient glaucoma or urinary bladder neck obstruction. Contraindicated in acute glaucoma, advanced renal or hepatic disease or a hypersensitivity to any of the ingredients.

A·H·ROBINS

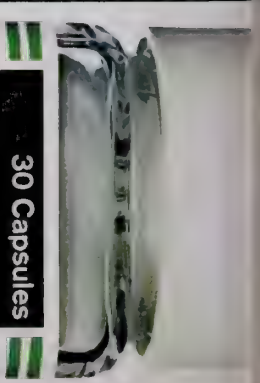
TWO WAYS TO GIVE YOUR PATIENTS A MONTH'S SUPPLY OF THERAPEUTIC VITAMIN C:

45 CABBAGES OR 30 ALLBEE WITH C

Your patient would have to eat 45 cabbages a month (1-1/2 a day) to get as much vitamin C as is contained in just one bottle of 30 Allbee with C capsules (taken one capsule daily). In addition, each capsule provides full therapeutic amounts of the B-complex vitamins. For example, as much niacin as 2 pounds of sirloin steak.

Write "30" for B and C deficiencies. This handy bottle of 30 Allbee with C capsules gives your patient a month's supply at a very reasonable cost. Also the economy size of 100. Available at pharmacies on your prescription or recommendation.

A. H. Robins Company, Richmond, Va. 23220.



A·H·ROBINS

30 Capsules
Allbee® with C

Each capsule Contains:

Thiamine mononitrate (Vit. B_1)	15 mg
Riboflavin (Vit. B_2)	10 mg
Pyridoxine hydrochloride (Vit. B_6)	5 mg
Niacinamide	50 mg
Calcium pantothenate	10 mg
Ascorbic acid (Vit. C)	300 mg

Grand Rounds

Biochemical Factors Related to the Serum Cholesterol Levels*

ARNOLD W. LINDALL, M.D., Ph.D.
Medical Resident

THE FREQUENT occurrence of elevated serum cholesterol levels in the presence of vascular disease is a generally known phenomenon. Analysis of fatty plaques in the intima of the human thoracic aorta reveals a 500% increase of cholesterol compared to normal intima; while in contrast other lipids are either normal or only slightly elevated.[1] It is not surprising, therefore, that much research effort has been devoted to the clinical and biochemical facets of cholesterol metabolism in the hope that effective means to lower serum cholesterol can be found. The control of malignant accumulations of lipid would be easier if the dynamic interrelationship between the tissue and serum pools were well understood. In reality, this can come only with basic research at the cellular level. The dangers of using poorly understood drugs to lower serum cholesterol were underscored recently with the introduction of triparonal, which had dangerous side effects related to the accumulation of a sterol intermediate, desmosterol.[2] Our purpose here will be to lay a basic foundation of knowledge about the biology of cholesterol and its relation to the clinical problem of hypercholesterolemia. The following topics will be discussed.

- Cholesterol absorption and clearance
- Plasma cholesterol configuration
- The classification of hyperlipoproteinemias
- Elements in the control of cholesterol synthesis in liver and intestine
- Evidence related to the site of action of chlorphenoxyisobutyrate
- Future research

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, November 7, 1967.

Cholesterol Absorption and Clearance

Goodman[3] recently reviewed the massive body of information on cholesterol esters. From his extensive documentation the following scheme related to dietary cholesterol absorption and disposal can be drawn. Cholesterol in the diet is absorbed in the small intestine in the presence of bile and pancreatic enzymes. Bile is necessary for solubilization, and the enzymes are necessary for cleavage of the fatty acid moiety of cholesterol esters. Only free cholesterol is transported into gut endothelium in a mechanism not related to pinocytosis. Dietary cholesterol is mixed in the intestine with cholesterol secreted in the bile. There is an enterohepatic circulation of one to three grams per day of the circulating cholesterol. In contrast to plasma, the biliary cholesterol is mainly in the free state, probably because of the presence of the surface active materials in bile. The biliary constituents themselves have interesting effects on endogenous intestinal cholesterol synthesis, as will be discussed later. Bile salt formation, of course, is one of the pathways of cholesterol metabolism.

While only free cholesterol is absorbed, it is soon esterified again and appears in the intestinal lymph in the chylomicron fraction in association with triglycerides. Evidently the intestinal microsome fraction is responsible for esterification. Peak absorption of cholesterol in man is at about nine hours post prandial.

Lymph chylomicrons are cleared by the liver parenchymal cells by pinocytosis. The heparin-activated clearing factors may be related to this process. Esterases present in both microsomal and soluble fractions are capable of freeing cholesterol from the ester form. In turn, free cholesterol can be esterified in a reaction involving microsomes, adenosine triphosphate, fatty acids, coenzyme A and cholesterol. Cholesterol oleate is the favored product. Conjugated bile salts and long-chain fatty acids inhibit this reaction in vitro.[4] The latter observations are of importance in the use of cholestyramine to lower serum cholesterol and also in the understanding of the increased free cholesterol observed in obstructive liver disease.

Dietary cholesterol is diluted with endogenously synthesized cholesterol in the liver; however, liver cholesterol ester content tends to reflect the dietary cholesterol ester pattern with regard to the fatty acid moiety. The liver, of course, is involved in plasma lipoprotein synthesis, bile salt formation and the synthesis of its own membrane systems; each of these processes consumes cholesterol and therefore affects plasma cholesterol levels.

Plasma Cholesterol Configuration

Plasma cholesterol is associated with the lipoprotein fractions and is over 80 percent esterified in contrast to tissue cholesterol which is almost all free except in the adrenal gland. It is convenient to view the lipoproteins as part of the structure of a liquid tissue, the blood, and as principally related to triglyceride transport. The presence of cholesterol may well not be related to cholesterol movement from liver to tissue; but rather cholesterol may be a structural component of the lipoproteins, just as it is in all membranes. Elevated cholesterol levels in serum should be considered in the broader context as lipoprotein abnormalities and disease classified on this basis. In order to understand current classifications of lipoproteins some understanding of methodology is necessary.

Ultra Centrifugation of Serum

Lipoproteins are separated from other serum proteins most readily by the preparative ultracentrifuge. In this instrument serum is exposed to gravitational forces of 10,000-200,000 x gravity. Such forces will ordinarily cause proteins to migrate to the bottom of a centrifuge tube. The rate of migration is a function of molecular weight, shape, and density of the protein; the other factors are the density of the media and the force applied. The quantitative description[5] known as the Svedberg equation is:

$$v = \frac{dx}{dt} = \frac{\emptyset\ (\rho_p - \rho_m)}{F} \quad w^2x$$

v = radial velocity
$\emptyset$ = particle volume
ρ_p = particle density
ρ_m = media density
F = frictional coefficient
w = rotational velocity
x = distance from rotor center

In a liquid medium particles reach a terminal velocity rapidly and then migrate at a rate directly proportional to centrifugal acceleration such that the velocity of the particle divided by the rotational force is a constant. This constant is known as the sedimentation coefficient and is a means of describing a protein in solution. The quantitative description is:

$$s = \frac{v}{w^2x} = \frac{\emptyset(\rho_p - \rho_m)}{F}$$

Usually this value is standardized to the density of water at 20°C. S $\times$ 10^{13} is equal to one Svedberg, which is the unit of description.

It can be seen that S can be postive or negative depending on the medium density. If the protein molecule is less dense than the medium, the protein molecule migrates toward the center of the rotor and S is negative. The standard condition to describe negative S is a density of 1.063. Particles which float in such a medium are classified by their flotation constant (S_F), which is the negative of the S constant. Lipoproteins which float under these conditions have S_F values from 0 to greater than 400. Various lipoproteins

TABLE 1
Clinically Important Classes of Lipoproteins Compiled from Fredrickson et al.[6]

Density of Media	G Forces	Protein Fraction Floated	S F	Class	Comments
1.006	10,000 xg 10 min.	Chylomicrons	400	very low density lipoproteins	exogenous glyceride particles
1.006	100,000 xg 24 hrs.	Pre beta lipoprotein	20-400	very low density lipoproteins	endogenous glyceride particles
1.063	100,000 xg 24 hrs.	Beta lipoprotein	0-20	low density lipoprotein	contains small amt. alpha lipoprotein known as HDL-1
1.021	100,000 xg 24 hrs.	Alpha lipoprotein	...	high density lipoprotein	subfractions called HDL-2 and HDL-3

are classified into high density, low density and very low density, based on their S_F or S values.

In practice, separate species of lipoproteins can be collected by incrementally increasing the density of serum with additions of sodium chloride and potassium bromide and carrying out successive centrifugations.[7] The first two centrifugations are done at the natural density of protein-free serum (1.006). The increments of density for the next centrifugations are 1.063 which floats the beta lipoproteins away from alpha lipoproteins* and 1.021 which floats the alpha lipoproteins from the other serum proteins. The nomenclature for the various fractions is collected in Table 1.[6]

The Soluble Lipoproteins[6]

The terms, alpha and beta lipoproteins refer to the migration of these lipoproteins on ordinary paper electrophoresis. Alpha lipoproteins migrate with alpha globulins and beta lipoproteins with beta globulins. With fat-soluble stains such as sudan black and oil red-o, the lipid component of such proteins can be easily stained. In any lipoprotein there can be up to four components.

1. A specific apoprotein.
   Proteins designated as A, B and possibly C have been recognized. The A protein is related to alpha lipoproteins while B is related to beta lipoproteins.
2. Phospholipids.
3. Cholesterol chiefly as esters.
   The smaller percentage of free cholesterol may be extremely important in exchange reactions and actual cholesterol transport.
4. Triglycerides.

Alpha lipoproteins contain 45-55% protein, 30% phospholipid, 18% cholesterol, and very little triglyceride. In contrast beta lipoproteins contain 20-25% protein, 22% phospholipid, 43% cholesterol and 10% triglyceride. In terms of content the beta lipoproteins are the major contributors to the serum cholesterol. From a study[7] which I use only as a sample, the cholesterol contents of the soluble lipoproteins are shown (Table 2).

TABLE 2
Cholesterol Content of Lipoproteins in 10 Fasted Normal Males after Havel et al.[7] units mg.% original serum ± SD

Density Class	Type	Cholesterol	Phospholipid	Cholesterol Phospholipid
1.019	Very low density + small amount of beta	26 ± 8	31 ± 9	0.84 ± 0.09
1.019-1.063	beta	97 ± 22	69 ± 13	1.41 ± 0.13
1.063	alpha	43 ± 5	111 ± 1	0.38 ± .06

In this sample 62% of the cholesterol was in the beta lipoprotein while only 28% was in the alpha fraction. The alpha cholesterol was more heavily esterified.

*A small amount of alpha lipoprotein known as HDL-1 comes with the beta fraction.

The Very Low Density Lipoproteins[8]

The fractions which carry the major load of triglyceride are the chylomicrons and so-called pre-beta lipoproteins.[1] Chylomicrons are the large particles from 0.1-5.0 microns in diameter which occur normally after a fatty meal, thus accounting for the name, exogenous glyceride particles. They consist of two components separable by starch-block electrophoresis; however, with paper electrophoresis they remain at the origin, thus being separable from pre-beta particles. Pre-beta lipoproteins occur after high carbohydrate diet or in normal fasted individuals. They are more dense and smaller than chylomicrons, and since they originate in the liver they are called endogenous glyceride, signifying the possible origin of the glyceride from hepatic synthesis. The protein content of these particles is very low, being 2.5% for chylomicrons and 2-15% for the pre-beta fraction. The lipid content for chylomicrons is 2-12% cholesterol, 3-15% phospholipid and 79-95% triglyceride. For the pre-beta class of protein, the lipid content is 10-25% cholesterol, 15-25% phospholipid and 50-80% triglyceride. The ratio of cholesterol to phospholipid and the type of protein is consistent with the presence of alpha and beta lipoprotein coated or containing triglyceride for transport.

The Classification of Hyperlipoproteinemias[9,10,11]

Five groups of abnormal lipoprotein patterns based on electrophoresis, centrifugation and genetic factors have been described.

Type I

Increased chylomicrons 14 hours after last meal. Alpha and beta lipoproteins may be decreased and free cholesterol levels may approach 50% of total. In the inherited form the heparin-activated lipoprotein lipolytic activity in serum is decreased. The best treatment appears to be dietary fat restriction; however, this may only change the serum lipids to pre-beta types. *The plasma is milky.* Other changes are increased size of the liver and spleen, lipemia retinalis and yellow skin papules. The glucose tolerance is normal.

Type II

Increased true beta lipoproteins with triglycerides not generally greater than 150 mg. %. *The plasma is clear.* A small increase in the pre-beta fraction is possible. The occurrence is frequently familial and is the most common inherited hyperlipidemic disease. The secondary pattern occurs in hypothyroidism, nephrotic syndrome and occasionally in liver disease. Tendon xanthomas are common as well as arcus senilis. Carbohydrate intolerance is not necessarily present and atherosclerosis is common. Treatment with low cholesterol-high unsaturated fat diets is successful in some cases. Drug treatment is not well established.

Type III

Increased beta lipoproteins that have a density less than 1.006 with an increase in pre-beta proteins as well. This pattern must be established with the ultracentrifuge. *The plasma is turbid* and the beta electrophoresis band is very broad. A curious diagnostic feature is lipid deposition in the palms. There is also xanthomatosis. Clinically there are increased serum cholesterol and triglycerides and often abnormal glucose tolerance. There is a familial form; the basic defect may be in the breakdown of the pre-beta proteins. Treatment includes weight reduction, unsaturated fats and low dietary cholesterol. Drugs such as Atromid may be useful.

Type IV

Increased pre-beta lipoproteins *with turbid plasma.* Triglycerides are increased and a modest cholesterol increase may occur. Alpha and beta lipoproteins are decreased. Carbohydrate diets induce this pattern in those individuals affected. Xanthomatosis, obesity, abnormal glucose tolerance and atherosclerosis are common. Familial occurrence is not well resolved. A secondary type may be present in insulin-sensitive ketotic diabetics and in pancreatitis. Insulin is less effective in the primary type IV defect. Other common diseases are glycogen storage disease, hypothyroidism, nephrotic syndrome, idiopathic hypercalcemia and alcoholism. Treatment may be by weight reduction and avoidance of high-carbohydrate diets. Atromid may be useful.

Type V

Increased chylomicrons and pre-beta lipoproteins after a normal diet with *a turbid or milky plasma.* This may not be a pure disease and a familial relationship is unclear. It may also be secondary to diabetes, alcoholism or pancreatitis. Treatment is by weight reduction. Neither dietary fats nor carbohydrates should be emphasized. Drug effects are not known.

Obstructive liver disease is considered separately by Fredrickson et al.[11] since the lipidemia is largely free cholesterol and phospholipid. High density lipoproteins are diminished.

For practical purposes the range of lipids in the various lipoproteins in fasted normals is presented in Table 3 from the data of Fredrickson et al.[9]

TABLE 3
Range of Normal Lipids by Protein Class[9]
Units: mg.%

Age Range	No. of People	Total Cholesterol	Triglyceride	Pre-beta Cholesterol	Beta Cholesterol	Alpha Cholesterol Males	Alpha Cholesterol Females
0-19	81	120-230	10-140	5-25	50-170	30-65	30-70
20-29	78	120-240	10-140	5-25	60-170	35-70	35-75
30-39	82	140-270	10-150	5-25	70-190	30-65	35-80
40-49	111	150-310	10-160	5-25	80-190	30-65	40-85
50-59	69	160-330	10-190	10-40	80-210	30-65	35-85

Elements in the Control of Cholesterol Synthesis in Liver and Intestine

Cholesterol is apparently synthesized by all tissues; however, the chief source of endogenously synthesized plasma cholesterol is probably the liver. In reality what is formed is a lipoprotein complex; but the mechanism of this formation is unknown. There is also a contribution to plasma cholesterol from the intestine.

Liver

Only a very general scheme of the biochemical steps of cholesterol synthesis will be reviewed. The history and elucidation of these reactions was reviewed by Block[12] in his Nobel prize address. Acetate is a sufficient starting material for the sequence shown in the Figure. With the background of our Figure we are prepared to examine some of the clinically important aspects of the control of cholesterol synthesis. It is now known that in mammals dietary cholesterol

will inhibit liver cholesterol synthesis both in intact animals and in liver slices. In their studies Siperstein and Fagan[13] showed the site of feed-back inhibition to be between beta-hydroxy, beta-methyl glutarate and mevalonate. The authors also demonstrated that a cell-free cholesterol synthetic system consisting of liver microsomes and the soluble fraction of liver plus appropriate media would also show such inhibition. When the dietary cholesterol was 5%, the incorporation of carbon 14 labeled acetate into cholesterol was reduced to 1% and 3% of the control in cell-free and liver-slice systems respectively. In contrast, the incorporation of labeled acetate into beta-hydroxy, beta-methyl glutarate was unaffected by dietary cholesterol, while in other studies mevalonate synthesis was inhibited about 97%. Pyridine nucleotide cofactors were not the limiting agent in this inhibition. The active cellular element carrying the enzyme sensitive to dietary cholesterol is evidently the membranous part of the microsome fraction as judged by removal of ribosomes from microsomal membranes with ethylenediaminetetracetic acid. The enzyme involved is beta-hydroxy, beta-methyl glutaryl reductase.

Cholesterol synthesis in hepatic tumors does not respond to such dietary feedback control,[14] nor does the intestine.[15] Fasting decreases both liver cholesterol synthesis[16] and fatty acid synthesis.[17]

Cholesterol

*In Siperstein's and Fagan's 13 system, the free compound and its COA derivative could not be incorporated into cholesterol; therefore, the biological compound may be a protein bound intermediate.

Figure

Intestine

The intestine is capable of cholesterol synthesis; early studies suggested that up to 18% of the plasma cholesterol came from the intestine.[18] Lindsay and Wilson recently demonstrated rather conclusively that the intestine delivers endogenously synthesized cholesterol into the intestinal lymph.[19] Rats were fed a 5% cholesterol diet which inhibited liver synthesis. Acetate C-14 injected intravenously appeared in *cannula*-diverted intestinal lymph, while blood activity remained zero. This appearance could not be due to biliary cholesterol since bile diversion from the test animal with bile restoration from a second animal gave the same results. Bile was necessary, however, for the maximal appearance of radioactivity into the lymph. When the intestinal lymph was allowed to drain into the circulatory system, blood radioactivity was appropriate for the dilution effect.

The site of cholesterol synthesis in the intestine was studied *in vitro* by Dietschy and Siperstein.[15] Lower small bowel slices incorporated acetate-C-14 into digitonin-precipitated sterols at greater rates than upper small bowel slices. Similar results were seen in the colon. The most active intestinal rates were still only one-fourth of the rate observed in the liver. The layer of gut wall most active in the synthesis was the layer of crypts of Lieberkuhn. Cholesterol feeding did not inhibit the synthesis; however, it was demonstrated that bile markedly inhibited the acetate incorporation into sterol. Above the ampulla of Vater there was active synthesis, while below, synthesis was reduced. A variety of experiments with bile perfusion confirmed this result. This result has pertinent applications to the clinical state of biliary obstruction where serum cholesterol increases. Most intestinal cholesterol synthesis probably is related to the turnover of epithelial cells.

Studies on the Site of Action of Chlorphenoxyisobutyrate

Chlorphenoxyisobutyrate was introduced by Thorp and Waring.[20] Most studies on this drug have been clinical in nature and relatively little is known about its mechanism of action. It was originally thought to require the presence of androgen; however, this is not true.[21] Many clinical studies have demonstrated a reduction of cholesterol from 15-20% and serum triglyceride from 30-40%, disappearance of xanthomas and retinal exudates, decreased plasma fibrinogen and reduced anticoagulant requirements.[21-24]

Atromid (chlorphenoxyisobutyrate and androgen) appears to affect chiefly the S_F 20-400 class of lipoproteins.[23] In a study of 14 patients with high cholesterol levels. Atromid reduced S_F 20-400 lipoproteins by 53% and S_F 0-20 by 4%. In contrast D thyroxin in the same patients decreased S_F 20-400 by 12% and S_F 0-20 by 21%. The high density lipoproteins were also affected by Atromid. Atromid increased the HDL-3 fractions by 60%. These studies suggest separate mechanisms for the two drugs and support the greater effect of Atromid on triglyceride levels.

The evidence on the cellular mechanism of action of chlorphenoxyisobutyrate is incomplete. Two studies contain data on the site of action. Azarnoff et al.[25] found that liver homogenates from cats eating a 0.2% clofibrate (ethyl chlorphenoxyisobutyrate) diet incorporated mevalonic acid-C-14 into cholesterol at only 20-40% of the rate of the control, a statistically significant decrease. In separate experiments C-14-O_2 production, lanosterol-C-14 and squalene-C-14 synthesis were all reduced by the drug, leading the authors to place the inhibition at the decarboxylation of mevalonic acid (Figure). These authors found increased liver weights. In contrast to Best and Duncan[26]

they found a decrease in total liver cholesterol as well as cholesterol concentration in spite of the increased liver weight. Equivocally decreased liver glycerides and increased liver phospholipids were observed. These changes correlate with the marked increase in liver lysosomes and mitochondria noted by Paget[27] in electron microscopic studies of chlorphenoxyisobutyrate-treated rats. Monkeys are said not to show such changes. Clofibrate may interfere with drug detoxification as indicated by the prolongation of hexobarbital sleep in rats. A most significant piece of evidence in this paper is related to the release of cholesterol and triglycerides from perfused rat livers. Triglyceride release was significantly reduced while cholesterol release was unchanged.

Another study related to mechanisms was that of Avoy et al.[28] who fed rats 0.3% chlorphenoxyisobutyrate or Atromid and found a 25% increase in liver weight, a 10% decrease in cholesterol concentration and a 30% decrease in plasma cholesterol levels. Acetate C-14 incorporation into liver-slice cholesterol was depressed 70%, while mevalonate-C-14 incorporation into cholesterol was not significantly reduced. Ketone body and triglyceride formation were not reduced, nor was intestinal cholesterol synthesis. *In-vivo* experiments were not as convincing. These results appear to conflict with Azarnoff et al.,[25] placing the block prior to mevalonic acid synthesis (see Figure). Such a site of inhibition would be similar to that of dietary cholesterol.

To summarize the meager evidence on the mechanism of chlorphenoxyisobutyrate, it appears that the drug partially blocks cholesterol synthesis prior to sequalene with no increase of toxic sterol intermediates.[22] In the plasma the decreased cholesterol is not in the principle cholesterol-bearing lipoproteins, the beta lipoprotein fraction, but rather in the pre-beta triglyceride-rich fraction. This would account for the greater efficacy of the drug in Types III and IV hyperlipidemias as suggested by Fredrickson et al.[10,11] Since the drug appears to block triglyceride release from the liver and since the liver probably makes endogenous triglyceride particles,[8] the mechanism may involve an inability to combine triglycerides with soluble beta lipoproteins or an inability to transfer such particles. The increased lysosome content may be significant in this regard. The results on triglyceride synthesis in liver are not at all convincing and further work on fatty-acid and triglyceride synthesis should be done.

Future Research

It is extremely important to establish the cellular mechanisms of drug action to ensure its use in a sensible fashion. With Atromid we know little about its effect on triglyceride synthesis. Even more poorly understood is the packaging of triglyceride with transport lipoproteins. Techniques are available and need to be used in basic cellular research on lipoprotein chemistry. In the meantime we need to establish the type of lipoprotein abnormality present in each patient before we embark on therapy. The use of Atromid or chlorphenoxyisobutyrate should be done with caution until we understand why it causes hepatic hypertrophy in rats.

Case Reports

Case 1

A 50-year-old negro female was admitted October 11, 1967, with a chief complaint of syncope secondary to antihypertensive medication. Previous problems evaluated in this hospital included: hypertension, aortic stenosis and cerebrovascular accident of undetermined age.

Renal workup negative except for narrowing of inferior branch of right renal artery noted on angiogram.

Physical Examination

Positive findings included: prominent arcus senilis, grade I arteriosclerotic changes on funduscopic examination, grade II systolic murmur and residual weakness of left arm and shoulder.

Pertinent Laboratory Findings

Cholesterol
- 5/10/67 268 mg.%
- 5/16/17 308 mg.%
- 10/11/67 415 mg.%
- 10/14/67 370 mg.%
- 10/31/67 315 mg.%
- 11/ 2/67 327 mg.%
- 11/ 3/67 330 mg.%

Phospholipids
- 10/14/67 243 mg.%

Triglycerides
- 10/14/67 74 mg.%

Protein Bound Iodine
- 5/18/67 7.6 mg.%

T_3 resin
- 5/16/67 30.2%
- 10/27/67 27.5%

I_{131} Uptake
- 10/14/67 14.5%

Glucose Tolerance Test normal.

Serum protein electrophoresis
- elevated gamma globulin fraction

Probable hyperlipoproteinemia class: Type II

Case 2

A 46-year-old white male was admitted August 3, 1967, with chief complaint of dull chest pain radiating to both arms. Past history was not informative.

Physical Examination

Positive findings included only arcus senilis.

Electrocardiogram revealed acute inferior myocardial infarct.

Laboratory Results

SGOT—Rise confirmed diagnosis of myocardial infarct.

Cholesterol
- 8/22/67 290 mg.%
- 8/26/67 340 mg.%
- 9/ 1/67 345 mg.%
- 9/25/67 390 mg.%

Protein Bound Iodine—4.6 mg.%

Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.
SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.
ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q.* 4 *h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA **SINUTAB®** FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

Book Reviews

For a good book is a solid thing.
—Pearl Buck Walsh

THE PREVENTION OF HIGHWAY INJURY—Edited by Melvin L. Selzer, M.D., Paul W. Gikas, M.D., and Donald F. Huelke, M.D. Published by Highway Safety Research Institute, The University of Michigan, Ann Arbor. 1967. Price $6.50. Copies may be obtained either from the University of Michigan Publications Distribution Service, East University Avenue, Ann Arbor, Michigan 48104, or from Clearinghouse, Code 410.14, U. S. Department of Commerce, Springfield, Virginia 22151.

Research into the causes and prevention of highway death and injury is small in amount compared to that done on cancer, cardiovascular disease and many other disorders of less consequence to the population. But an encouraging trend is developing. Among manifestations of this wholesome trend was the recent establishment in December 1965 of the Highway Safety Research Institute at the University of Michigan. One of its significant steps was to sponsor, with the University of Michigan Medical School, a Symposium on "The Prevention of Highway Injury" held April 19-21, 1967. This volume brings together the papers presented at that symposium.

The transcripts of the two opening addresses are worth the price of the book. About how many Welcoming Addresses can you say that? One was given by Robert L. Hess, Director of the Institute. No bland pabulum of welcome was this. He laid it on the line about the staggering size of the problem and the measures that will be required to come anywhere near solving it. The second talk was delivered by Dr. William G. Haddon, Director of the National Highway Safety Bureau. This was no polite high-sounding bit of fluff either; the pressing need for more and better truly scientific research in the field was highlighted. Grim fact, stern exhortation and wise philosophy pervade the entire paper.

The Symposium did not attempt to cover all the causes of collisions, but handled some of the most important, particularly those of direct or indirect medical interest. Four sections divide the material into groupings as follows: The Alcoholic Driver, Vision and Medical Impairment, Biomechanics (of injury) and The Second Collision. The papers are, without exception, by recognized authorities. There is gathered here in one volume much material which is otherwise scattered in many and varied sources, some not easily available. Much of it is fascinating, almost all is thoroughly reliable. A great deal will be new to the physician and at variance with what he sees in the popular and para-medical press, which is unfortunately his only usual source of knowledge on the subject of traffic safety. Here is the authentic source-material, not the filtered, "interpreted", and too often inaccurate rewrites.

In addition to having a particular interest in traffic safety, I happened to attend this Symposium and I unhesitatingly recommend this book. It will help the doctor-reader to an intelligent understanding of some of the major causes of death and injury related to the ubiquitous automobile. And it will give him much that will be useful in advising patients about medical factors that affect the driving task.

CARDIOVASCULAR PHYSIOLOGY—By Robert M. Berne, M.D. and Matthew N. Levy, M.D. Published by C. V. Mosby Company, St. Louis, 1967. Price: $10.75.

The preface to this book contains the usual statement that it is designed primarily for the medical and graduate student. It is one of a series on human physiology and does not cover certain areas of cardiovascular physiology, such as hematology, blood coagulation, renal, hepatic or pulmonary circulation.

Although the 242 well-illustrated pages contain a wealth of information, the undergraduate student may be well advised to retain his allegiance to one of the established textbooks of physiology. The serious graduate student, too, will find this book deficient in many aspects. Some of the presentations are by necessity, or by the author's preference, quite inadequate. The role of calcium in muscle contraction is mentioned in one sentence only. I failed to find any mention of serotonin. In the discussion of the conduction system of the heart one misses the Stannius' ligatures or reference to O. Loewi's elegant classical experiments which established acetylcholine as the depressor substance.

The emphasis in this short book is on function and regulation. The descriptions and concepts are clearly defined and always to the point. The reader is referred mainly to review articles which were selected for the comprehensiveness of their bibliographies.

However, in a book of this type, one would like to find a short but up-to-date chapter on methods of hemodynamic measurements, especially blood flow, tissue perfusion and pressures.

In short, the book lacks breadth for the beginner—and depth for the graduate student of cardiovascular physiology.

H. Wilhelm Heupel, M.D., Ph.D.
Minneapolis, Minnesota

He isn't burdened by his hypertension or his therapy...

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either the disease...or treatment

BUTISERPAZIDE provides not only the classic thiazide/reserpine formula; it supplements it with the mildly sedative effect of BUTISOL (butabarbital).

Clinical comparisons have shown that many patients respond to this treatment with (1) smooth, uniform lowering of blood pressure[1]... at times *below* the levels attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And BUTISERPAZIDE offers an added advantage: the usual dosage is just 1 tablet once or twice daily. It is available in two strengths for dosage flexibility. Are there any hypertensives in *your* practice who might find life a little pleasanter on BUTISERPAZIDE?

Contraindications: Sensitivity to any component, porphyria, peptic ulcer, ulcerative colitis, mental depression, renal impairment or shutdown. **Warnings:** Consider the possibility of sensitivity reactions in patients with history of allergy or bronchial asthma. Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions, which have led to obstruction, hemorrhage and perforation. Surgery has frequently been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occur. *Use in Pregnancy:* Exercise caution, since thiazides cross the placental barrier and may cause fetal or neonatal hyperbilirubinemia, thrombocytopenia or altered carbohydrate metabolism; adverse reactions seen in the adult may occur in the newborn. **Precautions:** ***Butisol*** (butabarbital)—Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression. ***Hydrochlorothiazide***—May induce electrolyte imbalance; when used with digitalis or one of its glycosides and in patients with severe hepatic insufficiency, cardiac arrhythmias or symptoms of impending hepatic coma may occur. Discontinue and institute appropriate countermeasures if prolonged use produces hypokalemia or (likely only with sodium restriction) hyponatremia and hypochloremic alkalosis. (Ammonium chloride, used to reverse hypochloremic alkalosis, is contraindicated in hepatic disease.) May produce elevated serum uric acid levels (and, infrequently, gout) or reduce glucose tolerance, altering insulin requirements in diabetics. ***Reserpine***—Observe for signs or symptoms of peptic ulcer or ulcerative colitis. Discontinue at first sign of mental depression; keep in mind possibility of suicide. Exercise extreme caution in history of mental depression. May produce cardiac arrhythmias when used with digitalis and quinidine, or may precipitate biliary colic in patients with gallstones. Discontinue 1 to 2 weeks before surgery; inform the anesthetist in event of emergency surgery. Exercise caution in history of epilepsy. Discontinue 1 to 2 weeks before ECT. ***General***—Reduce concomitant antihypertensives by at least 50%, and exercise caution in coronary artery disease. **Adverse Reactions:** Dizziness, drowsiness, weakness, nasal congestion, leg cramps, nausea, palpitation, superficial skin bruises, headache, dehydration, skin rash, "hangover," systemic disturbances, diarrhea, itching, vomiting, paresthesia, photosensitivity, pancreatitis, jaundice, xanthopsia, purpura, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, anorexia, gastric irritation, abdominal cramping, constipation, glycosuria, vertigo, cutaneous vasculitis, orthostatic hypotension (potentiated by alcohol, barbiturates, or narcotics), increased salivation and gastric secretion, increased intestinal motility, loose stools, angina-like syndrome, arrhythmias, bradycardia, flushing, hypotension, nervousness, paradoxical anxiety, rarely atypical Parkinsonian syndrome, central nervous system sensitization (manifested by dull sensorium, deafness, glaucoma, uveitis, optic atrophy), dryness of mouth, syncope, epistaxis, weight gain, and impotence or decreased libido. **Usual Adult Dosage:** BUTISERPAZIDE®-25 or BUTISERPAZIDE®-50: 1 tablet daily or b.i.d. *Before prescribing or administering, see package insert.*

McNEIL

McNEIL LABORATORIES, INC.
FORT WASHINGTON, PA.

Weighing on his mind, too

TABLETS

Equagesic®

(meprobamate and ethoheptazine citrate with aspirin) Wyeth®

Contraindications: History of sensitivity or severe intolerance to aspirin or meprobamate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore, it should be used in pregnant patients or women of childbearing age only when the physician judges its use essential to the patient's welfare.

Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate may result in dependence or habituation in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics. Withdraw gradually after prolonged high dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, caution patients against operating machinery or driving. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with immediate gastric lavage and appropriate supportive therapy (CNS stimulants and pressor amines as indicated).

Side Effects: Ethoheptazine and aspirin may occasionally cause nausea, vomiting, epigastric distress, and rarely dizziness. Overdosage may result in CNS depression (drowsiness and lightheadedness) or CNS stimulation and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]). Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically such as with epinephrine, antihistamine and possibly hydrocortisone. A few cases of leucopenia, usually transient, have been reported following continuous use. Rarely, cases of aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported; almost always, in the presence of known toxic agents.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Wyeth Laboratories **Philadelphia, Pa.**

When pain evokes anxiety and tension, thereby heightening patient discomfort, a simple analgesic may only touch on part of the problem.

This single-prescription, non-narcotic product, however, usually provides effective analgesia *and* helps put the patient's mind at ease.

The Cocovores

The most resolute pioneer of a natural way of life was August Engelhart. He held the remarkable view that the coconut was the only natural food for a man, since he was descended from the apes. In future he would eat nothing but this: in the morning the coconut milk, at midday the fresh pulp and at supper the dried pulp. The community that rallied to his new cure ate entirely according to the prescriptions of the master. Every other type of food was forbidden to the "Cocovores," as they called themselves. To make this natural life more realistic Engelhart demanded that his followers should go naked. This demand was difficult to comply with in Germany, on account of the police regulations and the excessive winter cold. The little band then decided to emigrate to the tropics, the original home of the human race. Money was collected; a small South Seas atoll with coconut palms and the beautiful name of Kakabon was purchased.

A chosen number of Cocovores retired here and formed the "Noble Kakabon Community," with the aim of ennobling themselves on the island through nakedness and an unremitting diet of coconuts. However, Engelhart turned out to be a tyrant who enforced Draconian laws. It was forbidden to wear any article of clothing; and although the island was full of magnificent fruit trees and bushes, only coconuts were to be eaten. The plentiful fish and shellfish to be found in every bay of the island were taboo. A prison and torture chambers were erected to punish those who infringed the law. This severity was justified by the high ideals aimed at by the coconut-nobility. Unfortunately this ideal human type was never allowed to see the light of the world: the Cocovores all died from undernourishment and severe punishment in the midst of plenty. When the British occupied the island during the first world war they found a single survivor, the coconut prophet himself. He still observed the severe ritual of his coconut diet, although his legs were swollen from starvation, and his body was covered with ulcers. As a German he was taken to a prison camp where he soon died.*

*H. S. Glasscheib: The March of Medicine, 1964.

Shakespeare and Medicine

Shakespeare knew a lot of medicine and he portrays seven doctors in his plays. Dr. Caius, of course, in the Merry Wives of Windsor is a figure of fun who threatens to perform a feminizing operation on Sir Hugh Evans if he dares interfere again with his love affairs. The English doctor in Macbeth refers to the curing of scrofula by the royal touch. Samuel Johnson was thus "touched" by Queen Anne, but with little effect. The Englishman had a wise Scottish colleague. He took one look at Lady Macbeth and said, "This disease is beyond my practice." Dr. Butts in Henry VIII, the physician in King Lear, Cornelius in Cymbeline, and Cerimon in Pericles are all good character parts and good doctors. Through them Shakespeare shows an astonishing familiarity with medical and anatomical terms and with the history of medicine. He mentions in different plays a whole heap of drugs, herbs, narcotics, and aphrodisiacs. He gave vivid pictures of the ravages of a score of different diseases and he indicated the treatment then fashionable for most of them.*

Abstracts, Briefs and Commentaries

DISAPPEARING FOOT PULSES

"In the majority of cases the organic basis (of disappearing foot pulses) is complete occlusion of the major arteries to the lower extremity." "It is not unusual, however, for pronounced clinical symptoms to be due to stenosis within these arteries." "In such cases there are often multiple stenoses of atheromatoses origin." Atheromatous plaques may be found at the bifurcation of major arteries.

Patients with isolated stenosis in a major artery of the lower extremity may have palpable pulses at rest which disappear during exercise. "A special type of arterial stenosis with this clinical symptom is the isolated stenosis at the bifurcation of the common femoral artery." Operative treatment was recommended by De Weese et al.[1] in such cases.

Case Report

Case 1.

A 40-year-old engineer had had diabetes for eight years, and for six months he had had symptoms of intermittent claudication when walking a short distance. Blood pressure was normal. Pulsations were present on both legs over the dorsalis pedis and the posterior tibial arteries at rest. On the right side these pulsations disappeared after exercise but returned in a few minutes. Arteriography was normal in both extremities except for a distinct stenosis at the bifurcation of the right superficial and deep femoral arteries.

At operation an arteriotomy was done over the stenosed area extending down the deep artery. A large obstructing atheromatous plaque causing marked stenosis was excised, and the bifurcation was enlarged by a vein patch graft. Three months later the patient had no claudication and the pulses were strong after exercise.

Case 2.

A 54-year-old woman with intermittent claudication had good pulses at rest; but they disappeared after exercise. Arteriogram showed moderate stenosis at the beginning of the deep femoral artery on the left side.

An operation similar to that in Case I was performed. A large stenosing plaque was found on the dorsal aspect of the bifurcation. Two months after surgery there was marked improvement of symptoms and the pulses were present after exercise.

Discussion

There are numerous reports of patients with arterial stenosis who have palpable pulses. Thomas (1922) first described the disappearance of the pedal pulses during exercise. Some authors attribute the disappearance to

arterial spasm. It is generally thought that the decrease in pulsation is due to redistribution of blood flow to the working muscles with relative decrease of distal pulsive flow. It has also been suggested that the disappearance is an exaggerated normal response.

It is thought that a severe stenosis is necessary to produce a distal fall of blood pressure at rest. A plaque at a bifurcation may be adequate. Surgical procedures may vary; there may be reconstruction, endarterectomy, and/or by-pass.

Stenosis of the femoral artery should be suspected in a patient with claudication despite the presence of distal pulses at rest. Disappearance of pulsations during exercise confirms the diagnosis. Arteriography should give the final proof, but the degree of stenosis cannot always be determined by a frontal projection.

PITFALLS IN THE CLINICAL USE OF CENTRAL VENOUS PRESSURE

Twenty patients had hourly examinations for urine output, hematocrit, heart rate, arterial blood pressure, skin perfusion, central venous pressure, and blood volumes.

Although the series is biased, there were nine of 20 patients in whom the central venous pressure was misleading as an evaluation of the hemodynamic state. Blood volumes were helpful, but when used alone were misleading in four of 20 patients. Central venous pressure may also be misleading because of the following factors: (a) the unique relationship between left ventricular end-diastolic pressure and left ventricular function, (b) the fact that central venous pressure is a better indicator of right ventricular than left ventricular function, (c) hypovolemia, per se, which may result in decreased left ventricular function, (d) mechanical dysfunction of catheter for various reasons, and (e) other etiologic disease of chest or heart affecting venous pressure.

Conclusion—Blood volume and central-venous-pressure determinations are most helpful when used concomitantly.

FINGER INJURY CAUSED BY PAINT SPRAY GUN

Modern grease guns which inject lubricant or paint through a small jet are capable of puncturing the skin and spreading subcutaneously some distance from the point of entry. Grease is toxic and produces a severe local reaction; even great swelling, pain and fever.

A male, 22, while adjusting a paint spray gun got his finger over the nozzle and received an injection of a small amount of paint. One hour later the finger disclosed a puncture 1/3 millimeter in diameter. There was no pain or inflammatory reaction. In view of the previous reports of similar accidents

with grease, operative exploration was performed. White paint was present in the surrounding tissues. All tissue that seemed likely to undergo necrosis was excised. The wound was left open.

The following day the entire finger was swollen and inflamed; the patient was febrile and complained of intense pain. On further exploration the paint was found to have spread more widely than found during the less radical surgery. The wound was closed loosely to permit drainage. Some necrotic tissue sloughed off. Healing required three weeks. One year later there was some atrophy and some impairment of sensation but no loss of movement of the joints of the finger.

In this instance the injected paint contained toxic ingredients, whiting and five other substances that could have toxic effects.

Comment: In some cases where grease was injected with insignificant trauma, extensive toxic inflammatory reaction and necrosis followed. Radford (Surgical Clinics of North America 43, 1277) reported 23 cases in which grease was injected and caused severe toxic inflammatory reactions.

The very high pressure causes the injected material to follow the fascial planes well beyond the point of entrance. The author recommends that the entire course of the injected material be explored.

PATTERNS OF ARTERIOSCLEROTIC LESIONS OF THE LOWER EXTREMITY

The author analyzed the arteriograms of 321 lower extremities in 189 patients. The entire arterial tree (lower abdominal aorta, iliacs, femorals, popliteals, posterior tibials, and peroneal vessels including pedal branches) was visualized. Two types of patients were studied: diabetics with atherosclerosis and non-diabetics with atherosclerosis.

Eight major patterns were discernible, the majority of which had diffuse or extensive lesions. Pathologic data indicate that the atherosclerotic lesions are usually far more advanced than the arteriograms would suggest, especially in the diabetic patient. Of the various patterns, more than 50% of the femoral-popliteal lesions were associated with aorto-iliac disease.

Comment: Very nice angiograms are presented. The need for complete aorto-iliac definition is well documented. The author employed "general anesthesia," but this has not been necessary in the reviewer's experience of retrograde "flushing" to visualize the aorto-iliac tree.

Haimovici, H.: Patterns of Arteriosclerotic Lesions of the Lower Extremity. Arch Surg 95:918, 1967.

FACTORS INFLUENCING LIMB SURVIVAL AFTER FEMOROPOPLITEAL RECONSTRUCTION

The results of reconstructive arterial surgery deserve further emphasis. These authors dealt with the following prognostic factors: (1) indication for reconstruction expressed as degree of ischemia, (2) effect of failed reconstruction on the level of amputation, (3) diabetes mellitus, (4) age, and (5) presence of recent femoropopliteal thrombosis.

Ninety-two patients (96 limbs) had primary femoropopliteal reconstruc-

tions (29 saphenous vein grafts, 34 thromboendarterectomies, 31 plastic grafts, and two arterial homografts). There were 10 secondary reconstructions because of primary failures (two vein grafts, two thromboendarterectomies, five plastic grafts, and one homograft).

Degrees of ischemia were divided into (1) claudication only (32 limbs); (2) rest pain, numbness, paresthesia (39 limbs); (3) skin necrosis (33 limbs).

Adverse factors on reconstruction were age, diabetes mellitus, type of reconstructive procedure, recent thrombosis, and degrees of ischemia. As expected, the limbs with claudication only fared the best. Vein graft reconstruction was more successful at five years than were the other procedures.

Although the patency rate for all reconstructive procedures progressively declined over five years, limb survival remained high considering the three classes: 87%, 69%, 54% respectively. A high operative mortality (26%) was associated with reconstructive procedures for acute thrombosis.

Comment: Although reconstructive surgery has definite advantages, this report again dramatizes the generalized arteriosclerotic problem—its progressive course, and the deleterious effect of operation in certain instances. The over-all clinical and economic factors relative to the patient must be evaluated prior to reconstruction.

Poseidonius: Raw-Food Advocate

The first to propose a systematic and deliberate preference for raw food was the well-known mathematician, astronomer, and Stoic philosopher, Poseidonius, who lived about 100 B.C. Both Pompey and Cicero were his pupils, and they acclaimed his wisdom. Poseidonius maintained that the human being could survive without cooking, if he were prepared to increase the work of his jaws and digestion. Cooking was only a substitute for chewing and a very poor substitute at that. Man, who possessed an oral cavity with a set of teeth, salivary glands and a tongue, needed neither a miller nor a cook, pots and pans, or even the worst of all evils, a wife standing by the oven; but a healthy human body which would serve as his own miller and cook and could attend to these tasks better and more efficiently.

Poseidonius practised what he preached: throughout his life he chewed roots, ears of corn, beans and peas, and attained the respectable but by no means extraordinary age of eighty-four.*

*H. S. Glasscheib, M.D.: The March of Medicine, 1964.

Man in this moment of his history has emerged in greater supremacy over the forces of nature than has ever been dreamed of before . . . There lies before him, if he wishes, a golden age of peace and progress. All is in his hand. He has only to conquer his last and worst enemy—himself.—Winston Churchill, 1950

Tobacco

Some things are much better eschewed than chewed; tobacco is one of them.—George D. Prentice

Photography

When the emotionally impaired patient pays an office call...

She asks for your help, but just can't seem to follow through on your advice.

When not at your office, she's constantly on the phone: can't sleep, headache, G.I. upset.

She often seeks a physical explanation for her distressing emotional state.

She's excessively apprehensive; demands much more of your nurse's attention.

In moderate to severe anxiety...

- Mellaril helps control the most frequent symptoms: marked tension, agitation, apprehension, restlessness, hypermotility
- Mellaril often alleviates anxiety-induced somatic complaints
- Mellaril frequently helps strengthen emotional resources
- Mellaril helps the patient maintain realistic contact with environment, closer harmony with family

Contraindications: Severely depressed or comatose states from any cause, and in association with or following MAO inhibitors; severe hypertensive or hypotensive heart disease.

Precautions: Hypersensitivity reactions (e.g., leukopenia, agranulocytosis) and convulsive seizures are infrequent. Pigmentary retinopathy has been observed where doses in excess of those recommended were used for long periods of time. May potentiate central nervous system depressants, atropine, and phosphorus insecticides. Where complete mental alertness is required, administer the drug cautiously and increase dosage gradually. In addition, orthostatic hypotension (especially in female patients) has been observed. Epinephrine should be avoided in treatment of drug-induced hypotension.

Side Effects: Pseudoparkinsonism and other extrapyramidal disorders are infrequent; drowsiness, especially in high doses early in treatment, may occur; nocturnal confusion, dryness of the mouth, nasal stuffiness, headache, peripheral edema, lactation, galactorrhea, and inhibition of ejaculation are noted on occasion; photosensitivity and other allergic skin reactions may occur but are extremely rare.

for moderate to severe anxiety

a solution to peptic ulcer distress

Effective neutralization—
with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

Concomitant relief of G.I. gas distress—
with the proven[1] defoaming action of simethicone.

Prolonged acceptance confirmed—
in 87.5% of 104 patients after a total of 20,459 documented days of therapy.[2]

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

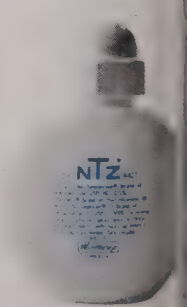
"The inconvenience of a cold"

For a cold, NTZ® Nasal Spray provides rapid relief of nasal symptoms. Relief starts with the first spray which opens the inferior part of the common meatus. A second spray, a few minutes later, will shrink the turbinates to help provide sinus drainage and ventilation. Dosage may be repeated every three or four hours as needed, for temporary relief of symptoms. NTZ is well tolerated but overdosage should be avoided.

As a sinusitis deterrent, NTZ Nasal Spray can be used to keep the nasal passages open during a cold to help prevent development of acute sinusitis—or to help prevent the acute condition from becoming chronic.



Supplied: NTZ Nasal Spray, plastic squeeze bottles of 20 ml.; NTZ Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTZ is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Special Article

Humor in Scientific Medical Writing*

RICHARD L. REECE, M.D.
Minneapolis, Minnesota

HUMOR, BY TURNING a timeworn subject upside down to glimpse the underside, may stimulate readers by giving them a new view. For example, I turn to Cecil and Loeb's *Textbook of Medicine,* where Fuller Albright is introducing "Diseases of Ductless Glands" by telling us what he, "the author," will *not* do:

". . . he will not delve into the earliest beginnings of endocrinology which had as their *raisons d'etre* such ends as the procurement of manpower safe for a harem, the salvaging of a male soprano for the choir, the increased palatability that a rooster attains when he turns into a capon, and so forth."[1]

What has Albright done? For one thing, he commands his material well enough to be unorthodox, even irrelevant. For another, he opens in such a way to lure us to the meat of the matter. By telling us what he will *not* do, Albright prods us into going on to find out what he *will* do.

Catching His Eye

The physician with too much to read often saves time by scanning introductions. Writers who want their material read appreciate this, and they set out to hook the scanner early. To catch his eye, they may use a quick opener with a surprise twist.

If you are not acquainted with this technique, I invite you to listen to this opener to "Champagne-Cork Injury to the Eye" in *The Lancet.*[2]

"Since the invention of the champagne cork towards the end of the 17th century, there appear to have been very few records of injuries to the eye from flying champagne corks. In fact we have been able to find only one article, by Tiburtius (1962), on the subject. Cooper (1859), who wrote the first authoritative textbook on eye injuries, makes no mention of such an occurrence, although he describes numerous other bizarre misfortunes. It is interesting that the inventor of the champagne cork, a Benedictine monk

*Address before the American Medical Writers' Association, September 21, 1967.

by the name of Dom Perignon, was himself blind, although the cause is not known."

Having tantalized their reader with that historical tidbit, the authors proceed to the heart of their article. Later, in their discussion, they keep his attention with this advice:

These injuries can be avoided by care in opening the bottle. The Comité Interprofessionel du Vin de Champagne has published a handbook which describes how to serve it. A napkin should be held over the cork and the neck of the bottle while the wire is being undone, and the cork is gently eased off with the bottle pointing away from the face. There should be no "pop" but merely a sigh. White gloves may be worn but are not essential.

Adapting to His Habits

Humor can serve as bait for that quick-eyed creature—the Summary Skimmer. Instead of gulping down whole journals, he skims through summaries—searching for something which suits his taste.

Had he been darting through the *New England Journal of Medicine* recently, he would have pulled up short when he read the following summary. The authors, three radiologists, are closing a report on pulmonary lycoperdonosis—a disease caused by inhaling puffball spores.

"In the interest of preventive medicine it is suggested that puffballs be gathered while young and, thinly sliced, sautéd in butter with a touch of garlic and a pinch of thyme. They are delicious prepared in this manner."[3]

Here the writers captured their readers by trolling for them. They probably knew their title—Lycoperdonosis—might snare curious, conscientious, and conventional readers, but they were after speed-reading backenders. To catch them, they dangled out the rear a morsel fit for a connoisseur.

Word Watching for Him

Then there is word watching. It is a good way of drawing fun-seeking readers into expository flow. At one time or another, most of us have poked fun at medical names or terms. It's safe, it's harmless, and it helps relieve frustrations over long, latinized words.

To illustrate word watching, I have an article from the *Journal of the American Medical Association*. Its author, Doctor Howard H. Steel, an orthopedic surgeon, is wrestling with the problem of naming toe nail and finger nail lesions which resemble Garlic-Cloves. He has already discarded the term "Steel's Nails" because it lacks modesty, and he has rejected "Hyperkeratotic Polypoid Ungual Fibroma" as stark and inhumane. Here he is leading up to his final name—"Garlic-Clove Fibroma."

"What is needed is a warm, homey sort of name. Numerous precedents exist for the use of a familiar descriptive term, a comparison with some household object . . . the silverfork deformity; the funnel breast; nutmeg liver; oat-cell carcinoma; scalloped ribs; cauliflower ear; portwine stains; doughnut pessary; sago spleen; current-jelly stool . . . coffee ground vomitus; and bringing up the rear, the grapes of wrath of the proctologist."[4]

The author's intent is clear. He wants to entertain his reader by playing on the shapes and sounds and meanings of names. Whatever his intent, I think he succeeds, for articles like his are likely to be read.

Showing Him the Gray Zones

That hazy middleground between where science stops and where art starts provides fertile soil for humor. A sense of humor, after all, is closely akin to a sense of proportion. This next specimen comes from a pathologist's pen. Doctor Sigmund Wilens is lamenting his inability to give clinicians precise scientific reasons why patients die.

"For 30 years as a practicing pathologist, I have been trying to supply the answers to that perpetual question, 'Why did he die?' It has been most fatiguing . . . until we have a bit more understanding about causes of life . . . the causes of death are apt to remain mysterious. . . . One can only speculate about the cause-of-death phraseology of the future. Will it be 'lysosomal derangement,' 'intracellular enzymatic arrest,' 'generalized impermeability of basement membranes,' 'paralysis of the reticuloendothelial system,' or 'cytoimmunological insufficiency.' "[5]

As a fellow pathologist, I find Doctor Wilens' commentary amusing. He presents a practical problem, tells of the limitations of science, and points up the incongruity of it all

by concocting a string of scientific immeasurables.

Identifying With Him

Probably the surest form of humor is to give fun to others by making fun of yourself (yourself being like other selves). All of us make mistakes, but we rarely record them in print. To publicly recount errors is novel, and therefore it has impact. Confession can make an ordinary report memorable.

Doctor Richard Asher[6] sets the stage by titling his paper "A Woman with Stiff-Man Syndrome." Having enticed us with that, he informs us that while reading about a "curious condition" he realized it was:

". . . a clear description of a case of a woman whose extraordinary spasms had puzzled me ten years previously. Luckily the ward sister remembered her name; the notes were traced and revealed the lady had continued to suffer from 'hysterical spasm'* which had disabled and deformed her. . . . I wish to report his case, (a) because I made the diagnosis ten years late; (b) because it appears to be the first case of stiff-man syndrome in England; (c) because it shows that syndromes are sometimes labelled hysterical for no better reason than they have not yet been officially described; even in this case where the patient's hysterical spasms were so titanic (and that is not a misprint for tetanic) that they bent a Smith Peterson nail and fractured a steel plate and screws."[6]

I have quoted Doctor Asher's report at some length because it shows how effective humor, especially self-depreciating humor, can be. First, Doctor Asher catches the reader's eye with his paradoxical title; then he appeals to his sympathy by confessing he diagnosed a strange disease as hysteria (haven't most of us?); and then he cleverly plays "titanic" against "tetanic" to show the magnitude of his mistake and to etch on the reader's mind a dramatic aspect of the disease.

Appealling to His Intellect

Mention of the word "titanic" brings to mind a piece by Joseph Garland, who recently retired as editor of the *New England Journal of Medicine*. In the following editorial—"Wordupmanship, No Less"[7] he shows his bent for wit, that felicitous form of humor which is part perception, part ingenuity, part joining of seemingly unrelated things. Doctor Garland is having his go at the uses and abuses of the suffix "ship," particularly whether it should be appended to the word "relation."

He closes in this fashion.

"The case in favor of relation and against relationship except in a restricted sense having thus been clearly presented and incontrovertibly proved, it may be pertinent to recall a luncheon-table conversation about the sinking of the Titanic that took place in the Harvard Club of Boston, on the anniversary of that melancholy event. 'I had relations on the Titanic,' one discussant modestly admitted. 'With whom?' was the spontaneous interrogation of his fellow Harvardmen, striving for their own scholarly version of one-upmanship."[7]

Helping Him to Grin and Bear It

Then there is satire, which is nothing more or less than a thinking man's humor. Satire has bite, but it isn't mean. It should give information and insight as well as provoke a smile as has been done by Clifton Meador,[8] a Markle Scholar in Academic Medicine, in describing "The Art and Science of Nondisease."

"In a review of the charts of patients referred to the Endocrine Division with a variety of diagnoses it became apparent that a large number also had no disease. They were not *just* healthy; they had specific nondisease . . . a nondisease exists when a specific entity is suspected but is not found."[8]

Doctor Meador is not indulging in idle gamesmanship. He is inviting readers, many of whom are undoubtedly referring physicians, to *think* the next time they diagnose an endocrine disease. For, as Doctor Meador points out: ". . . the treatment for nondisease is never the treatment for the corresponding disease entity. In this statement lies the ultimate value of the science of nondisease."

The Case for Humor

So far in this presentation, one person has been very much in the news—the reader. If a writer is going to be read (and I assume most of us want to be read), we had best keep the reader in mind. We must sympathize with

*Asher's original diagnosis.

him, anticipate his needs, inform him, and, if appropriate and in good taste, amuse him.

To me the case for humor is clear. It is personal, it is human, it is readable. If our journals are to be actively read, (there's that word again) rather than to passively gather dust as storehouses of facts, they need to be enlivened. Humor can help us pump a little humanity into the flood of medical articles that cascade off the presses.

I am not saying humor is invariably right. Doctors deal with disease, human distress, and death. These are matters not taken lightly. Also, they usually tackle scientific subjects; and science, almost anyone will grant, is a serious business. Medical scientists are expected to grind out facts. To present these in an entertaining fashion is often difficult and sometimes impossible. Medicine, then, calls for serious men saying serious things, in a responsible manner. I do hope, however, the writer will occasionally laugh at himself, amuse his readers when it helps to hold their attention, warm up his facts before he serves them, and use humor whenever it adds a touch of humanity. As as veteran practitioner of prose, Alistair Cooke of the *Guardian* of England, remarked while addressing the Annual Convocation of the Mayo Graduate School of Medicine: ". . . And let us not get too solemn about what is meant by humanity; it ought always to mean compassion; but it might also include humor, which dignifies the giver and the receiver and is an excellent medicine in itself."[9]

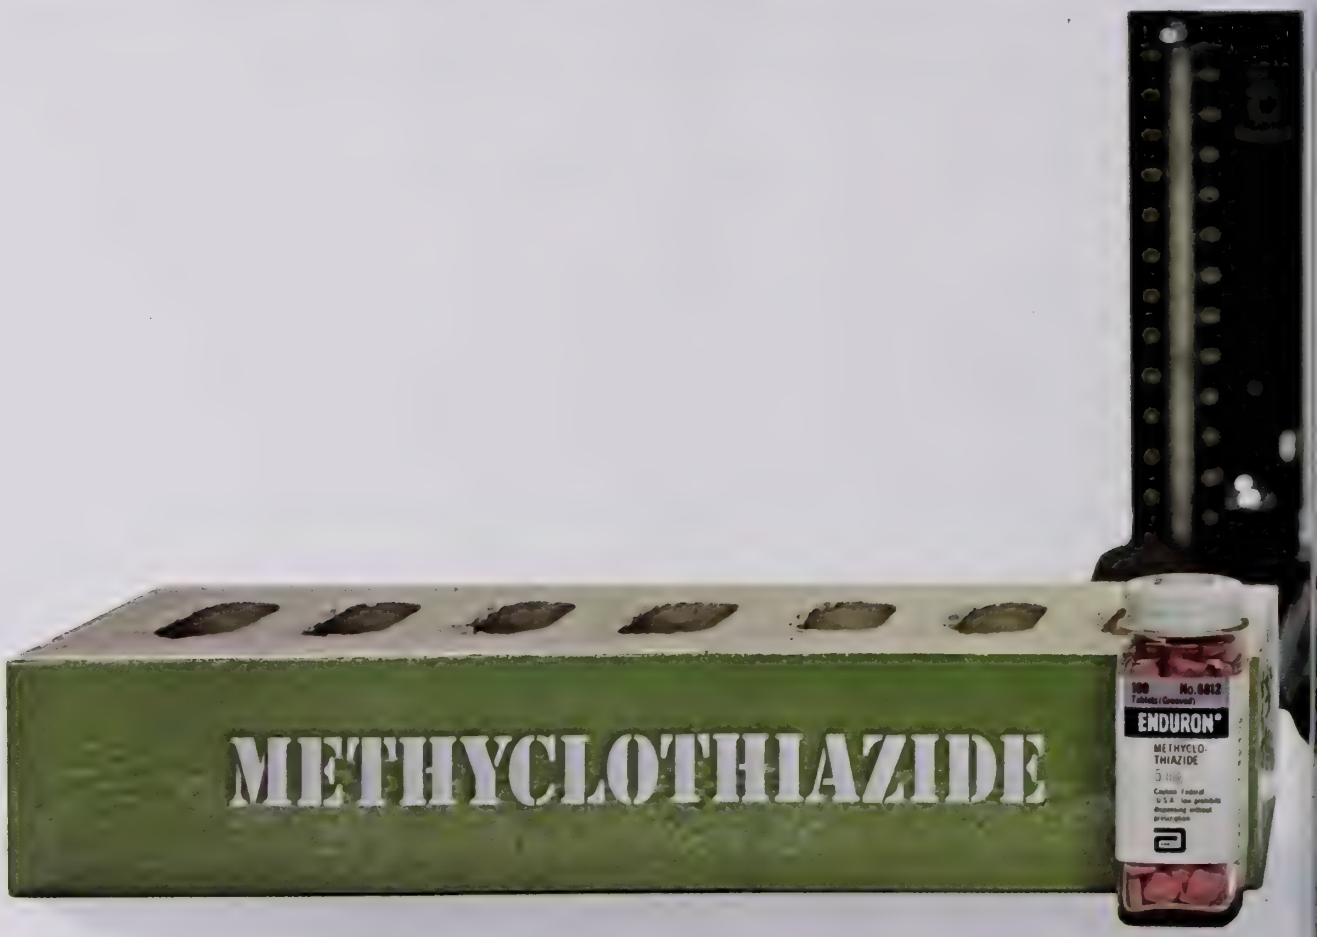
Tuberculosis Symposium

An all-day symposium on Clinical Pulmonary Problems, sponsored by the Ramsey County Tuberculosis and Health Association, will be held Friday, April 19, 1968, at the St. Paul-Ramsey Hospital.

Sessions will begin at 8:30 A.M. with registration and run through to 5:30 P.M. No registration fee is being set, but there will be a charge for luncheon and dinner.

Featured speakers will be Averill Liebow, M.D., Professor of Pathology, Yale University School of Medicine, and John Rankin, M.D., Professor of Medicine, University of Wisconsin Medical School. Other faculty members will include full-time or clinical staff members from the Mayo Medical Center and from the corps of Twin Cities physicians.



Dr. Liebow, an emminent authority on pulmonary work, will address the conference at a morning session and will be the featured dinner speaker, scheduled for 7:00 P.M. that night at the St. Paul Hotel. Reservations for dinner may be made by calling 224-4901, the TB Association office.

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

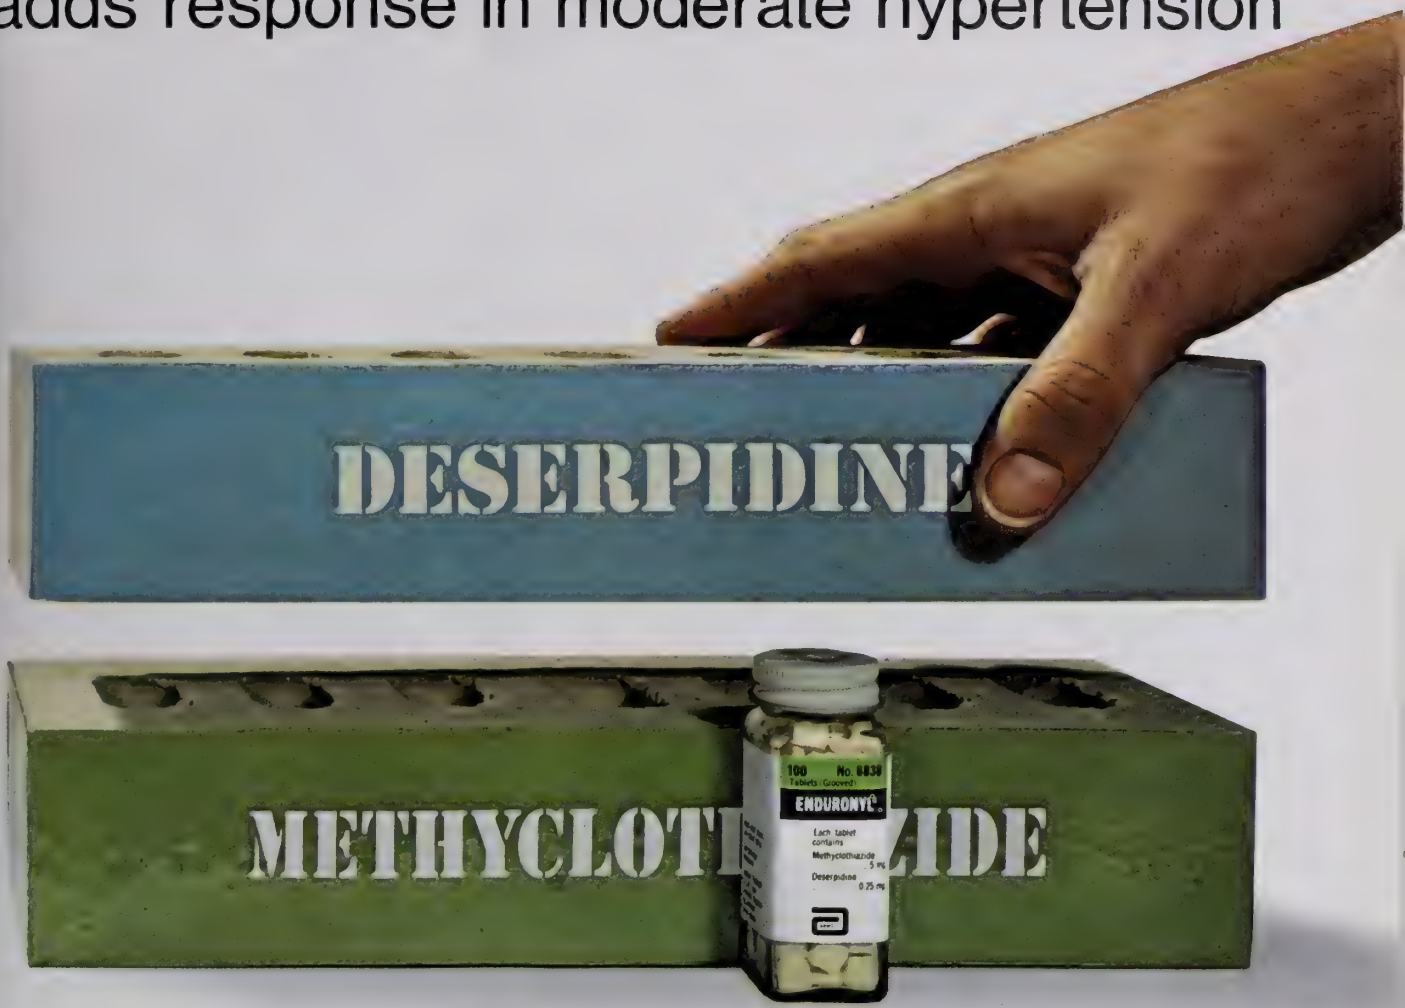
The therapeutic action is smooth, and persists for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

Of course, as with all thiazides, supplemental dietary potassium should also be considered.

Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

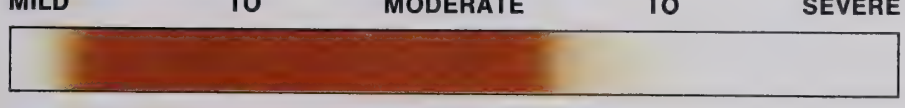
See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

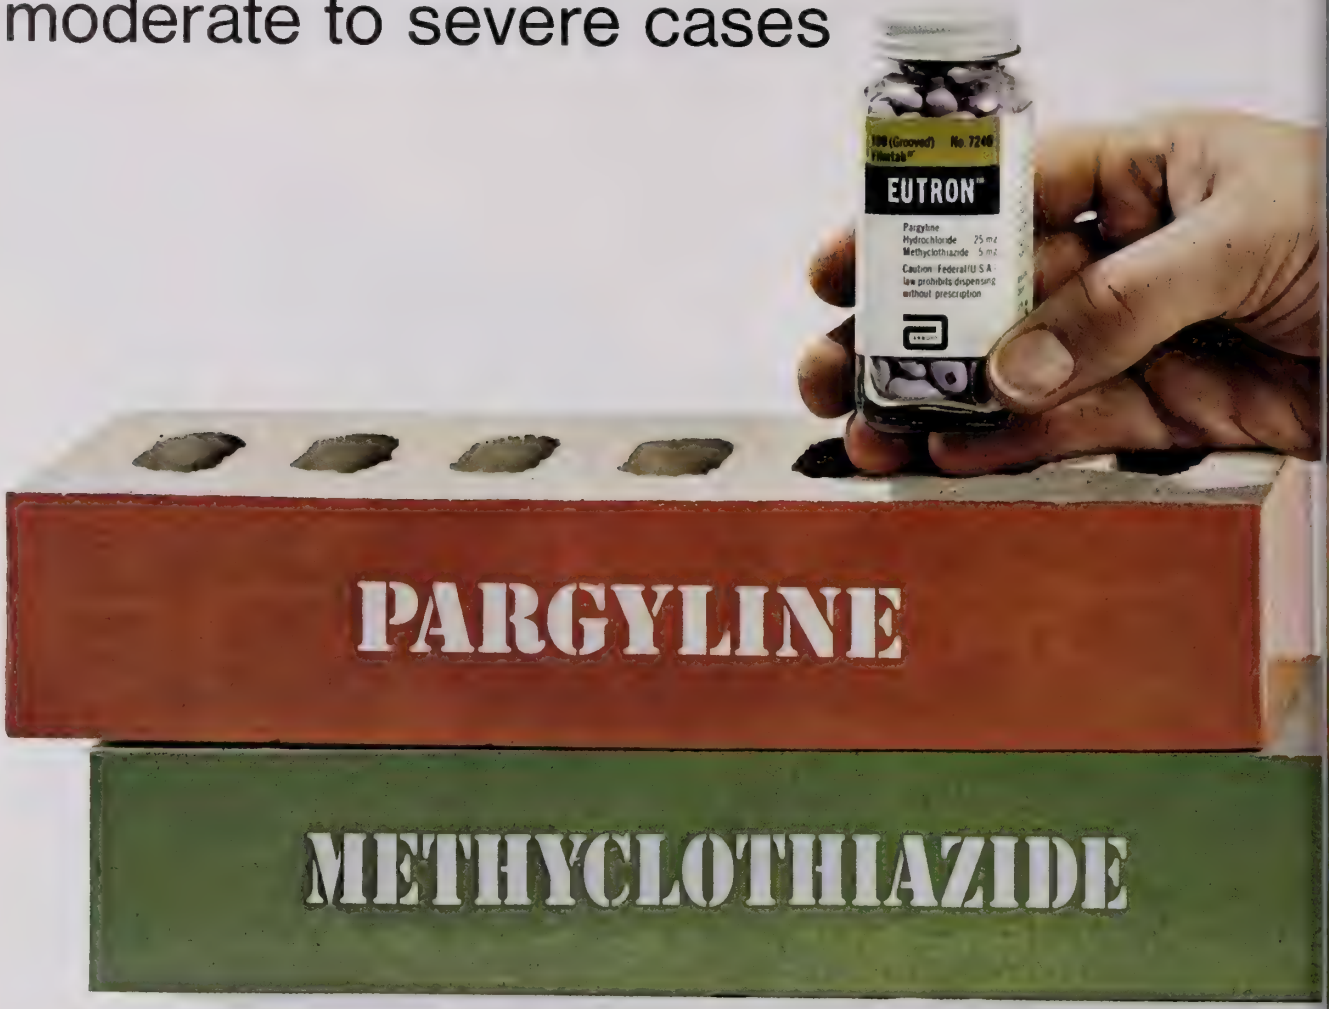
Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.



Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day



ENDURONYL®

METHYCLOTHIAZIDE 5 mg. with DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.

See Brief Summary on final page of advertisement

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg.

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications—Moderate to severe hypertension.

Contraindications—Pheochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Not recommended in malignant hypertension, children under 12, pregnant patients.

Do not use with: centrally or peripherally acting sympathomimetic drugs; foods high in tyramine (e.g., aged and natural cheeses); parenteral reserpine or guanethidine; imipramine, amitriptyline, desipramine, nortriptyline or their analogues; other monoamine oxidase inhibitors; methyldopa or dopamine; separate Eutron and these agents by two weeks.

Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease; impending hepatic coma from thiazide-induced hypokalemia.

Warnings—Patients: 1. No other drugs (particularly "cold preparations" and antihistamines), cheese or alcohol without physician's consent. 2. Promptly report orthostatic symptoms, severe headache, other unusual symptoms. 3. Angina pectoris or coronary artery disease patients must not increase physical activity with improved anginal symptoms or well-being.

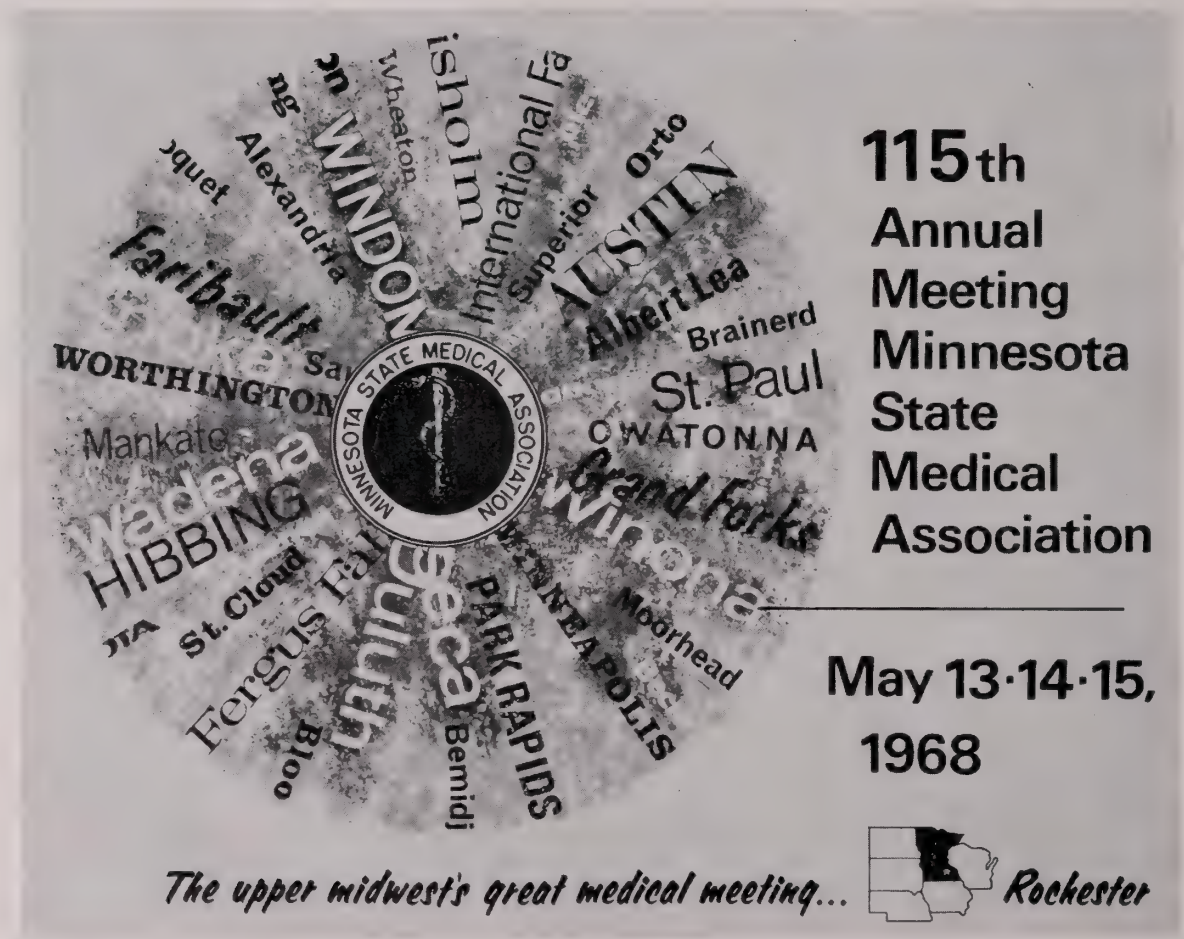
Physicians: 1. Use antihistamines, hypnotics, sedatives, tranquilizers and narcotics (meperidine contraindicated) cautiously in reduced doses. 2. Stop Eutron two or more weeks before elective surgery; in emergency surgery reduce premedication (narcotics, sedatives, analgesics, etc.) to 1/4 to 1/5; carefully adjust anesthetic dosage to patient response. 3. Use cautiously in advanced renal failure. 4. Pargyline may induce hypoglycemia. 5. Consider possible sensitivity reactions when a history of allergy or asthma is present. 6. If potassium is indicated, dietary supplement is recommended; enteric-coated potassium tablets may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation frequently requiring surgery; discontinue medication immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occurs; Eutron does not contain added potassium. 7. Possible systemic lupus erythematosus has been reported for thiazides.

Precautions—Pargyline: Use cautiously at reduced dosage: caffeine, alcohol, antihistamines, barbiturates, chloral hydrate, other hypnotics, sedatives, tranquilizers, narcotics. Periodically do urinalyses, blood counts, liver function tests, etc. Use with caution in liver disease. Watch for orthostatic hypotension, especially in impaired circulation (e.g., angina pectoris, coronary artery disease, cerebral arteriosclerosis); also, augmented hypotension in concomitant febrile illnesses. Reduce or discontinue if hypotension is severe. In impaired renal function watch for cumulative drug effects, elevated BUN and other evidence of progressive renal failure; withdraw drug if these persist. In surgery increased central depressant response (hypotension and increased sedative effect) can be controlled by (1) discontinuing at least two weeks prior; (2) in emergency surgery lowering dose of premedication; (3) when necessary, administering a vasopressor. Do not use in hyperactive and hyperexcitable patients. Pargyline may unmask severe psychotic symptoms where emotional problems pre-exist. Use cautiously in Parkinsonism, especially with antiparkinsonian agents. In prolonged therapy, examine for change in color perception, visual fields, fundi and visual acuity. Also, prolonged therapy has made certain patients refractory to nerve blocking effects of local anesthetics.

Methyclothiazide: Use cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery thiazide may reduce vasopressor response and increase tubocurarine response. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia). Give supplemental chloride if hypochloremic alkalosis occurs and supplemental potassium if hypokalemia occurs (especially in digitalized patients). Thiazides may decrease serum P.B.I. without signs of thyroid disturbance.

Adverse Reactions — Pargyline: Orthostatic hypotension and associated symptoms, mild constipation, fluid retention, edema, dry mouth, sweating, increased appetite, arthralgia, nausea, vomiting, headache, insomnia, difficult in micturition, nightmares, impotence, delayed ejaculation, rash, purpura, weight gain, hyperexcitability, increased neuromuscular activity and other extrapyramidal symptoms. Drug fever is extremely rare. Reduction in blood sugar and hypoglycemic effects are possible. Congestive heart failure has been reported in a few patients with reduced cardiac reserve.

Methyclothiazide: Blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, blood sugar or serum uric acid (gout may be induced); anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice and pancreatitis. Cutaneous vasculitis in elderly patients has been reported with other thiazides.



If side effects are severe or persist, reduce dosage or withdraw drug. 804438R

ABBOTT

TM-TRADEMARK

Annual Meeting

Rochester Will Host Our Annual Meeting

HEART, BLOOD, Bones, Shock, Sex will be the program headliners for the 115th Annual Meeting of the Minnesota State Medical Association, May 13, 14 and 15 in Rochester.

The Committee on Scientific Assembly notes that the treatment "in depth" of several major topics represents a new concept in programing, and speakers will include outstanding Minnesota physicians as well as a number of visiting dignitaries.

The scientific sessions, which will treat each of these topics from A to Z, are especially designed to be of practical interest to every physician.

Morning and afternoon sessions will be at the Mayo Civic Auditorium and will begin at 9:00 a.m. each day. It is expected that four-and-a-half hours of credit will be allowed for attendance at each full day by the American Academy of General Practice.

New concepts in the management of patients with acute myocardial infarction will be discussed at the opening session on Monday. Participants include: Doctor Edward A. Ryan, Duluth and Doctors Emilio R. Giuliani, Harold T. Mankin and Carlos E. Harrison, Jr., all of Rochester.

Doctor Norman E. Shumway, Thoracic Surgeon of Stanford University Medical School, Palo Alto, will give the principal address at the morning session. He will also act as leader at a Round Table Discussion Luncheon on Medicine and Religion.

The Monday afternoon session on blood will feature an address by Doctor Harry S. Jacob entitled "Mechanisms of Hemolysis in Hemolytic Anemia." Doctor Jacob is currently at Tufts University Medical School, Boston. Beginning July 1, 1968, he will be Hematologist and Associate Professor in the Department of Medicine at the University of Minnesota School of Medicine. Other participants are: Doctors Robert A. Green, Program Chairman on Blood, James L. McKenna, Howard L. Horns, and F. Bruce Lewis, all of Minneapolis; and Murray Silverstein and Joseph M. Kiely of Rochester. These physicians will all participate in rotating group subjects on a variety of topics concerned with disorders of the blood, with an exchange of questions and answers between them and participants in small groups.

To conclude the afternoon there will be a panel made up of these authorities to conduct a major question and answer period from the entire group in some specific areas of blood diseases.

Attendance at this session will provide physicians the opportunity to become better acquainted with new medical school faculty member Doctor Jacob.

Doctor Richard C. Lillehei, Professor of Surgery, will serve as chairman for the program of Shock on Tuesday, May 14, at 9:00 a.m. Speakers and their subject titles for the program on shock are:

Wesley J. Spink, M.D., Minneapolis—"Pathogenesis and Management of Endotoxin Shock"

William J. Martin, M.D., Rochester—"The Choice of Antibiotics in Management of Bacteremia and Shock"

Vincent J. Collins, M.D., Chicago—"The Prophylaxis of Shock"

Richard C. Lillehei, M.D., Minneapolis—"Monitoring of Patients in Shock"

Doctor Collins is Chief of the Department of Anesthesiology at Cook County Hospital, Chicago. He will also act as leader for a Round Table Discussion Luncheon on Local Anesthesia in Management of Injuries to the Extremities.

Physicians will have an opportunity to "meet the chiefs" at the 11:00 a.m. session on Tuesday morning. Recent additions to the University of Minnesota Medical School faculty and staff will be introduced by Dean Robert B. Howard. There will also be an opportunity at later Round Table Discussion Luncheons for physicians to discuss with the "chiefs" changes in medical education, including proposed changes in the medical school curriculum geared to family practice.

The following "chiefs" will be introduced at this session:—

John S. Najarian, M.D.
Professor and Head, Department of Surgery

Richard V. Ebert, M.D.
Professor and Head, Department of Medicine

John J. Sciarra, M.D.
Professor and Head, Department of Obstetrics and Gynecology

Michael Paparella, M.D.
Professor and Head, Department of Otolaryngology

John H. Westerman, Director
University Hospitals

Types of bone disease, reaction of bone to trauma, tumors, fractures, tissue response to trauma—all aimed toward the physician in family practice—will be presented at the 2:00 p.m. session on Tuesday. Doctor Harry B. Hall, Minneapolis, Chairman of this session, announces the following participants in a program series to be called "Bone Decisions by the Decade:"

Edward L. Salovich, M.D., Minneapolis
Leonard O. Langer, Jr., M.D., Minneapolis
Richard H. Jones, M.D., Minneapolis
H. Wilson Godfrey, M.D., Minneapolis
Harry B. Hall, M.D., Minneapolis
S. Hartley Calin, M.D., Minneapolis

At 4:30 three panelists will discuss "Diagnosis and Treatment of Benign and Malignant Tumors of the Blood." They are:—

John C. Ivins, M.D.—All of Rochester
David C. Dahlin, M.D.
Harry F. Bisel, M.D.

A wide variety of individual discussions under the title "Sex" will be conducted at the opening session Wednesday, May 15, at 9:00 a.m. Co-chairmen for this session are Doctors Maurice J. Martin and Richard M. Steinhilber, both of Rochester. Specific subjects will be treated on the basis of the practice-oriented setting—in terms of counseling, marital-sexual conflicts, adolescence and sex. The emphasis will be on normal, rather than abnormal, situations. The panel will keep its formal remarks to a minimum with emphasis on audience participation.

The traditionally popular round table luncheons scheduled for Monday and Tuesday noon will deal with a variety of topics of current interest to physicians. Round table topics include: medicine and religion, use of the gastric camera, family practice, philosophy of transplants, dermatology, the Keogh bill, heart, blood and anesthesiology.

The House of Delegates will convene Sunday, May 12, at 2:00 p.m. and again on Monday, May 13, at 7:30 p.m. Delegates are advised to note this change in time for the second session, traditionally held Tuesday morning.

The New Members, County Officers and Delegates Dinner is scheduled for Sunday, May 12, at 6:00 p.m. Reference committees will meet at 8:00 p.m. following the dinner. Many of the scientific and non-scientific committees of the Association have scheduled 7:30 breakfasts, during the session, and physicians are urged to consult their official program for exact time and location of specific committee meetings.

The annual Minnesota State Medical Association banquet is scheduled for 7:00 p.m., Tuesday, May 14, and will be preceded by the president's reception at 6:00 p.m.

The NUHOPE-AMPAC members will hold their annual dinner on Monday, May 13.

The Committee on Scientific Assembly is pleased to announce that this year's scientific and technical exhibits will be particularly outstanding. Physicians are urged by the committee to visit the exhibits and express their appreciation to the technical exhibitors whose annual participation at our meetings has helped to make the perennially excellent scientific sessions possible. Ample time to visit the exhibits will be provided between scientific sessions. Additional annual meeting information will appear in the next issue of MINNESOTA MEDICINE and in the monthly NEWSPAGE.

The official program and registration cards will be mailed to all physicians.

—Jacob Brande: Speaker's Encyclopedia

Progress

Democracy is ever eager for rapid progress, and the only progress which can be rapid is progress down hill.—*Sir James Jeans*

b.i.d.

The sensible schedule that covers the patient day and night

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, then you know why b.i.d. DECLOMYCIN is considered to be a sensible dosage schedule.

The maintenance dosage of DECLOMYCIN can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

The b.i.d. dosage of DECLOMYCIN gives you the comfortable assurance that the patient is well-covered, *day and night.*

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective; because of high serum binding and slow renal clearance. And if there's a broader susceptibility pattern of organisms, we've yet to see it.

There is no need to give higher daily dosage than 300 mg b.i.d., except in venereal diseases and Eaton Agent pneumonia.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Lederle

Prescribing information on next page.

b.i.d. The sensible schedule that covers the patient day and night

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

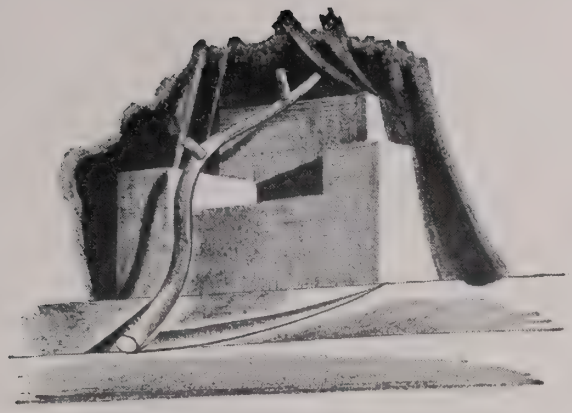
Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occure. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes. A rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth— dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm. given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.



Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg. of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg. every 6 hours for a minimum of 4 doses or 300 mg. every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg. every 6 hours or 300 mg. every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg. in 3 divided doses for six days.

In Memoriam

God's finger touched him, and he slept.—Tennyson

ARTHUR W. IDE, M.D.

Dr. Arthur W. Ide, 92, St. Paul surgeon, died February 11. Born in Creaton, Iowa, he obtained his medical education at the University of Michigan.

Dr. Ide joined the staff of the Northern Pacific Hospital at Brainerd in 1905, and later became chief surgeon and moved to St. Paul in 1921. He remained chief surgeon until he retired in 1943.

He was a member of the Ramsey County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by two sons, one of whom is Dr. Arthur W. Ide, Jr., of Minneapolis.

PETER BALEISIS, M.D.

Dr. Peter Baleisis, 51, who had practiced medicine in North Minneapolis for the past thirteen years, died suddenly January 14. He graduated from the University of Dusseldorf, Germany, in 1948 and came to this country two years later joining the staff of St. Joseph's Hospital in South Bend, Indiana. In 1954 he became associated with the Broadway-Suburban Clinic in Minneapolis.

He was a member of the American Medical Association, the Minnesota State Medical Association, the Minnesota Academy of General Practice, and the Hennepin County Medical Society.

Dr. Baleisis is survived by his wife, a son and a daughter.

LESTER R. PARSON, M.D.

Dr. Lester R. Parson, 76, Elbow Lake physician, died in his sleep January 23. Born in Jackson County, Minnesota, Dr. Parson taught in rural schools when not farming. Later he attended the University of North Dakota for his premedical training and graduated from Rush Medical College in 1921. In 1923 he moved to Elbow Lake where he and his wife, Dr. Lillian Parson, practiced medicine until January, 1960, when Dr. Lester retired.

He was a member of the American Medical Association and the Park Region District and County Medical Society and was a Life Member of the Minnesota State Medical Association.

He is survived by his wife, a son and a daughter.

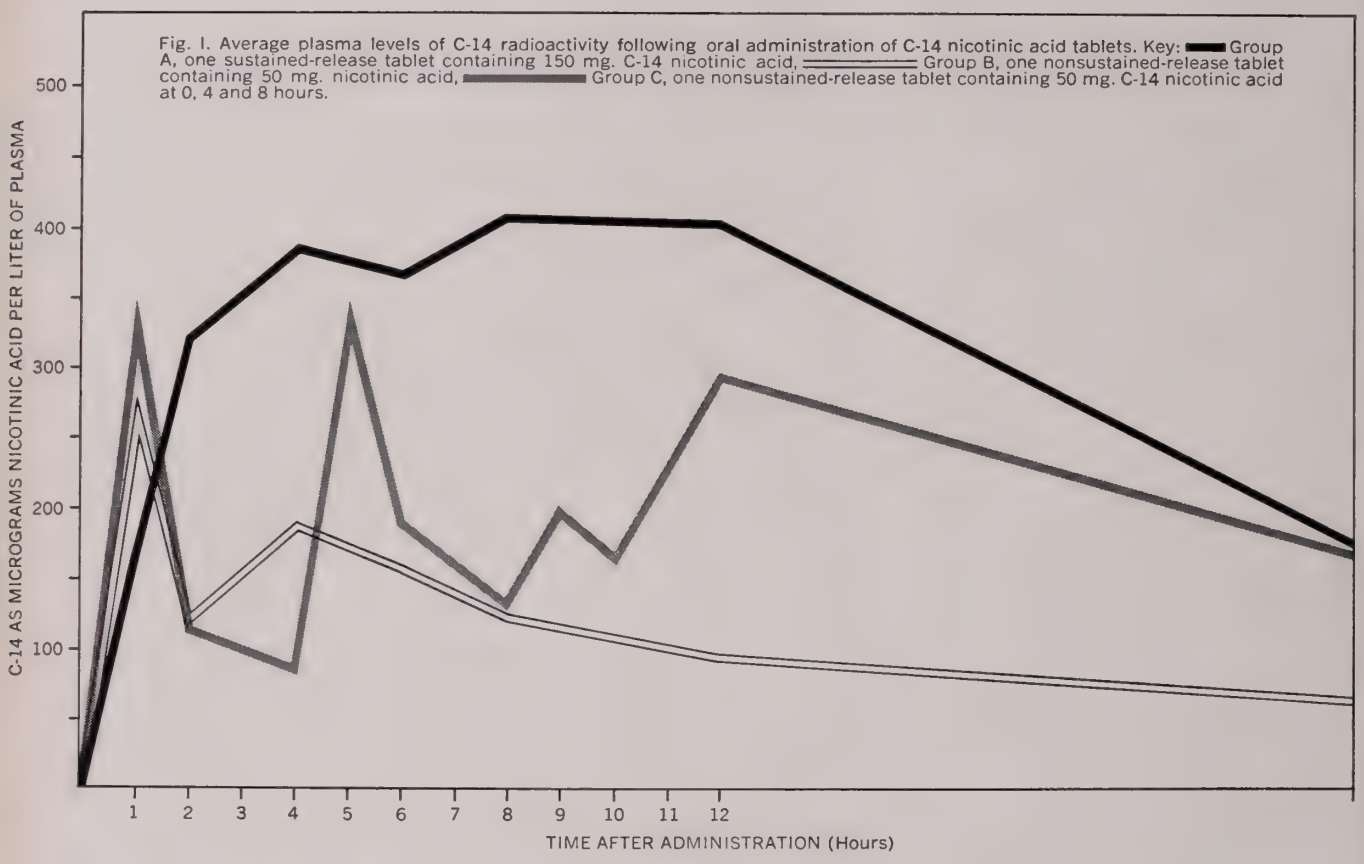
THOMAS O. YOUNG, M.D.

Dr. Thomas O. Young, 74, prominent Duluth physician, died February 2, in a Duluth hospital after a long illness. Born in LeRoy, he had been a Duluth resident for forty-three years. He graduated from the University of Minnesota Medical School.

A founder and first president of the Duluth Surgical Society, Dr. Young was on the surgical staffs of St. Mary's, St. Luke's and Miller Hospitals. He had been elected to the honorary medical staff of St. Mary's the day before his death.

He was a member of the St. Louis County Medical Society, the American Medical Association, the American College of Surgeons, the Society of Abdominal Surgery, the American Thyroid Society, the Academic Internationale of Medicine, and a Life Member of the Minnesota State Medical Association.

He is survived by his wife and three sons, two of whom are Dr. Hadley Young and Dr. Allen A. Young of Duluth.



MORRIS H. SHERMAN, M.D.

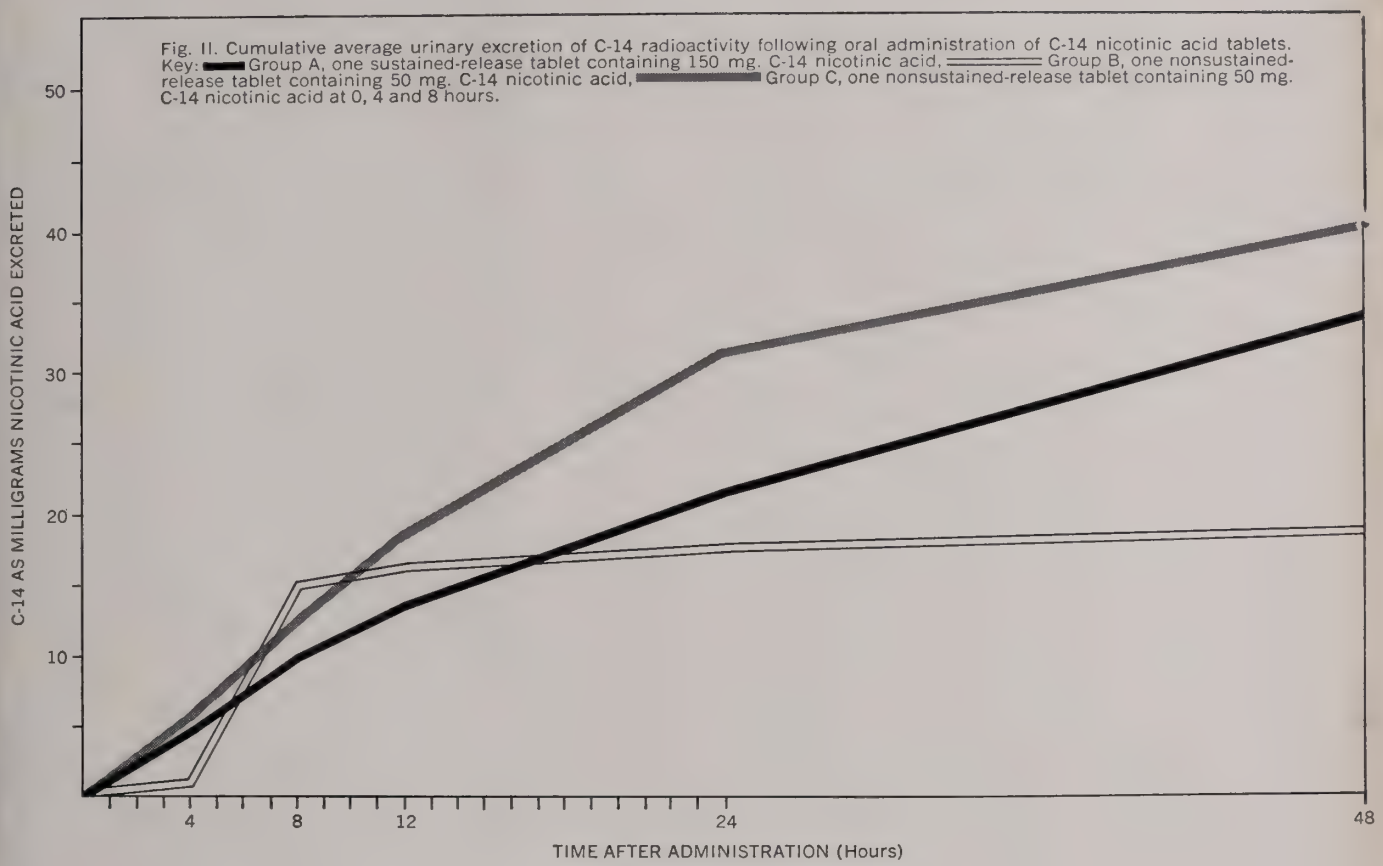
Dr. Morris H. Sherman, 44, Minneapolis internist, died February 10, of a heart attack. Born in Minneapolis, Dr. Sherman graduated from the University of Minnesota Medical School in 1946.

He was a staff member of Mount Sinai Hospital and on the Board of Directors of the Minneapolis Talmud Torah. Dr. Sherman was also a member of the American Medical Association, the Hennepin County Medical Society and the Minnesota State Medical Association.

He is survived by his wife, a daughter and two sons.

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by absent-minded patients)



Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Geroniazol® TT

nicotinic acid 150 mg., pentylenetetrazol 300 mg.
Tempotrol® Time Controlled Tablet

Tissue's healing nicely. Yet anxiety slows his steps toward recovery.

By helping overcome anxiety and tension which can thwart the convalescent's progress, Equanil® often may play an important role in medical and surgical aftercare.

Indications: For use in management of anxiety and tension occurring alone or as accompanying symptom complex to medical and surgical disorders and procedures. Though not a hypnotic, fosters normal sleep through antianxiety and related muscle-relaxant properties.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

Last month this feature defined Regional Medical Programs and described the origin of the Minnesota Program. The question and answer format will be continued to describe the program.

What is a Region?

There are 54 Regional Medical Programs in the country. They vary geographically from a small part of one state (Metropolitan New York) to parts of five states (Intermountain Region centered on Salt Lake City, Utah). Most Upper Midwest Regions follow state lines (Iowa, Wisconsin, Minnesota, North Dakota). Nebraska and South Dakota joined to form one region.

What are the Medical Centers of Regional Medical Programs?

A medical center is defined as "a medical school or other medical institution involved in post-graduate medical training and one or more hospitals affiliated therewith for teaching, research and demonstration purposes."

In Minnesota the University of Minnesota College of Medical Sciences and the Mayo Foundation are the medical centers.

Where are the Central Offices of Northlands Regional Medical Program?

Northlands Regional Medical Program offices are located in the new quarters of the Minnesota State Medical Association on the fifth floor of the new Farm Credit Banks Building at 375 Jackson Street in Saint Paul, Minnesota

How does Northlands Regional Medical Program Operate?

Authority rests with an Executive Committee consisting of one representative from each of the nine sponsoring organizations. The Program Coordinator, Chairman of the Executive Committee, and representative of the Minnesota State Medical Association, is Dr. J. Minott Stickney. Other members of the committee with the organizations they represent are: Jack Rivall, M.H.A., Minnesota Hospital Association; Robert A. Ulstrom, M.D., University of Minnesota College of Medical Sciences; Jack P. Whisnant, M.D., Mayo Foundation; Robert N. Barr, M.D., Minnesota Board of Health; William F. Mazzitello, M.D., Minnesota Heart Association; Donald E. Stewart, M.D., Minnesota Cancer Society; Paul M. Ellwood, M.D., American Rehabilitation Foundation; and Harold W. Brunn, L.L.B., Minnesota State Medical Association Foundation.

A Regional Advisory Group composed of lay and professional representatives of health related organizations is required by law to appraise and approve all operational programs.

Who are Employed by Northlands Regional Medical Program?

The following personnel are employed full-time in the Central Office: Winston R. Miller, M.D., Program Director; Robert J. Wilkins, M.H.A., Associate Director; Ivan J. Fahs, Ph.D., Medical Sociologist; and Lawrence B. Stadler, M.P.H., Coordinator for Heart Disease Programs. Unfilled positions call for a Biostatistician and Research Associates or Coordinators.

The following personnel are employed at the Medical Centers (all but one are part-time): Mayo Clinic: J. Minott Stickney, M.D. and Jack P. Whisnant, M.D.; University of Minnesota College of Medical Sciences: Robert A. Ulstrom, M.D.; W. Albert Sullivan, M.D.; and Lee D. Stauffer, M.P.H. (full-time).

The program also pays for time and expenses of laymen and physicians from throughout the state who serve on working committees.

Can Federal Subsidies Weaken the "Town-Gown" Syndrome and Other Bigoted Barriers to Facilitate More Effective Delivery of Health Care Services?

This is the crucial question. In Minnesota, as in 53 other "regions," we are given the chance to try.

Winston R. Miller, M.D., F.A.C.P.
Program Director

Keep the World in Balance

The child who has watched the miracles of new plants breaking through the earth in the spring; who has kept a silent vigil in observing a robin's nest; who has studied the stars and pondered the mysteries thereof; who has walked with Nature and talked with God, and stood in awe of the universe . . . has learned more than he'll ever learn from books. If he can retain his interest in the world, during those trying years of being polished on the grindstone . . . if he can look up to the heavens and down to the earth and keep his world in balance . . . he will surely be among the nineteen-out-of-twenty who will never spend time in a mental hospital.*

*James Fisher, M.D.: A Few Buttons Missing, 1951.

Preventive Medicine Seminar

A Preventive Medical Seminar will be held at St. Luke's Hospital, St. Paul, on Thursday, April 25th. The seminar will start with a general staff buffet luncheon at 12:30 and end with a 5:00 p.m. social hour. Contact: K. M. Lawler, M.D., Chairman, St. Luke's Hospital, St. Paul.

Blue Earth Valley Medical Society, April 17, Regular Meeting, Interlaken Golf Club, Fairmont, 7:00 P.M.

Kandiyohi-Swift-Meeker County Medical Society, April 18, Westwood Inn, Spicer, 7:00 P.M.

McLeod County Medical Society, April 18.

Twin City Urological Society, Town and Country Club, St. Paul, 6:30 P.M., April 19.

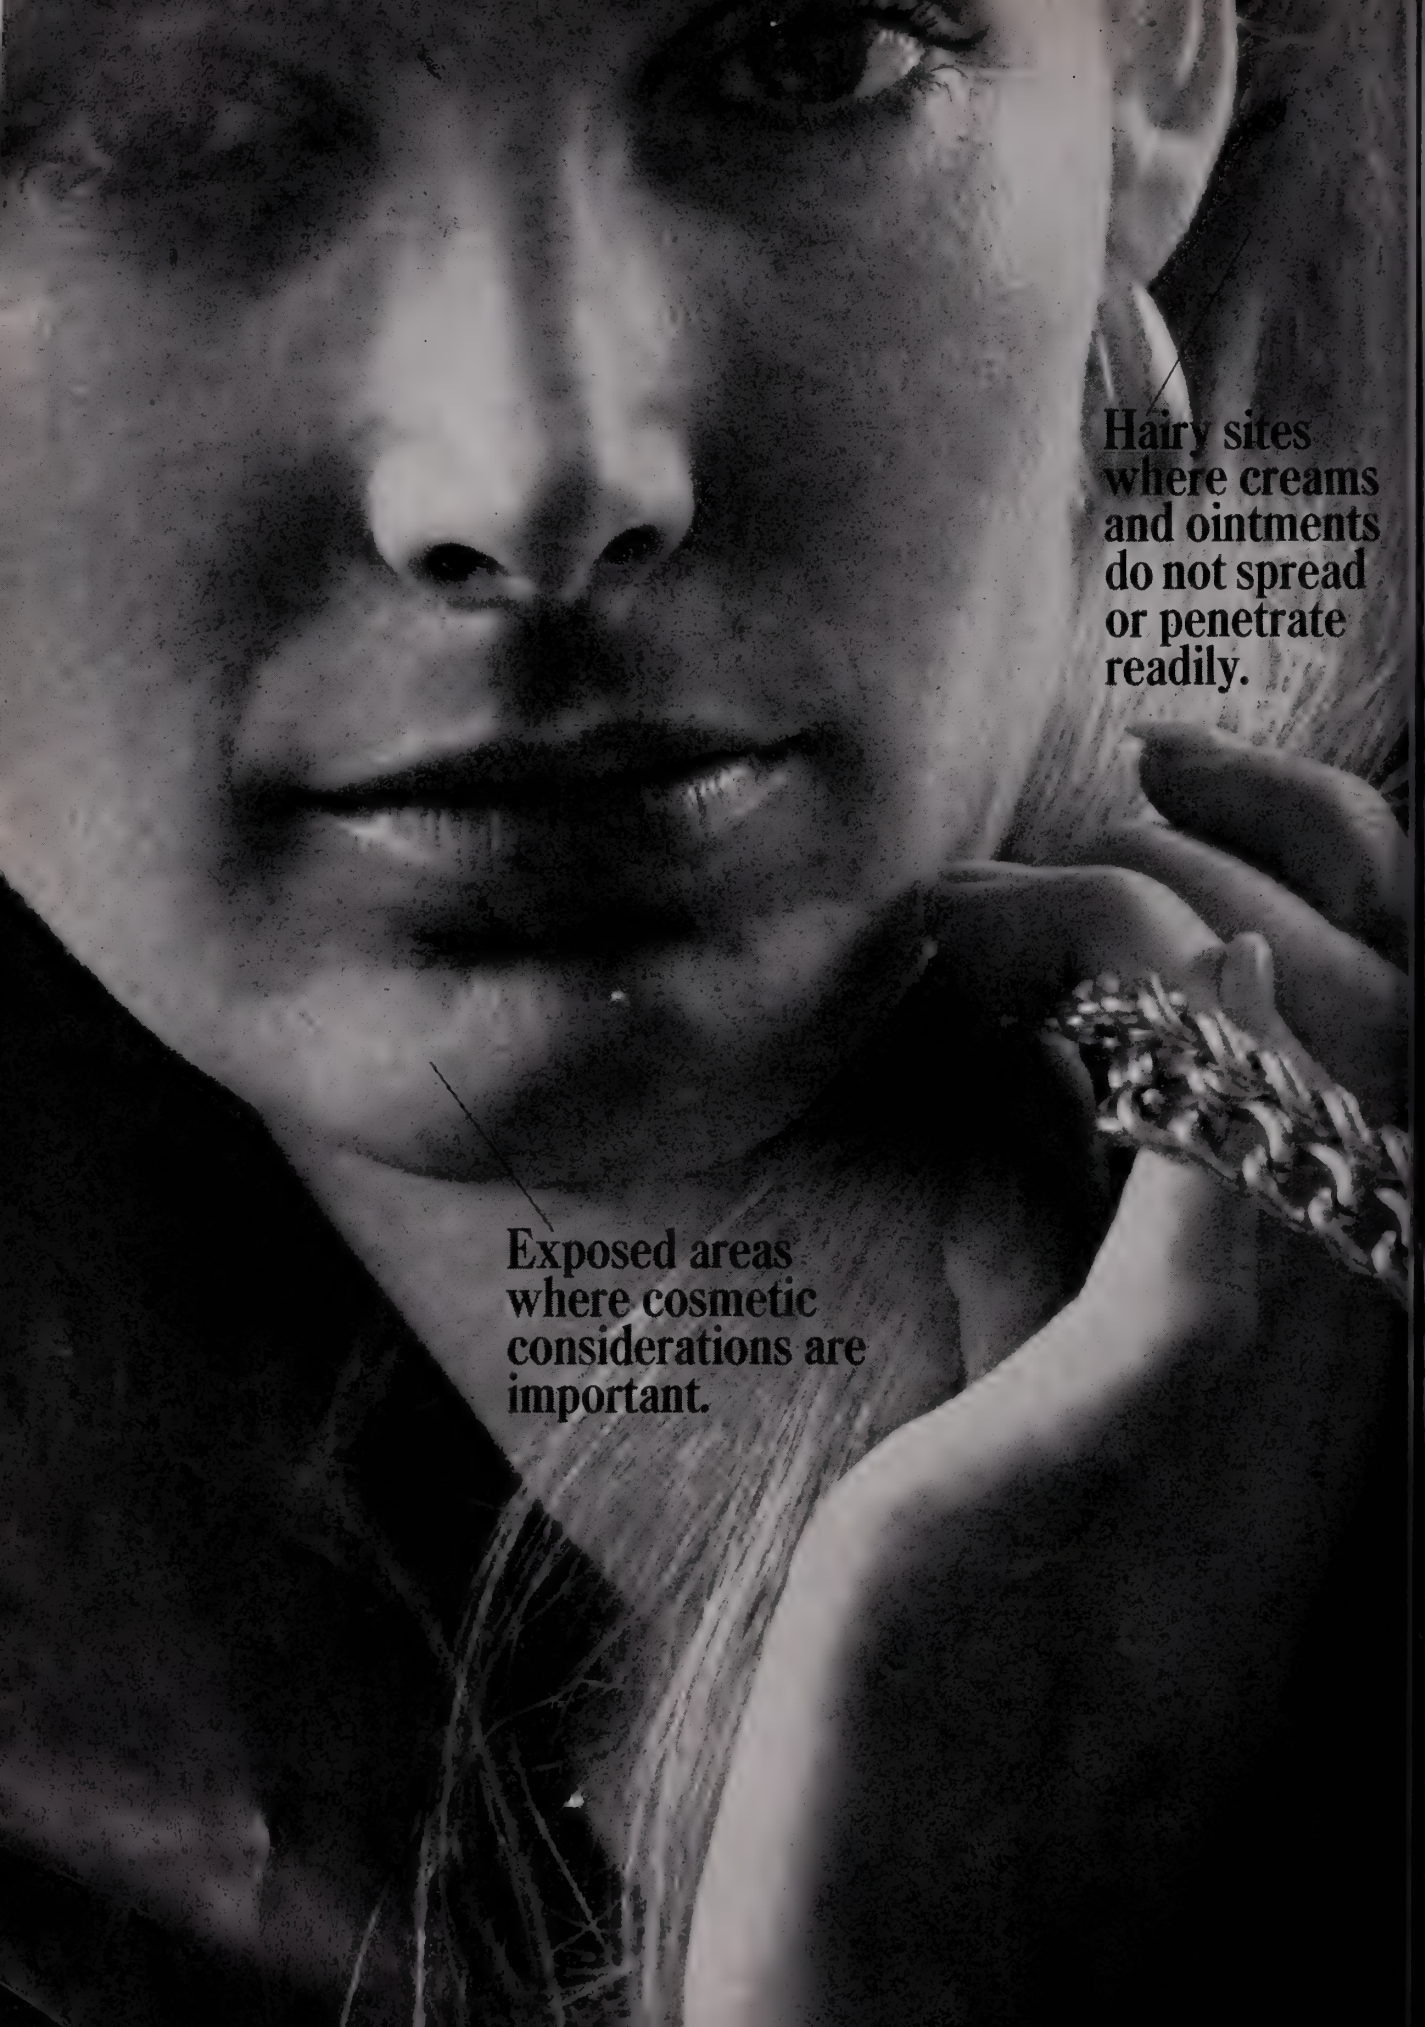
Blue Earth County Medical Society, April 22, Century Club, 8:00 P.M.

Minnesota Obstetric and Gynecological Society, April 27, Mayo Clinic, Rochester, 9:00 A.M.

Upper Mississippi Medical Society, Spring Meeting, St. Gabriel's Hospital, Little Falls, 2:30 P.M., April 27.

Ramsey County Medical Society, April 29, Regular Meeting, 1500 Lowry Medical Arts Building, 8:00 P.M.

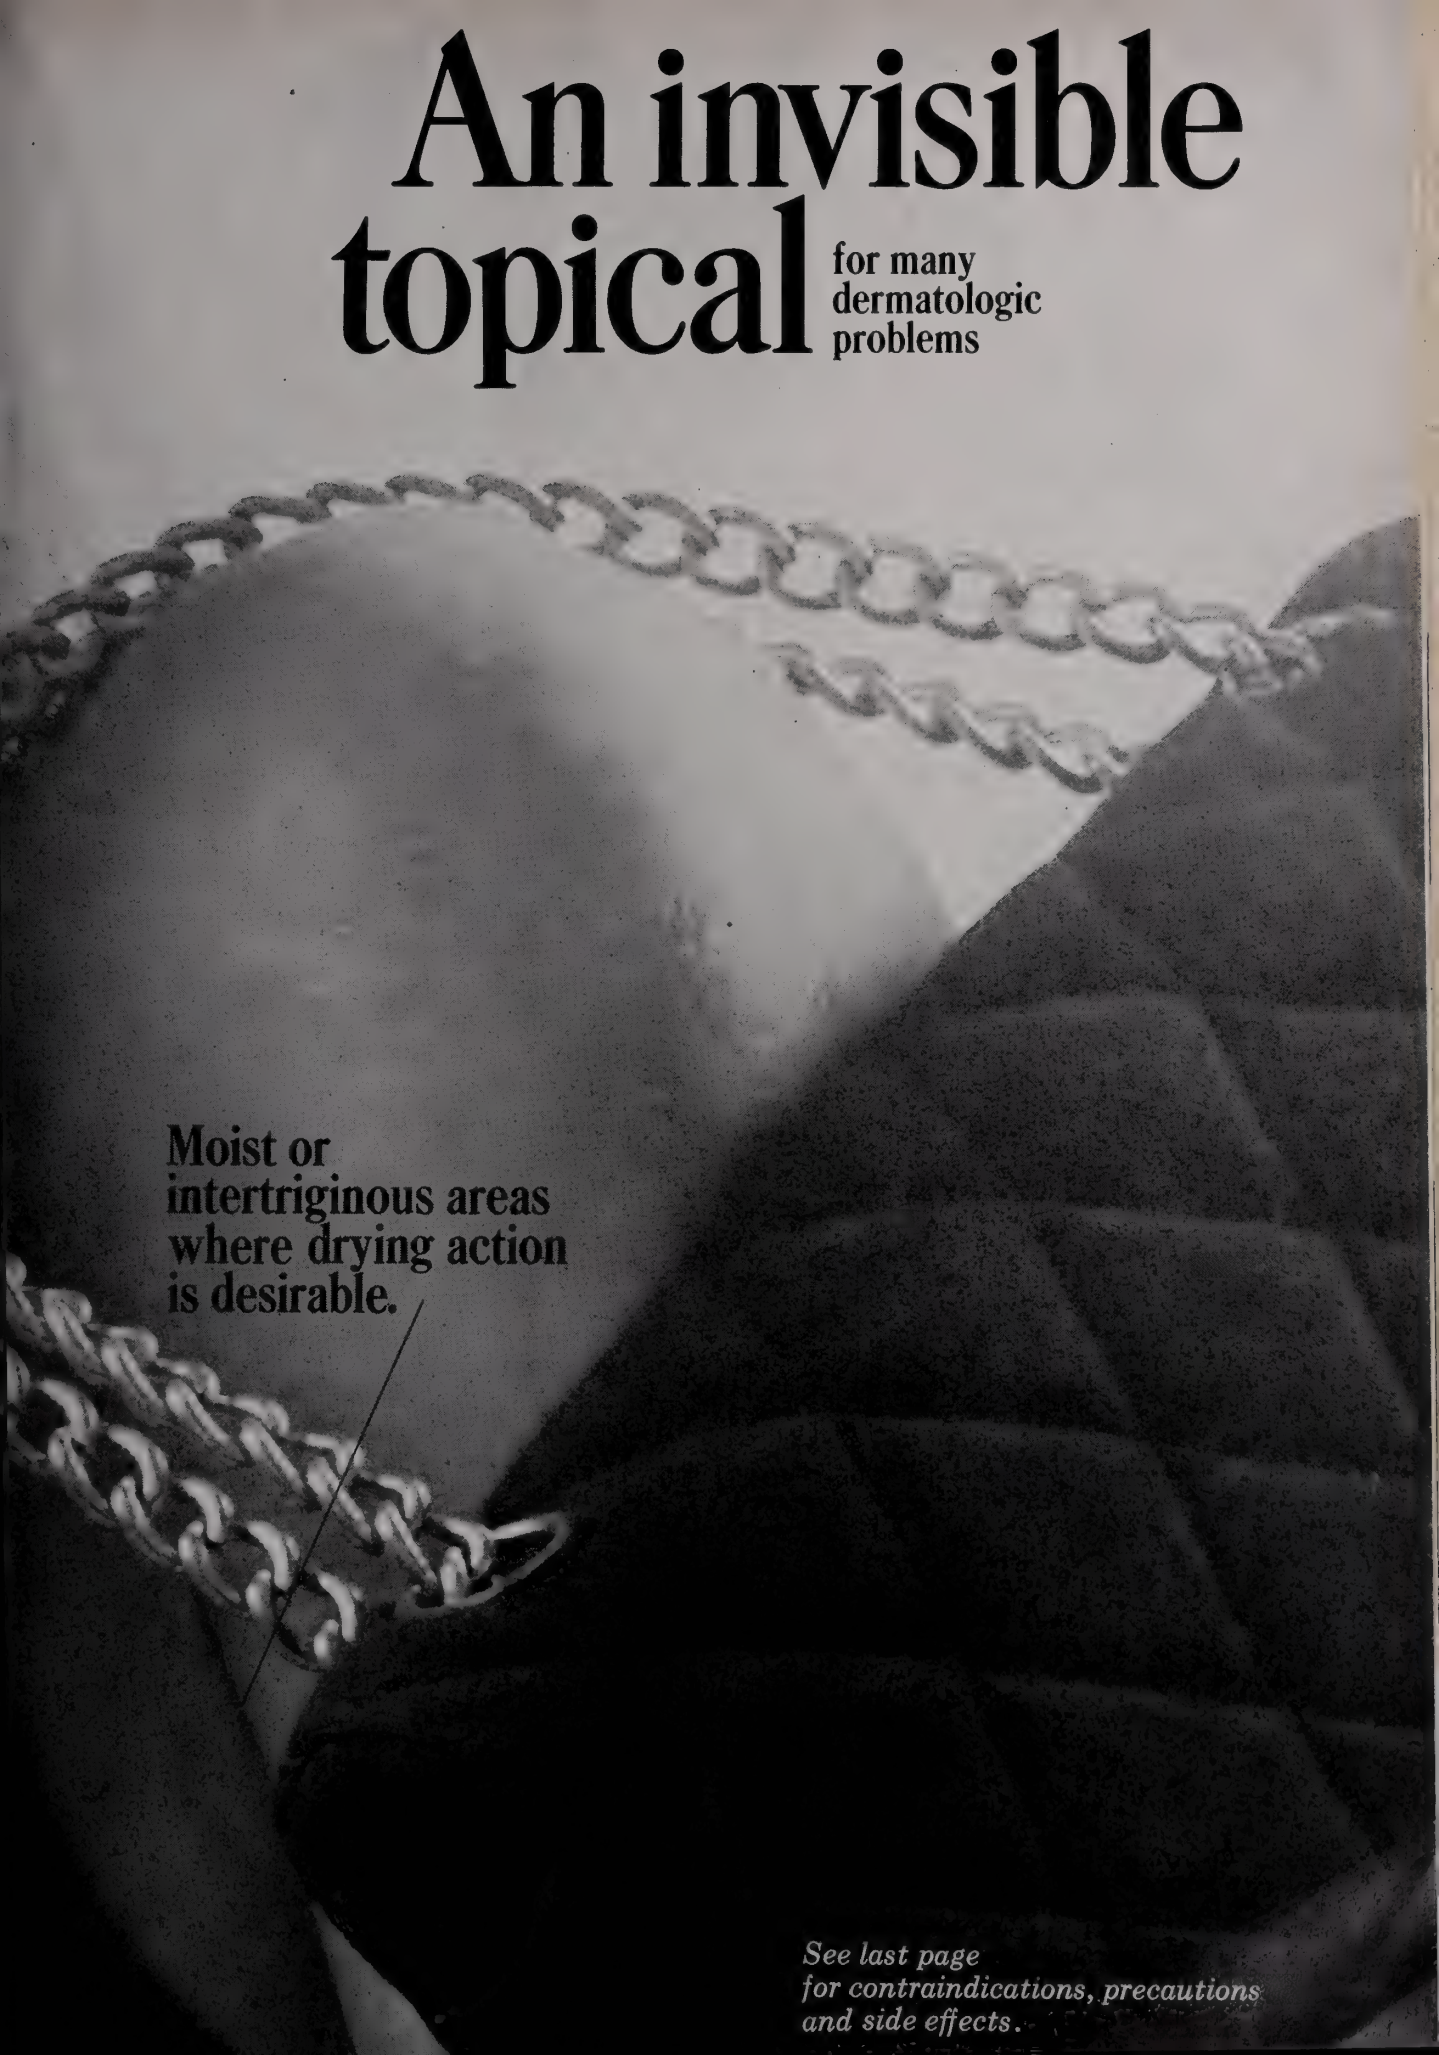
The Minnesota Thoracic Society and the Minnesota Respiratory Health Association announce a second award contest for medical students, interns and resident physicians in Minnesota.



(A) An award of $200.00 is offered for the best paper submitted by a senior medical student or intern on some aspect of respiratory disease, preferably based upon laboratory or clinical investigation.

(B) An award of $300.00 is offered for the best paper submitted by a resident physician based upon clinical or laboratory investigation in the area of respiratory disease.

Further information may be obtained from the Secretary. Entries should be submitted by September 1, 1968 to: David E. Dines, M.D., Secretary, Minnesota Thoracic Society, Mayo Clinic, Rochester, Minnesota.



L. E. Phillips Psychobiological Research Divisions of North Memorial and Mount Sinai Hospitals with The Minnesota Heart Association Symposium on Heart and Emotions. North Memorial Hospital auditorium, April 7, 1968. Afternoon and evening sessions (1:15 p.m. to 8:45 p.m.), with dinner being served at 5:30 in the hospital dining room. Attendance has been approved by the Academy of General Practice for 6 hours of Post-Graduate Study. Since the number of registrants will be limited, they will be accepted by acknowledgment in the order received. Contact Ralph Rossen, M.D., 588-0616, extension 301, or 339-1692, extension 596.

The Minnesota Symposium on Prevention in Cardiology. Reducing the Risk of Coronary and Hypertensive Disease. May 2nd and 3rd, 1968, Mayo Clinic, Rochester, Minnesota. Sponsored by: The Minnesota Heart Association, The Mayo Foundation and The University of Minnesota. Information available from: Henry Blackburn, M.D., Stadium Gate 27, University of Minnesota, Minneapolis, Minnesota 55455.

Hairy sites where creams and ointments do not spread or penetrate readily.
Exposed areas where cosmetic considerations are important.

An invisible topical

for many dermatologic problems

Moist or intertriginous areas where drying action is desirable.

See last page for contraindications, precautions and side effects.

Structurally unique topical steroid in propylene glycol vehicle produces rapid response in many dermatoses.

Synalar Solution produces rapid antiinflammatory, antipruritic action through its unique topical corticosteroid, fluocinolone acetonide. The propylene glycol vehicle provides additional benefits for therapy at problem sites where it is difficult to achieve contact between the lesion and medication – or where creams or ointments may make the lesions worse. Synalar Solution has proved particularly valuable in the symptomatic treatment of seborrheic dermatitis of the scalp, nasolabial folds, eyebrows, ears, and in flexural folds such as the axillae, inframammary, umbilical and anocrural areas. It has also been reported to achieve excellent results in the adjunctive management of atopic dermatitis, contact dermatitis, neurodermatitis, nummular eczema, psoriasis, and sweat retention syndromes in these problem sites.

Penetrates the hairy sites.

In many areas of the body, hair gets in the way of treating the underlying dermatitis. The propylene glycol vehicle of Synalar Solution permits penetration and dispersion at sites where creams and ointments do not readily penetrate. May be applied without matting of hair.

Ideal for moist or intertriginous areas.

Propylene glycol is strongly hygroscopic and is especially useful where sweat retention is a problem. Its low surface tension permits easy spreadability in difficult-to-treat body areas. A number of studies have also shown that propylene glycol has inherent antimicrobial activity.

Cosmetically acceptable for exposed areas.

The propylene glycol vehicle of Synalar Solution possesses many useful cosmetic properties. Clear and greaseless, it is not sticky or messy, will not stain clothing or skin. In exposed areas of the body where cosmetic appeal is important, Synalar Solution shows nothing but results.

Economical—a little goes a long way.

Because of the properties of propylene glycol and the milligram potency of fluocinolone acetonide, a small quantity of Synalar Solution goes a long way. Also, the prescription price of a 20 cc. plastic squeeze bottle of Synalar Solution is surprisingly low. Thus, your patients obtain economy with the proved efficacy of a potent, truly advanced topical corticosteroid.

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components.

Precautions: In some patients with dry lesions, the solution may increase dryness, scaling, or itching. Application to denuded or fissured areas, such as genital or perianal sites, may produce a burning or stinging sensation. If this persists and dermatitis does not improve, discontinue medication. Although propylene glycol has antiseptic activity, there should be careful initial evaluation and follow-up of infected sites. Incomplete response or exacerbation of lesions may be due to true infection, which requires susceptibility testing and appropriate therapy. On the other hand, saprophytic or low grade infections may clear spontaneously under the influence of Synalar Solution alone. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time.

Side Effects: Side effects are not encountered ordinarily with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions.

Availability: Synalar (fluocinolone acetonide) Solution 0.01% in a propylene glycol vehicle with citric acid as preservative. 20 and 60 cc. plastic squeeze bottles. *Also available:* Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

EMERGENCY ROOM PHYSICIANS: Kern General Hospital, Bakersfield, California, maintains active emergency service (40,000-45,000 visits/year) needs five full-time physicians for round-the-clock coverage. California license required. Negotiations made on the basis of fee-for-service or flat rate. Projected income, $25,000 annually per physician. Increases possible. Contact James Reavis, M.D., Director of Medical Services, 1830 Flower, Bakersfield, California 93305; telephone 805-323-7651.

FOR SALE: one examining table and contents, various instruments, baby scale, waiting room furniture, arm chairs, desk and chair, Thermofax copy machine, ultra-violet lamp, infra red light and stand, BMR machine lead screen, twin transilluminator-sinus, cast cutting instruments, electric stair-glide. Write: Mrs. W. E. Anderson, Clearbrook, Minn. 56634.

PRACTICE FOR SALE: Well established general practice in South Minneapolis serving an excellent community, within easy reach of the finest hospitals in the State. Very reasonable, low overhead. Splendid opportunity for solo or partnership practice. Write: MINNESOTA MEDICINE-397, 375 Jackson St., St. Paul 55101.

NEW DENTAL MEDICAL CLINIC, 5201 Bloomington Avenue South, Minneapolis 55417. Physician space available 1400 square feet. Contact: Dr. Roger K. Schroeder, 824-8957 (office) or 890-4690 (home).

PHYSICIAN WANTED: G.P. with G.P. residency or Internal Medicine training or Internist to join two busy G.P.'s in new, fully equipped office 25 miles from downtown Minneapolis, Minnesota. Accredited hospital. Salary open. Prefer military service completed. Write: MINNESOTA MEDICINE-398, 375 Jackson St., St. Paul 55101.

PHYSICIAN WANTED for Student Health Service. Eight physicians. Hospital associated. Salary adequate; excellent fringe benefits. Contact Gail A. Proffitt, M.D., Iowa State University, Ames, Iowa or phone 294-5801.

GENERAL SURGEON interested in some general practice to associate with a two-man partnership in a rich agricultural community in southern Minnesota. Modern hospital and new clinic building. Hunting, nine hole golf course, swimming pool. Salary open and full partnership as soon as desired. Write: MINNESOTA MEDICINE-399, 375 Jackson St., St. Paul 55101.

TWO PEDIATRICIANS: Opportunity for two pediatricians to begin practice together. Group association, Guarantee. College town of 35,000 in upper Midwest. Write: MINNESOTA MEDICINE-400, 375 Jackson St., St. Paul 55101.

OPPORTUNITY FOR CAREER in occupational medicine with large corporation. Multiple locations. Salary plus fringes. Immediate openings in three locations, one in Minnesota. Give rèsumè. Write: MINNESOTA MEDICINE-401, 375 Jackson St., St. Paul 55101.

What's New

Wyeth supplies first coral-snake antivenin! The first U. S. licensed and produced Antivenin to combat the North American eastern coral snake has been developed by Wyeth Laboratories and is now available in the nine states where coral snakes are found. The company has donated the Antivenin to the health centers in the nine states of Georgia, Florida, Alabama, Arkansas, Louisiana, Mississippi, North Carolina, South Carolina and Texas. Requests for Antivenin outside this nine state area must be referred directly to the National Communicable Disease Center, Atlanta, Georgia. Wyeth also produces the only licensed Antivenin for the poisons from pit vipers, rattlesnakes, copperhead and cottonmouth moccasins.

Loridine (cephaloridine), a new broad-spectrum antibiotic, is being introduced by Eli Lilly Company for the treatment of serious infection, including streptococci, staphylococci, hemophilus and colon organisma. It is recommended that the antibiotic not be used until the results of culture and sensitivity tests have been obtained and the renal function of the patient has been demonstrated to be adequate. Dosage in the excess of four grams daily has been associated with nephrotoxicity. Loridine is similar to Keflin, but intramuscular injection with Loridine is virtually free of pain.

Attendance

He has been a doctor a year now and has had two patients—no, three, I think—yes, it was three; I attended their funerals.—*Mark Twain*

Minnesota Medicine at a Glance

Atherosclerotic Cardiovascular Disease—Buchwald et al. Page 477

A rare and interesting case of true homozygous hypercholesterolemia is reported. Since the relationship of cholesterol and atherosclerosis is currently receiving a great deal of study and discussion, the implications of such a case are truly fascinating. The authors report the devastating effects of advanced atherosclerosis in a 14-year-old boy with this unique congenital disturbance, and of their attempt to ameliorate the problem. This case has served as a small, well defined, clinical experiment in the solution of the overall problem of atherosclerosis.

Precancer and Cancer of the Skin—Peterson Page 483

The chief difficulty concerns excess words and some difficult sentence structures. A number of word and sentence changes have been suggested. With these changes the paper is considered acceptable. There are six figures, but the photographs for the figures were not included with the paper submitted for review. The figures should be examined for quality.

The following is a summary: "There are a number of dermatological conditions which are considered to be precancerous. The differential between benign and malignant conditions is difficult in such skin problems as actinic keratosis, leukoplakia, arsenical keratosis, radiodermatitis, and pigmented nevi. The management of these difficult problems in skin disease is presented."

Incarceration of Transvenous Pacemaker Electrode—Bilgutay et al. Page 489

Temporary or permanent myocardial pacing by an intravenous electrode is a recognized therapeutic measure for multiple cardiac arrhythmias. Although removal of the pacemaker wire from the heart is usually not a problem, the authors describe two patients in whom removal was a problem. A simple technique of gentle traction by a one-half to two-pound weight proved effective. A successful removal may have saved the patients from a thoracotomy and cardiotomy or other complications of a retained electrode.

Errata

Abdominal Mass and Acute Leukemia—Clinical Path Conference. 51 :260, 1968.

Reference is made to two new drugs in the treatment of leukemia in my discussion. In referring to Daunomycin the text would suggest that Daunomycin is the same as L-Asparaginase, and these are of course two entirely different compounds. Apparently an oversight on my correction of the text led to their being made to seem synonymous, which they are not.

Robert A. Green, M.D.
Minneapolis, Minnesota

Porphyria 51 :49, 1968.

We neglected to correct the word "synthesis" fourth line up, left hand column, in the above editorial. It should be "synthetase."

115th Annual Meeting Issue
Minnesota State Medical Association

Dilantin®
(diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anticonvulsant drugs.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. ADVERSE REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred.
DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.
Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS 015R67

Lutrexin®

HW&D BRAND OF LUTUTRIN

3000 UNIT TABLETS

IN THE TREATMENT OF FUNCTIONAL DYSMENORRHEA AND SELECTED CASES OF PREMATURE LABOR AND 2ND AND 3RD TRIMESTER THREATENED ABORTION

■ LUTREXIN, the non-steroid "uterine relaxing factor" has been found to be useful by many clinicians in controlling abnormal uterine activity.

■ Literature on indications and dosage available on request.

■ No side effects have been reported, even when massive doses (25 tablets per day) were administered.

■ Supplied in bottles of twenty-five 3,000 unit tablets.

(In vivo measurement of Lutrexin on contracting uterine muscle of the guinea pig.)

HYNSON, WESTCOTT & DUNNING, INC. HW&D **BALTIMORE, MARYLAND 21201**

(LTR23)

...but his other symptoms:
functional somatic complaints, anxiety, insomnia, anorexia, feelings of guilt strongly suggest an underlying depression.

when the diagnosis is depression

ELAVIL® HCl
AMITRIPTYLINE HCl

Indications: Mental depression and mild anxiety accompanying depression.

Contraindications: Glaucoma and predisposition to urinary retention. Not recommended in pregnancy.

Precautions and Side Effects: Drowsiness may occur within the first few days of therapy. Patients should be warned against driving a car or operating machinery or appliances requiring alert attention. When depression is accompanied by anxiety or agitation too severe to be controlled by ELAVIL HCl alone, a phenothiazine tranquilizer may be given concomitantly. Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having varying modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Monoamine oxidase inhibitor drugs may potentiate other drugs and such potentiation may even cause death; permit at least two weeks to elapse between administration of two agents; in such patients, initiate therapy with ELAVIL HCl cautiously with gradual increase in dosage required to obtain a satisfactory response. Caution patients about errors of judgment due to change in mood, and that the response to alcohol may be potentiated. May provoke mania or hypomania in manic-depressive patients.

Side effects include drowsiness; dizziness; nausea; excitement; hypotension; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of schizophrenia which may require phenothiazine tranquilizer therapy; epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration or, rarely, transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of the mouth, blurring of vision, urinary retention, constipation; paralytic ileus; jaundice; agranulocytosis.

Careful observation of all patients is recommended. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Supplied: Tablets ELAVIL HCl, containing 10 mg., 25 mg., and 50 mg. amitriptyline HCl, bottles of 100 and 1000; Injection ELAVIL HCl, in 10-cc. vials, containing per cc.: 10 mg. amitriptyline HCl, 44 mg. dextrose, 1.5 mg. methylparaben, and 0.2 mg. propylparaben.

Before prescribing or administering, read product circular with package or available on request.

When it's more than a bad cold

your patient can feel better while she's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In bacterial/allergic u.r.i., ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the tetracycline-sensitive organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Average adult dosage: 2 tablets four times daily, given at least one hour before, or two hours after meals.
Contraindications: History of hypersensitivity to any component.
Warning: If renal impairment exists, even usual doses may lead to liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. Hypersensitive individuals may develop a photodynamic reaction to natural or artificial sunlight during use. Individuals with a history of photosensitivity reactions should avoid direct exposure while under treatment, which should be discontinued at first evidence of skin discomfort.
Precautions: Some individuals may experience drowsiness, anorexia, and slight gastric distress. If excessive drowsiness occurs, it may be necessary to increase the interval between doses. Persons on full dosage should not operate any vehicle. Use may result in overgrowth of nonsusceptible organisms. If infections appear during therapy, appropriate measures should be taken. Infections caused by beta-hemolytic streptococci should be treated for at least 10 full days to help prevent rheumatic fever or acute glomerulonephritis. Use of tetracycline during tooth development may cause discoloration of teeth.
Adverse Reactions: Gastrointestinal—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes (a case of exfoliative dermatitis has been reported); photosensitivity; onycholysis and discoloration of nails (rare). Kidney—rise in BUN, apparently dose related. Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. In young infants, bulging fontanels following full therapeutic dosage has been reported. This has disappeared rapidly when drug was discontinued. Teeth—dental staining (yellow-brown) in children of mothers given tetracycline during the latter half of pregnancy and in children given the drug during the neonatal period, infancy, and early childhood. Enamel hypoplasia has been seen in a few children. Blood—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. Liver—cholestasis (rare), usually at high dosage. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.

President's Letter

115th Annual Meeting

Dr. O. L. N. Nelson has kindly given me, as a past President, the opportunity to invite the members of the Minnesota State Medical Association to attend the Annual Meeting in Rochester during May 12 to 15.

In addition to the usual stimulating program which has been arranged for the entire meeting, there will be an interesting innovation at the annual banquet. Those of us who have had the honor of serving as your President have been impressed, when visiting our neighboring state associations, by the ceremony of induction of the Presidents.

In Minnesota, the incoming President quietly assumes office at midnight on New Year's Eve without any fanfare except that which may have been provided by his personal friends. This year, for the first time, our President will be honored by the presentation of a gold medallion which he may wear during his term of office.

A replica of the medallion in a bronze plaque will be awarded at the banquet to each of the 20 living past Presidents. We hope that all of them will be able to join you in this happy occasion on May 14.

J. M. Stickney, M.D.
Past President and Delegate
to the American Medical Association

In all this advance of science there is one grand, outstanding exception—the healing arts. All that cures or banishes disease, all that quenches human pain, and mitigates bodily infirmity, is welcome whatever view you take of religion, philosophy, or politics.—Winston Churchill, 1951

To live well we must have a faith fit to live by, a self fit to live with, and a work fit to live for.—Rev. Joseph Newton

A Bronchodilator Solution

Postoperative Use

ALEXANDER E. RATELLE, M.D.*
RICHARD J. WETT, M.D.**
HARLAN JORGENSEN, M.D.**
PAUL SCANLAN, M.D.**
Minneapolis, Minnesota

DURING RECOVERY from anesthesia, the surgical patient requires intensive care. The residual effects of anesthesia must be ablated in order that the patient regain his productive cough, re-establish his respiratory drive to the normal rate and thus assure that hypoxia or hypercarbia is corrected. An early return of normal ventilation reduces the incidence of atelectasis and other systemic complications. These efforts directed towards improving ventilation in the immediate post-surgical period should not, however, cause an increase in patient excitation with subsequent increased metabolic needs; for then the net result might be a decrease in blood and tissue oxygen tension.

We have for sometime used a bronchodilator solution, Bronkosol®†,[1-5] in the pre- and post-operative period to aid the patient to more rapidly recover normal ventilation. The use of this agent appeared to improve tolerance to intubation. Approximately 25,000 doses of the drug had been used for all age groups and all types of surgical patients. With few exceptions, our patients are intubated under demerol, pentothal, galamine and nitrous oxide anesthesia. The nitrous oxide and demerol are used as the major anesthesic agents.[6]

Objectives of Study

In order to check our clinical impressions of the effectiveness of the bronchodilator solution, studies were designed to give information on the effect of Bronkosol inhalations on the surgical patient in the immediate postoperative period. We were primarily interested in its effect on respiratory rate, minute volume, pulse rate and blood pressure. In addition, we checked first, whether the type of surgery performed had any significant effect on these measurements; and second, what the effects of Bronkosol were in patients with hyperten-

sion. Drug-related systemic effects were recorded, if observed.

Material and Methods

One hundred forty-nine patients were chosen from the general surgery schedule. Criteria for inclusion were: (1) major surgery, (2) reduced minute respiratory volume, (3) depressed respiratory rate, (4) symptoms or laboratory findings of respiratory acidosis, or (5) any combination of these. Patients selected were classified according to the following surgical procedures:

	Procedure	Patients
I	Head and Neck	16
II	Chest	7
III	Right Upper Quadrant	21
IV	Left Upper Quadrant	41
V	Right Lower Quadrant	21
VI	Left Lower Quadrant	15
VII	Genitourinary	26
VIII	Leg and Hip Surgery	2

A dosage of 20 "squeezes" from a De Vilbiss #40 nebulizer was used for patients under 18 years of age and 30 inhalations for patients over 18. Trials, by the personnel administering the solution, indicated that approximately 4 drops (.26 ml.) of Bronkosol solution was nebulized with 20 squeezes and 6 drops (.40 ml.) with 30.

Control readings were made of the pulse rate and blood pressure immediately before administration of Bronkosol and then at 15-minute intervals for one hour. The "greatest change" in either direction was chosen as the maximum effect and was recorded. For instance, if fluctuations in blood pressure included a reduction of 10 mm/Hg. from control, followed by an increase of 15 mm/Hg. above control, only the 15 mm/Hg. figure would be recorded as the major effect.

Results

Table 1 presents the distribution of patients by initial pulse, blood pressure and amount of change in blood pressure.

Pulse Rate

Pulse rate changes less than 10 beats per minute from control occurred in 107 of the 149 patients; the rate increased more than 10 beats per minute in 21 patients and de-

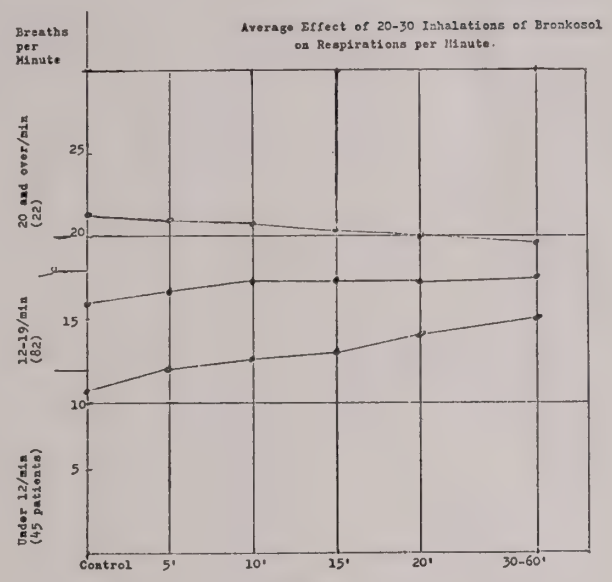
The calculated value determines the p value. The p value is the level of significance of the difference between the means.

creased more than 10 beats per minute in 21 patients.

Blood Pressure

Inhalation of Bronkosol produced only a moderate effect on the systolic blood pressures (mean pre-treatment systolic pressure 140 mm/Hg.). As indicated in Table 1, only 17 patients had an increase or decrease greater than 20 mm/Hg. from control. Diastolic pressures changed less than 10 mm/Hg. from control in 108 of the 149 patients.

A summary of the effect of Bronkosol on pulse and blood pressure is presented in Table 2, along with levels of significance. Note that the lower initial values tended to increase and the higher initial values tended to decrease.



Respiratory Rate

The effect of Bronkosol on respiratory rate is presented in the illustration (Figure).

Note that the respiratory rate tended to decrease steadily in those patients with a control rate of more than 20. In contrast, the respiratory rate in patients with control values between seven and 12 breaths per minute increased noticeably. There was no significant effect on the group with control readings between 13 and 19 breaths per minute. The type of surgery was not significantly correlated with the respiratory rate in this series.

Respiratory Volume

Respiratory volume was measured using the Wright Expiratory Flowmeter. One-minute samples were measured at control, then at 5′, 10′, 15′, 20′ and 30-60′ after inhalation of

Figure

Bronkosol. (Twenty-four of the original 149 patients were eliminated from tabulations of minute volumes because of insufficient data or changes unrelated to Bronkosol therapy.)

The effect of ventilation of 20 or 30 breaths of nebulized Bronkosol on minute volume is presented in Table 3.

A significant increase was noted in those patients with depressed pre-treatment minute volumes. No significant difference was found between the groups treated with 20 as compared with 30 inhalations, although the difference tended towards significance in increased minute volume for the patients treated with 30 inhalations.

Control Group

previously with those of untreated patients, 30 similar post-surgical patients were chosen and the same measurements recorded. Except for elimination of the Bronkosol inhalations, the care of the patient remained the same.

Table 4 presents the summary of measurements of pulse rates and blood pressures in the control group.

Table 5 presents the summary of respirations per minute for the control group.

Table 6 presents the changes in respiratory minute volume for the control group.

Discussion

The anesthetized patient, whose respiration is being controlled, loses the natural reflexes of cough, sigh, and respiratory stimulation. In addition, inhalation of dry anesthetic gases causes chemical and physical irritation of the airway. As a result, the airway may be obstructed by dehydrated secretions, patches of atelectasis caused by absorption of oxygen or anesthetic gases behind the mucous obstructions, bronchial spasm and decrease in elastic compliance. In addition to these pulmonary complications, residual amounts of circulating sedatives and relaxants and the physical restriction of dressings tend to limit depth and frequency of respiration. Any technique which aids elimination of the anesthesia-related complications and restoration of normal respiratory reflexes and function hastens the postoperative recovery of the patients. Inhalation of Bronkosol, adequate replacement of fluid loss, and humidification of the inspired air are helpful and easily administrated.

It is our impression that these patients recovered more rapidly from their anesthetic state when the bronchodilator was used in the

immediate postoperative period. Their respirations were stronger and more regular and title volume increased. While further studies are under way to measure the effects of bronchodilator therapy on compliance and perfusion, we believe that airway resistance is reduced and oxygenation improved.

Tolerance to Bronkosol therapy has been good with only moderate and usually beneficial effects on pulse and blood pressure. There appears to be no contraindication to the use of this agent in the patient with hypertension. This therapy has been used in patients with pre-existing cardiac conditions. Selected patients were monitored via cardioscope before and after the administration of Bronkosol. There has been no evidence, to date, of adverse cardiac effect.

We would encourage further study of the pre- and post-surgical use of bronchodilator and positive pressure therapy. Techniques which improve respiratory efficiency pre-surgically and help to restore normal pulmonary function in the postoperative period should be investigated and, if found successful, regularly employed.

Summary

One hundred forty-nine patients were treated in the postoperative recovery room with 20-30 inhalations of Bronkosol with the aim of increasing respiratory rate and depth as well as speeding recovery from the effects of anesthesia. The results of this therapy were measured at fixed intervals for one hour. Respiratory rate and minute volume tended to increase in the low and low-normal group. Pulse and blood pressure were not significantly affected. There was no evidence that the type of surgery performed significantly affected the post-surgical control recordings of pulse, blood pressure, respiratory rate or volume.

The administration of this bronchodilator solution during the post-surgical recovery period is well tolerated and appears to be useful in speeding recovery from anesthesia.

Jackson's Syndrome

This syndrome is characterized by unilateral involvement of the last three cranial nerves: the vagus, spinal accessory, and hypoglossal. Their involvement may be recognized from the combined symptomatology consisting of ipsilateral paralysis of half of the soft palate and larynx, paralysis of the sternocleidomastoid and trapezius muscles, and hemiatrophy of the tongue. Jackson described this syndrome in 1864. Although usually caused by an intracranial lesion, it may sometimes arise in one lateral half of the medulla oblongata at a level in which are involved the hypoglossal, ambiguus, and spinal accessory nuclei. The lesion is usually vascular in origin.

When down in the mouth, remember Jonah: he came out all right.—Thomas Edison

Shakespeare's Doctors

Dr. Cornelius

Questions raised but left unanswered constitute one of the most intriguing of literary devices to retain the reader's interest long after his perusal of the script. Just such an engaging speculation arises in "Cymbeline": what was the nature of the drug Dr. Cornelius prepared at the behest of the Queen?

Shakespeare's court physicians had to be artful diplomats as well as doctors, since they must sometimes have been required to follow orders that challenged or compromised their moral integrity.

When the Queen in "Cymbeline" commanded Dr. Cornelius to compound a poison for her to administer experimentally to lower animals, he was faced with an ethical dilemma: adherence to court protocol versus his conscience, which revolted at the Queen's assignment, particularly because he rightly suspected her of ulterior motives. Without qualm, he had often compounded for her various innocuous cosmetics and unguents. But poison! That was another matter!

How did Dr. Cornelius resolve this moral conflict? He tempered obedience with discretion by providing the Queen with a drug that would appear to be lethal but act only as a temporary anesthetic.

> I do not like her. She doth think she has
> Strange lingering poisons. I do know her spirit,
> And will not trust one of her malice with
> A drug of such damned nature. Those she has
> Will stupefy and dull the sense a while,
> Which first, perchance, she'll prove on cats and dogs,
> Then afterward up higher; but there is
> No danger in what show of death it makes,
> More than the locking-up the spirits a time,
> To be more fresh, reviving."*

We cannot but speculate on what the drug may have been. When administered to Imogene it was "murderous to the senses"; further, it made her "primrose-pale" and "stark." While a small dose of chloral could have acted as a narcotic, it would hardly have had such a drastic effect as to make Imogene "primrose-pale" and "stark." Could the drug have been chloroform? But chloroform was not discovered until 1831!

Did Shakespeare foresee the advent of chloroform? Did he possess a quality of seership that provided him with telescopic vision into the future?

*Cymbeline I, 5.

Cured by Shame

The patient was a woman in the King's household who, while bending down to lay the table, was attacked by a sudden "rheumatic swelling of the joints," and was unable to assume an erect posture. The King's physician, being commanded to cure her, and having no medicaments at hand, had recourse to "psychic treatment" and, by removing first her veil and then her skirt, called to his aid the emotion of shame, whereby a flush of heat was produced within her which dissolved the rheumatic humour, so that she stood upright completely cured.*

The Cytologic Evaluation of Early Pregnancy

A Review

LEON L. ADCOCK, M.D.
Minneapolis, Minnesota

VARIOUS TECHNIQUES are available to the physician for evaluating the status of early pregnancy. These techniques involve a direct or indirect estimate of the pregnancy hormone production. Chorionic gonadotropin and progesterone are the two major hormones produced in early gestation. The trophoblast elaborates chorionic gonadotropin, which acts on the corpus luteum to maintain its production of progesterone. Quantitation of the levels of chorionic gonadotropin in early pregnancy is performed only in specialized laboratories. Progesterone production can be estimated by the amount of pregnanediol, its major metabolite, excreted in the urine and by vaginal cytology. The determination of pregnanediol is difficult, expensive and time-consuming. Vaginal cytological evaluation of progesterone, although possibly not as accurate an index as pregnanediol determination, has a number of advantages.[1-5] Vaginal smears are inexpensive and easily obtained, and the results are available with little delay. Only the most recently exfoliated vaginal epithelial cells are of value in the estimation of the hormonal background of the pregnancy. Cells are obtained from the lateral wall of the proximal vagina with a tongue blade or a moistened cotton-tipped applicator.

Differentiation of Vaginal Epithelium

Proliferation of the vaginal epithelium takes place only in the basal layer; differentiation occurs in the parabasal, intermediate, and superficial layers. Desquamation may occur from any layer. Cellular maturation at the time of desquamation reflects the total hormonal environment affecting the vaginal epithelium. A quantitative estimate of the degree of maturation can be obtained by various indices of the exfoliated cells. The maturation index consists of a differential counting of parabasal, intermediate and superficial cells on the smear. Other indices commonly used are the

karyopyknotic* (pyknotic) index and the eosinophilic (acidophilic) index. Only cells which have intact margins and occur singly or in small clusters are evaluated. Superficial cells with pyknotic nuclei are counted in the karyopyknotic index. Other aspects of hormonal evaluation are judged by the appearance of the exfoliated vaginal cells and the presence of other cells on the smear, such as erythrocytes, histiocytes, decidual and trophoblast cells, Trichomonas vaginalis, Candida albicans and virus inclusion bodies.

The degree of maturation of the exfoliated cells depends on the ability of the vaginal mucosa to respond and the type and quantity of hormonal stimulation. Surgical or radiation damage may alter the response of the vaginal mucosa to hormonal stimulation. Infection, easily recognized by the presence of other cellular structures in the smear, also alters the vaginal mucosa and its ability to respond. Hormonal abnormalities and drugs may likewise affect the vaginal mucosal response and hence the cells that are exfoliated.

Characteristic Hormonal Effects on the Vaginal Mucosa

Estrogen Effect

Endogenous or exogenous estrogen produces proliferation and maturation of the vaginal epithelium with desquamation of superficial cells. These cells have rectangular, transparent cytoplasm with pyknotic nuclei, occur singly, and lie flat on the smear. Only occasional Döderlein bacilli and leukocytes are present. Quantitative estimates are satisfactory indicators of estrogen effect. The karyopyknotic index is most frequently used, as it is relatively uninfluenced by technical errors.[6] Estrogen effect on the vaginal mucosa may be seen alone or with that of progesterone.

Progesterone Effect

Progesterone also has a marked effect on the vaginal mucosa, but this effect is never found in the normal woman unless there is simultaneous estrogen stimulation. Progesterone, with estrogen, results in the differentiation and exfoliation of intermediate cells which also have rectangular, transparent cytoplasm but contain vesicular nuclei. When progesterone effect predominates, the exfoliated intermediate cells are found in clusters, the cell margins are folded and indistinct and Döderlein bacilli and leukocytes are numerous.

Vaginal Cytology in Pregnancy

Early Pregnancy

The hormonal status of the pregnancy is reflected by vaginal cytology.[7,8] In the first trimester the vaginal cytologic changes are the result of hormones produced primarily by the corpus luteum. Because hormone production may fluctuate, the vaginal smear may vary to a moderate degree and still be normal. During the second and third trimesters the vaginal epithelium responds to hormone production of the placenta.

In the luteal phase of a normal menstrual cycle, there is proliferation of cells in the intermediate cell layer. Regression follows if conception does not occur. With pregnancy, the proliferation of the intermediate layers continues and the cytoplasm of the intermediate cells fills with glycogen.

Ten Weeks Gestation

A normal pregnancy smear is dependent upon the production of large quantities of estrogen and progesterone, the effect of the latter predominating.

After approximately ten weeks gestation, glycogen is usually present in the cytoplasm of the intermediate cells and causes condensation of cytoplasm at the cell borders which then appears as a thickened cell membrane. The nucleus is frequently flattened and eccentrically located at the cell margin. These changes characterize the pregnancy or navicular cell.[9] Only intermediate and superficial cells are exfoliated in a normal pregnancy. The parabasal cells, which are small and round or oval, have deep-staining cytoplasm, and vesicular nuclei are not normally found on a pregnancy smear. In the first trimester the karyopyknotic index progressively decreases and should be less than 30 percent. After the first trimester it is

*See Test Your Word Score Page 649.

under 10 percent. Superficial cells may have folded cell margins (Table 1). Cytolysis is common in pregnancy and, although not a poor prognostic sign, makes hormonal evaluation difficult. Cytolysis is usually the result of infection and may be eliminated by local vaginal antibiotic therapy.

   5. Leukocytes and Doderlein bacilli

Dead Fetus

The vaginal smear may arouse suspicion that the patient is pregnant; but in a smear without the usual findings, pregnancy is unlikely. When the status of a pregnancy is in doubt, exogenous estrogen in moderate dosage will not change the smear if the gestation is normal.[7] If the *conceptus* is dead and the placenta no longer functioning, exogenous estrogen will cause an increase in exfoliated superficial cells and therefore in the karyopyknotic index. Smears in some non-pregnant patients may be similar to those of pregnancy; hence quantitative estimates are of minimal help.

Castrated and Menopausal Women

Smears from castrated young women and menopausal patients also have only occasional superficial cells but do not show the other effects of progesterone. Similar smears are found in patients with amenorrhea due to low follicle-stimulating hormone production. Because progestogen treatment produces cells which on the smear are indistinguishable from those of pregnancy, the cytologist must have clinical data if the vaginal smear is to be interpreted adequately.

Serial vaginal smears are of greatest value in the evaluation of patients who have had previous spontaneous abortions, who have clinical signs of a pregnancy abnormality, who are receiving hormonal therapy, or who have other complicating disease which increases the risk to the fetus.

Threatened Abortion

The vaginal smears of patients with threatened abortion due to hormonal abnormalities have an increasing karyopyknotic index, thinning and separation of the intermediate cells, and disappearance of navicular cells and Döderlein bacilli (Table 2). Because cytologic changes in a hormonally-disturbed pregnancy appear before the clinical signs and symptoms, the values of cytologic evaluation in certain asymptomatic patients is obvious. Smears from patients with inevitable abortion show the findings of a hormonally disturbed pregnancy as well as erythrocytes, histiocytes and occasionally decidual and trophoblast cells.

TABLE 2
Pregnancy Cytology
Hormonally Disturbed Pregnancy

A. Karyopyknotic index
   1. Increasing in first trimester
   2. Greater than 30% in first trimester
   3. Greater than 10% after 14 weeks
B. Thinning and separation of cell clusters
C. Disappearance of navicular cells
D. Disappearance of Doderlein bacilli

Missed Abortion

The vaginal cytology of missed abortion is usually characteristic. In addition to the cytological pattern associated with threatened abortion, increasing numbers of parabasal cells are found. With delay in expulsion of the products of conception, there is a gradual shift in the type of cell that indicates a return to a predominantly estrogen effect. Because progesterone or progestogen treatment does not alter the cytologic picture in missed abortion, the vaginal smear is of value in determining which patients carry viable pregnancies.

Induced Abortion

In a spontaneous abortion the decreasing progesterone effect precedes the appearance of clinical signs. When the abortion has been induced, however, the corpus luteum, the placenta, or both are usually functioning normally until the moment of interruption. A vaginal smear obtained at this time or shortly thereafter will be normal except for the presence of

erythrocytes, leukocytes, and possibly decidual and trophoblastic cells. The regressive changes in the vaginal smear of an induced abortion usually occur five to seven days after the interference.

Prognostic Significance

A vaginal smear obtained on the initial prenatal examination is of prognostic significance.[4,6,7,10] Over 95 percent of the patients with normal vaginal cytology and no clinical abnormalities will deliver a living viable infant. Those with normal vaginal cytology who do have clinical evidence of threatened abortion also have a good prognosis. An abnormal smear from a patient without clinical evidence of threatened abortion indicates an increased risk for the fetus, a successful outcome occurring in about 65 percent of these cases. However, when vaginal cytology is abnormal and clinical signs of threatened abortion are present, only about 30 percent will deliver living viable infants.[7] Serial smears therefore are desirable for more accurate evaluation.

Discussion

A number of studies have correlated vaginal cytology with pregnancy hormone excretion.[1,3,5] Chorionic gonadotropin excretion directly reflects the condition of the trophoblast. Urinary pregnanediol excretion and vaginal cytology estimate production of progesterone by the corpus luteum in early pregnancy and by the placenta in the last two trimesters. After the 20th week, maternal estriol excretion indicates the well-being of the fetus. The evaluation of chorionic gonadotropin, pregnanediol and estriol excretion, as well as vaginal cytology, would give the most accurate prognostic estimate for a pregnancy as well as an indication of the site of the abnormality. Changing of the vaginal smear in abortion reflects a disturbance in estrogen-progesterone balance rather than an increase in estrogen activity.[11]

References may be secured from the author or the reprints.

Although 20 percent of all pregnant women bleed in early pregnancy, only one half of these will abort. Thus bleeding is not always an indication of an abnormal gestation and a sign of impending abortion. Germ-plasm defects, chromosomal abnormalities and non-hormonal factors are responsible for the majority of these early pregnancy losses. Hormonal abnormalities probably account for only 5 percent of all spontaneous abortions.[10] Only in this group with hormonal abnormality is the vaginal smear of value, as the smear pattern may identify this problem in sufficient time to salvage the pregnancy with appropriate hormonal replacement therapy. Treatment with hormones is wasted on threatened abortion due to any other etiology. Prognosis for pregnancy is poor only among those who have had three or more consecutive abortions. Hormonal therapy not only cannot improve the salvage in the great majority of these patients but may result in a missed abortion. When therapy is associated with an improved vaginal smear, the prognosis is excellent. In a non-viable pregnancy, estrogen therapy results in an increase in the karyopyknotic index, whereas progesterone and synthetic progestogens do not affect it. The prognosis is good only if the smear returns to normal.

Conclusion

The vaginal smear offers the clinician an available tool with which to evaluate the hormonal status of early pregnancy. Cells for the smear are readily obtained. Cell studies can be repeated frequently, are relatively inexpensive, and are available with little delay.

Vaginal smears are of prognostic value if serial studies are obtained from those patients who have had previous pregnancy losses, who have clinical signs of threatened abortion, and who are receiving hormone therapy. Hormone therapy, although commonly used, has limited application and may be expected to improve fetal salvage in only the small percentage of patients with threatened abortion secondary to a hormonal deficiency.

Silence

Better to remain silent and be thought a fool than to speak out and remove all doubt.—Abraham Lincoln

Autogenous Tooth Transplantation*

HOWARD P. BOLLER, D.D.S.
Encino, California

TISSUE GRAFTS and transplantation of various organs or body tissues are common and well established practices in medicine and surgery and also in the fields of dentistry and oral surgery. Skin and bone grafts about the mouth and jaws have been as common to oral surgery as tissue grafts have been to general surgery, and more recently there have developed techniques for the transplantation of teeth. Certainly if some tissues or organs can be transplanted, why not a tooth?

Stories have been written in the early days of medicine and dentistry about a tooth being removed from one person and implanted in the jaw of another, but the length of time for retention or service of these implanted teeth was usually omitted. It is known that this procedure cannot be successful, as the implant will be rejected by the recipient tissue and be exfoliated or absorbed.

Vital Tooth Buds

The Wisdom Tooth

There is a type of tooth transplant that has been successful: the autogenous transplant of vital tooth buds. Although any tooth in the proper stage of development theoretically might be transplanted, the most common and useful transplant is the third molar, or wisdom tooth. During the teen ages the third molars are beginning to develop their roots and the eruption process begins; in many instances, however, there seems to be insufficient room for these last molars to erupt, thus resulting in impacted and non-functioning teeth. Since various complications frequently result from such impacted teeth, it is advisable to have them removed surgically.

The Six year Molars

The first molars are probably the most important individual teeth and are referred to as the "keys to occlusion." But since they

*Presented at Northwest Medical Association Meeting, Sun Valley, February 1968.

Fig. 1—Impacted molar to the left and carious third molar to the right, pre-op.

Fig. 2—Tooth transplant three days post-op, roots incompletely grown.

Fig. 3—Tooth transplant five years post-op with caries in neglected second molar.

erupt at the early age of six years when oral hygiene and proper nutrition are difficult problems, these teeth have a high mortality rate through dental caries. Deterioration may continue if they are left untreated until the mid-teens and finally, one or more of these first molars may need to be extracted.

Thus the situation is frequently presented where an important tooth must be removed due to caries and infection, and a healthy but malpositioned tooth may be transplanted and become useful.

Selection for Autogenous Transplant

Autogenous transplant cases should be selected carefully. There are certain conditions that must be met in order to insure success. (1) The transplant must be a developing tooth with the roots only partially complete. (2) There must be no acute infection. (3) The developing root apices with their vital embryonal membranes must be undisturbed. (4) Near isothermic and isotonic conditions must be maintained during transplantation. (5) There must be adequate space to receive the transplant and this space must be maintained during eruption. (6) Some method of retention and protection of the transplanted tooth during healing must be provided.

Developing Tooth Bud

Fully formed teeth receive their nourishment and vitality by means of small vessels and nerves entering the foramina at the apical ends of the roots, but these vessels and nerve connections are not established until the root is almost completely developed. The developing tooth bud receives its nourishment primarily from the dental follicle in which it grows and from surrounding bone. Therefore the incompletely developed tooth can be carefully moved to a new site and will establish the necessary vascular supply in an organizing blood clot around the transplant.

The Follicular Sac

It has been proven that calcification of the crown is complete by the time two to three millimeters of root have developed. At this stage, the follicular sac around the crown, which is usually injured in the process of re-

moving the transplant, is no longer needed and may be removed. Continued growth depends upon the placement of the transplant at the proper depth and upon allowing growth by eruption into functional occlusion. Vitality depends upon the re-establishment of the vascular supply to the dental pulp and periodontal membrane attachments. Innervation may or may not occur in transplants; but this is not important.

Fully Formed Teeth

Transplanting fully formed teeth has been attempted, but ultimately root resorption occurs even though the procedure is an autogenous transplant. Vascularization essential to maintain a vital tooth is difficult or impossible to re-establish in a fully formed tooth; therefore, tooth structure not receiving a nourishing vascular supply will decompose and become infected. This has occurred also in reimplantation of traumatically avulsed teeth. Even though root-canal sterilization and filling with an inert material has been carried out for these avulsed teeth, resorption will take place and the reimplant will ultimately fail.

The Technique

The surgical procedure for these transplants is basically a combination of two operations: extraction of a diseased tooth, and surgical removal of the impacted and unerupted tooth bud to be placed in the prepared site of the removed diseased tooth.

Removal of the Tooth Bud

A typical case of a lower third-molar (wisdom tooth) bud transplanted to the first molar site is carried out as follows: An incision through the mucoperiosteum is made from the distobuccal region of the developing third molar anteriorally along the crest of the ridge to the distobuccal of the second molar and around the gingival margin of second and first molars. The mucoperiosteal flap is freed and elevated to allow adequate access. Bone overlying the third molar is removed with chisel or surgical bone bur sufficient to permit elevation and atraumatic removal of the tooth bud. Then it is left in its crypt to await transplant.

Preparing the Socket

The diseased first molar is then removed and the site prepared by removal of interseptal bone and enlargement of the socket with chisel or bur.

Transfer to Host Site

The transplant is now removed carefully from its crypt and transferred to the host site. It should be placed in approximately the same depth as it was found in its own crypt since the length of root growth will depend to some degree upon the distance it moves as it erupts into occlusion. The third molar socket is cleaned up by removing bone fragments, smoothing sharp edges, and removing dental follicle remnants. Then the mucoperiosteal flap is replaced and sutured.

Immobilization

Retention of the transplant is effected by means of silk sutures or wire crossing over the crown surface, extending from second molar to bicuspid. Surgical packs or acrylic splints are useful and often used, especially for lower posterior transplants.

Postoperative Care

The patient is instructed in general mouth care, diet and analgesics. Antibiotics are not routinely given, as was originally thought necessary. Postoperative x-rays are taken at completion of the operation and then at various monthly intervals as desired to follow growth and eruption.

Comments

It is quite common for the root canals and pulp chambers of transplanted teeth to become partially or completely filled in and obliterated by radiopaque tissue. Histologic studies of this tissue show that it is different from normal or secondary dentin. It is possible that the tissue within the pulp chamber is replaced by connective tissues in growth; thus the odontoblasts that lay down dentin are replaced by cells of inferior differentiation which deposit osteodentin and bone rather than the normal tubular dentin. Clinically this is of no significance as long as it occurs only within the

tooth, since the tooth seems to retain a healthy and functional state even without pulp chamber or root canals.

Conclusion

I would like to point out that autogenous transplantation of developing tooth buds is not only possible but is being done by many oral surgeons at the present time.

It is applicable mainly in teenagers.

Fully formed teeth cannot be transplanted with permanent success.

New Superstitions Still Popping Up

Old superstitions, unlike old soldiers, do not fade away. They are replaced by new superstitions and new misconceptions, says TODAY'S HEALTH GUIDE, the American Medical Association's manual of health information for the American family.

This is particularly true of superstitions and misconceptions about health. New scientific advances and discoveries breed a whole new crop of health superstitions.

Some of the new ones cataloged in the health book are—

Today, we have the mistaken idea that necessary and harmless chemicals used in processing foodstuffs may cause mysterious diseases like cancer. (They won't.)

We see people afraid to cook with aluminum utensils for fear of poisoning the food. (They will not.)

We observe people who refuse to wear glasses, and others who shun much-needed hearing aids. (Both are completely accepted by society today.)

People oppose fluoridation of public water supplies because the same chemical has also been used for poisoning rats, overlooking the fact that the whole difference lies in the matter of dosage. (Fluoridated water is completely safe.)

Many people blame climatic changes on the atomic bomb; past generations attributed such changes to artillery fire, to the use of radio and television. (The bomb has not changed climate.)

Countless mothers live in fear for their children's lives because a heart murmur had been reported. Although murmurs should be checked by a physician most heart murmurs are harmless.

There is still active opposition to the use of immunizing procedures, such as vaccination and immunization, because of superstitious dread of introducing a poison into the system. (The vaccines now in general use are safe.)

There is a modern cult of naturalism which holds that only "natural foods" are wholesome because foods grown with the aid of chemical fertilizers are inadequate. (This isn't true.)

Many harbor prejudices against canned or frozen or otherwise processed foods, and even advocate eating raw food exclusively. (Processing does not affect foods substantially, nor does proper cooking.)

There is one thing more exasperating than a wife who can cook and won't, and that's the wife who can't cook and will.—Robert Frost

Love is the triumph of imagination over intelligence.—H. L. Mencken

Cardiorespiratory Endurance

Before and After Regular Physical Activity*

JOHN NAUGHTON, M.D.**
Oklahoma City, Oklahoma

EACH YEAR MORE and more members of our affluent society avail themselves of an opportunity to participate sporadically in seasonal sports such as skiing. While many of the participants have been regularly active throughout their lives, most will be characterized by sedentary living patterns which predispose them to a greater risk of accident and of cardiovascular distress while performing sudden, strenuous physical exertion. Although proper physical conditioning may reduce the risk factor, there is little evidence available documenting the physical-fitness levels of middle-aged American men. This report is concerned with the physiologic observations recorded on a middle-aged man while he was sedentary and at periodic intervals after he initiated and maintained a program of regular physical activity. In addition, the methods used to assess his performance capacity are described.

Case Report

The subject was 48 years old when he volunteered for the study. After an appropriate history and physical examination he performed a standardized multistage treadmill test[1] in which he began walking at a speed of 3.4 mph on a one-per-cent grade. The speed remained constant while the slope of the treadmill bed was elevated one percent per minute. Blood pressure and pulse rate were measured by the auscultatory method during the last half of each minute, and a single lead electrocardiogram was recorded continuously by radiotelemetry.[2] Minute ventilation was measured during inspiration from a Tissot respirometer, and oxygen consumption was determined by the Douglas-Haldane method during every other minute. Walking was stopped when the pulse rate reached 180 beats per minute or earlier if he was dyspneic or had chest discomfort.

Following the initial evaluation he began a program of interval training during which he jogged one quarter of a mile in approximately 2½ minutes, walked an equal distance, and resumed jogging at the original pace for another quarter of a mile. He spent approximately 20 minutes a day performing this in-

Presented at the North West Medical Association Meeting, Sun Valley, February, 1968.

**Assistant Professor of Medicine and Physiology, University of Oklahoma Medical Center.

termittent program during the first six months. At that time he was re-evaluated on the treadmill in the same manner. As his physical condition improved he increased the distance jogged and decreased the duration of the recovery period. Eventually he negotiated two miles comfortably in approximately 18 minutes, subsequently increasing the distance gradually until he could jog comfortably four miles continuously in 32 to 36 minutes each day. It was estimated that his oxygen requirements for maintaining this pace were approximately 45 ml/kg, or about 12 to 13 times those of the resting metabolic state, and his estimated caloric expenditure during the four-mile sessions was between 400 and 500 kcal. He was re-evaluated on the treadmill at six-month intervals. For purposes of this report, the physiologic responses recorded during the first 12 minutes of each evaluation prior to and after six and 24 months of training will be compared.

Results

Aerobic Working Capacity*

During the initial examination pulse frequency reached 180 beats per minute on a 14-per-cent grade where the oxygen uptake was 34.6 ml/kg. This value approximated that recorded previously in a group of sedentary middle-aged men of comparable age.[3] During the next two years a gradual and steady increase in the aerobic working capacity was recorded and related to the quality and quantity of the activity program. After six months of regular physical activity, during which he performed interval training, the aerobic working capacity increased from 34.6 to 39.6 ml O_2/kg; after performing a steady-state jog of three to four miles at least three times a week the aerobic working capacity increased approximately an additional 7.0 ml O_2/kg. *Therefore, after two years of regular physical activity the peak aerobic working capacity increased from 34.6 to 46.2 ml O_2/kg, reflecting an overall increase in oxygen consumption of approximately 850 ml.*

Ventilation

The ventilatory volumes recorded while standing were slightly higher during each evaluation than those usually recorded in healthy men, and varied from 24.9 L/min during the initial study to 18.3 L/min when studied two years later. During each study a striking elevation of the minute ventilation during the initial four minutes of walking was recorded (Figure 1). This was followed by a decrease of the ventilatory requirement during the next three to six minutes of walking, and finally by a gradual increase during the latter part of each test. A volume of 90.9 L/min was recorded at an oxygen requirement of 31.3 ml/kg during the twelfth minute of the first test. This response indicated that the large ventilatory volumes recorded during the low levels of physical effort were induced by a combination of psychological and physiological adaptations to the treadmill test rather than solely by the metabolic demands. During subsequent evaluations the same relative pattern of over-ventilation during the early minutes of walking followed by a marked decrease in the ventilation at the higher oxygen requirements persisted. This was especially noticeable during the third evaluation when the minute ventilation recorded while walking on a 12-per-cent grade was 50.8 L/min compared to 56.0 L/min at an oxygen requirement of only 14.9 ml/kg. These findings indicated the importance of evaluating subjects objectively under a moderate degree of physical stress prior to making judgments about their ability to exercise satisfactorily. *The values recorded in this subject after two years of regular physical activity on the 10- and 12-per-cent grade indicated that a marked increase in ventilatory efficiency developed during the process of physical conditioning.*

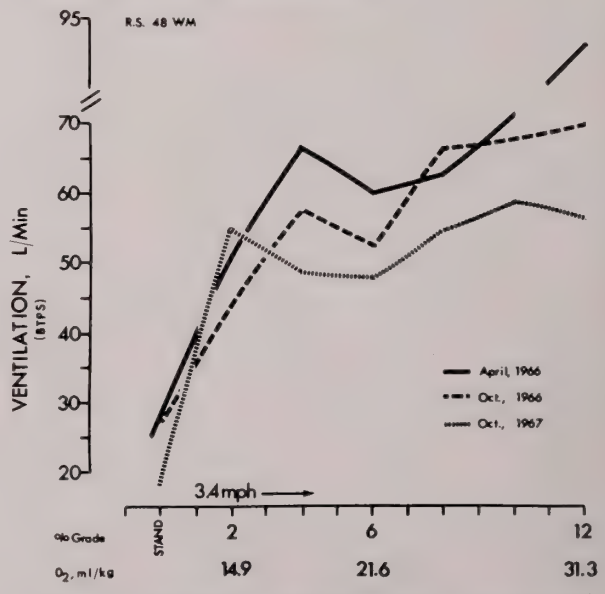

Fig. 1—Ventilatory responses before, during and after two years of regular physical activity.

*See Test Your Word Score Page 649.

Pulmonary Functions

Pulmonary functions were normal before initiating training (Table). These values remained essentially unchanged from one test to the next.

TABLE
Pulmonary Function Studies

	Total Vital Capacity (Liters)	1-Second Vital Capacity (Liters)	Maximum Voluntary Ventilation (L/min)
April, 1966	4.9	3.7	164
October, 1966	5.0	3.6	166
October, 1967	4.7	3.9	132

Blood Pressure

The resting blood pressure measurements were essentially normal upon entering the study. During the initial evaluation a characteristic, gradual increase of the systolic blood pressure accompanied each increased oxygen requirement (Figure 2). A peak value of 215 mm Hg was recorded during the twelfth minute of walking. At each subsequent evaluation substantially lower systolic blood pressure levels were recorded while resting and during exercise. Additional lowering of the systolic blood pressure occurred when the activity program became more strenuous. These changes in systolic blood pressure indicated that the systolic work of the heart and the oxygen cost of cardiac work had decreased at comparable levels of energy expenditure during the study.

During the initial study the diastolic blood pressure increased during walking approximately eight to ten mm Hg. However, two years later, although the resting diastolic blood pressure had not changed substantially, there was a decrease of this value during comparable levels of treadmill walking. *These latter changes indicated that a decreased peripheral vascular resistance had accompanied the training process* (Figure 3).

Pulse Rate

Pulse rates are generally regarded as the most objective means of evaluating an individual's state of physical fitness. Once again, as in the other physiologic measurements, significant reductions in the pulse rate during rest and throughout the treadmill test were recorded at each subsequent evaluation. The resting pulse rate decreased from 80 beats per minute initially to 56 beats per minute two years later; on a 12-percent grade these values decreased from 168 to 128 beats per minute. *These decreases indicated that a greater extraction of oxygen was accomplished per stroke beat after training and supported the concept that regular physical activity stimulates the development of cardiovascular efficiency* (Figure 4).

Discussion

The ability to cope with physical stress is a subject of import to every individual. Few people would argue that the safe performance

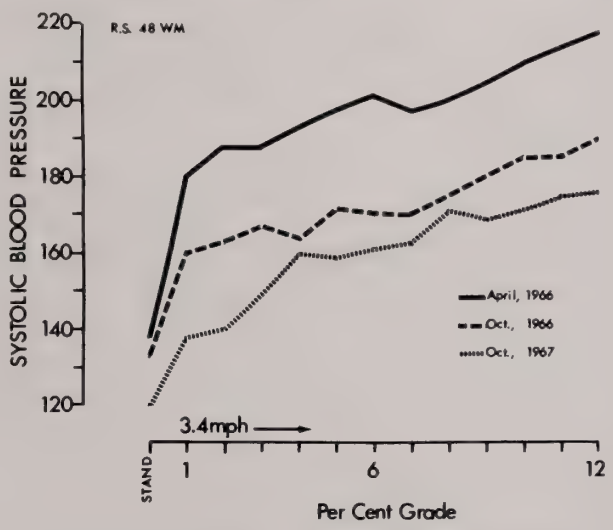

Fig. 2—Systolic blood pressure responses during treadmill walking.

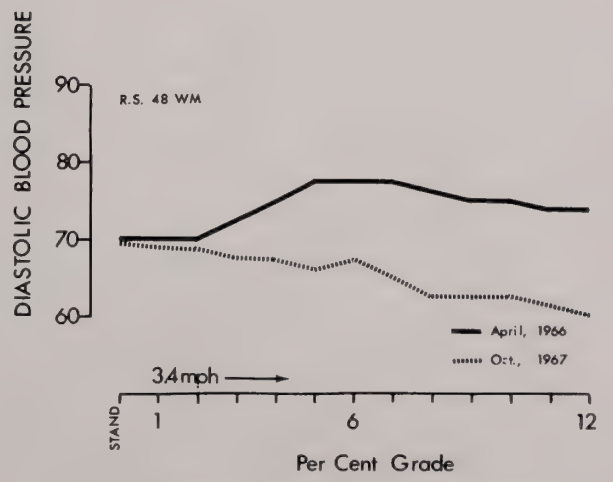

Fig. 3—Diastolic blood pressure responses.

of acceptable forms of physical recreation demands maintaining some level of physical fitness. However, measuring a subject's physical fitness readily and accurately poses a problem for many physicians. The test described here is an example of one of many graded exercise tests with which physicians can quantitate physical fitness. In addition to measuring the aerobic working capacity the physician can evaluate the quality and the quantity of the cardiorespiratory adjustment to the gradually increased workloads. While many physicians might find a treadmill an impractical instrument, a similar evaluation can be administered either with a stepper[3] or with a bicycle ergometer. It is obvious that for most clinical situations, a submaximal test in which the cardiorespiratory adjustments to gradually increased oxygen requirements are recorded simultaneously may provide enough information for the objective assessment of an individual's endurance capacity.

Although the relationship of physical fitness to health status is not known, it might be speculated that sports injuries are less frequent in better trained participants who do not fatigue readily. The patient depicted in this study was chosen because the responses recorded before and after regular physical activity approximated the mean values recorded in a larger group of men of comparable age. The findings illustrated many of the advantages of an "active physical examination." Although regarded as healthy by the usual clinical standards, the initial aerobic working capacity was average for men of his age, indicating that he could jog approximately 142 meters per minute or a mile in about ten minutes aerobically. Evidence of increased cardiorespiratory efficiency accompanied the activity program. When retested two years later the aerobic working capacity was 46.2 ml/kg, a capacity more than adequate for pursuing a distance of two miles in 15 minutes. It might be speculated that safe performance in competitive sports such as skiing was better assured after the training program than before. Similar alterations in functional adjustments to graded exercise were recorded in other healthy men who participated in a similar program.

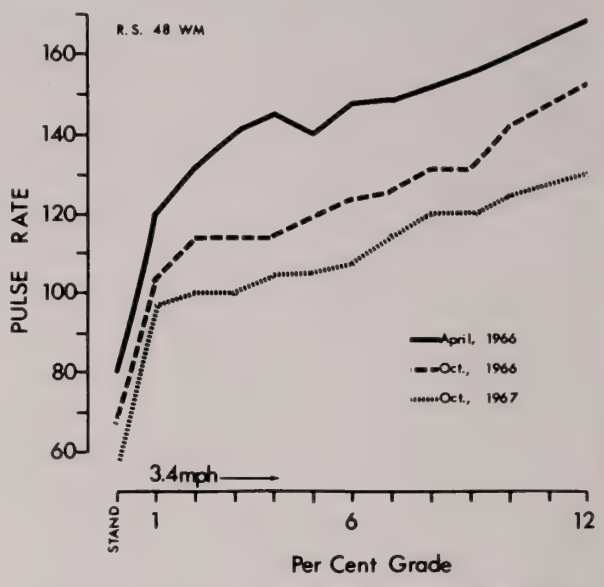

Fig. 4—A decreased pulse rate was recorded at rest and throughout walking at comparable levels of work as a result of the training program.

These findings also indicated that the trend toward a decreased oxygen capacity with age might either be delayed or even be reversed. For instance, several investigators[4,5,6] have reported a decreased physical working capacity in aging populations. Andersen and Hermansen[7] recorded peak oxygen consumption values of 34.0 to 36.0 in Scandinavian office and industrial workers between the ages of 50 to 54 years, and of 48.0 ml/kg in regular skiers of comparable age. The subject reported here demonstrated that it is possible to move from one category to the other with a program of regular physical activity.

Many types of endurance programs are conceivable and, as such, could be prescribed to meet each individual's specific requirements. Of the possible ways to increase endurance, jogging is probably preferable, since it can be performed almost anywhere with relative ease; requires very little expense and equipment; allows an individual the opportunity to pace himself; and at the same time taxes the cardiorespiratory system adequately. Pulse rates between 145 and 160 beats per minute are usually recorded in individuals during the type of program described here. Psychologically, many individuals react against jogging because they don't want to be the "lonely runner." These objections are usually handled if the

individual is properly instructed prior to initiating training. He should be informed that jogging the distance aerobically is more important than the speed, and that such programs are usually conducted regularly in YMCAs throughout the United States. Correlating the energy expenditure with the distance covered may also be of value. For instance, the person who performs to a 20-per-cent grade at 3.4 mph has an aerobic working capacity approximating 45 ml O_2/kg, a value roughly equivalent to the oxygen requirement of jogging one mile in eight minutes. The energy required to negotiate a mile would approximate 125 kcal. Therefore, a jog of three miles in 27 to 30 minutes would require an expenditure of 375 to 425 kcal.

Deconditioning is an additional indication for assessing an individual's aerobic working capacity. Since this often occurs as a result of an accident during physical activity, the objective assessment would be a measure of changes away from conditioning as well as toward conditioning.

Summary

The physical working capacity and cardiorespiratory adjustments to gradually increasing levels of physical exercise were measured in a 48-year-old healthy white man before he initiated an extended program of regular physical activity. He was retested at six-month intervals. His course was characterized by a subjective sensation of improved well-being and by objective evidence of improved cardiorespiratory efficiency, as well as by a substantial increase of his oxygen uptake from 34.6 to 46.2 ml/kg.

Revelation

The short skirts of today reveal the malnutrition of yesterday.—Don Herold

Surgical Detour

The Sklifosovsky Institute took in a new patient. He was nineteen years old and came from Sverdlovsk. Seven years previously the boy had swallowed some crude hydrochloric acid, which he mistook for water.

The esophagus stricture developed slowly but surely. To avert a total stricture doctors tried passing bougies, or special bulbous instruments, which were meant to dilate it. But that was of little help. The youth had to be fed through a stomach fistula. The doctors in Sverdlovsk tried to render more effective help and create a new esophagus. But the operation was unsuccessful.

At the Sklifosovsky Institute Professor Petrov examined the youth with utmost care. There were scars—marks of a surgeon's knife—on the patient's neck and chest.

A few days later the youth was put on the operating table. The surgeon opened up the abdominal cavity and drew out about 12 inches of the small intestine. He cut it at both ends with true surgical precision, detaching it from the bowels. Then he joined the two open ends of the bowels and thereby restored their continuity.

The excised piece of the small intestine had not lost all its connections with the bowels. Some blood vessels led to it from the mesentery. . . . If the vessels had been cut, the excised section of the intestine would be deprived of its blood supply and would soon perish.

The surgeon made a special tunnel-like passage under the skin of the chest. With the help of instruments specially designed at the Institute, he detached the skin from the underlying tissue all the way from the cut in the abdomen to the left collar-bone and the neck. This formed a subcutaneous tunnel. The excised intestine was carefully drawn into this tunnel. The tunnel was like a casing for it. One end of the intestine came to the surface on the neck, in line with the upper section of the esophagus.

The operation entered its second, no less important stage. The surgeon cut open the neck, bared the esophagus, and drew it out. He sutured the intestine into an opening in the wall of the esophagus above the stricture.

So much for the top end of the excised intestine. The bottom end, meanwhile, had been previously sewed into the stomach below the stricture. The excised section of the small intestine thus connected the topmost part of the esophagus with the stomach.

The operation on the youth was made in 1942. Before and after it, Professors Petrov, Arapov, Rozanov, and others of the Sklifosovsky Institute, performed hundreds of similar operations. A great many operations of this kind were since performed in other cities of the Soviet Union.*

Hyponatremia

Increased Antidiuretic Hormone and "Inappropriate" Thirst in a Patient with Bronchogenic Carcinoma*

WILLIAM E. SEGAR, M.D.**
Rochester, Minnesota

WARD W. MOORE, M.D.†
Indianapolis, Indiana

A DEPRESSION OF the serum sodium concentration below 135 mEq/L or of the serum osmolality below 270 mOs/kg. of water indicates excessive water for the amount of solute in the body. The serum sodium concentration is regulated by the thirst-neurohypophyseal-renal axis, and hyponatremia always suggests dysfunction of one or more components of this regulatory system.

An increased water intake causes hyponatremia only when associated with dysfunction of the neurohypophyseal-renal system. Normally an increased water intake inhibits antidiuretic hormone release, tubular reabsorption of water is decreased, and a dilute urine eliminates the excess water from the body. Following diuresis the expanded plasma volume and decreased osmolality return to normal and antidiuretic hormone release again permits the elaboration of an appropriately concentrated urine.

The role of thirst in this homeostatic system is frequently overlooked. The patient to be described was unable to elaborate a dilute urine, while large quantities of an antidiuretic hormone-like material (probably antidiuretic hormone) were produced by the cells of a bronchogenic carcinoma. However, a normal serum osmolality could have been maintained had the subject appropriately curtailed his fluid intake. That he did not do so suggests that, under these circumstances, his thirst was "inappropriate."

Report of A Case

The patient, a 62-year-old white male executive, was admitted to the Indiana University Medical Center on 8-29-65 because of fatigability and headaches. These complaints were attributed to a fall incurred five months previously that caused injury to his head and chest. Physical examination was normal on admission. An initial chest roentgenogram demon-

†Professor of Physiology, Indiana University School of Medicine.

strated a right lateral chest density suggesting a loculated pleural effusion or hematoma at a location which coincided with the site of previous injury.

Low Serum Sodium Concentration

The initial serum sodium concentration was 128 mEq/L and the serum chloride concentration, 88 mEq/L. These and additional laboratory studies are summarized in the Table. Various diagnostic procedures, including cerebral angiography, were compatible with the diagnosis of a right subdural hematoma, and on 9-13-65 a craniotomy was performed and a subdural hematoma removed. Microscopic examination of the resected tissue was not remarkable. However, hyponatremia persisted throughout the initial period of hospitalization. Because of the unresolved pleural density, chest roentgenograms were obtained repeatedly, and on 1-22-66 the existence of a right hilar mass became apparent.

High Antidiuretic Hormone

The patient was admitted to the hospital for the second time on 1-27-66. The serum sodium concentration was abnormally low and the urine contained an increased amount of sodium. The blood antidiuretic hormone concentration was found to be 12.5 μU/ml. The normal value for blood antidiuretic hormone in the seated adult human male is 1.6 ± 0.6 μU/ml. as assayed in our laboratory[1] using a modification of the method described by Yoshida et al.[2] Share[3] has shown that such methods extract and isolate a substance identical with antidiuretic hormone. An exploratory thoracotomy was performed on 2-4-66 which revealed an inoperable undifferentiated bronchogenic carcinoma. Tissue was obtained for bioassay of antidiuretic hormone as well as for routine histologic examination. On bioassay the tissue contained 525 microunits of antidiuretic hormone per mg. of tissue. The serum sodium concentration was 118 mEq/L on the second postoperative day although the patient had a daily fluid intake not exceeding 2,000 ml. The urinary output varied from 500 to 750 ml. per day. Serial weights of the patient are not available, and urinary sodium and total solute excretion were not measured during this period of hospitalization. Radiation therapy was begun on 2-10-66 and radiologic evidence of a tumor mass promptly disappeared. An antidiuretic hormone level on 3-14-66 was 1.7 μU/ml. of blood at a time when the serum sodium concentration and serum osmolality were normal. The patient was discharged on 3-18-66 and was followed in clinic.

On 8-30-66 his serum sodium and osmolal concentrations were again below normal, and a chest roentgenogram demonstrated a nodular lesion somewhat peripheral to the site of his previous radiation

therapy. He was readmitted to the hospital for chemotherapy. The blood antidiuretic hormone level on 8-30-66 had risen to 5.7 μU/ml., an abnormally elevated value. Following chemotherapy, radiologic and chemical evidence indicated that his disease process had again improved. The blood antidiuretic hormone level fell to 1.5 μU/ml. and the serum sodium concentration was normal. The patient was discharged from the hospital for the third time on 10-20-66, only to be re-admitted approximately three weeks later with the symptoms of cerebral metastases.

He died approximately one month later. Postmortem examination demonstrated diffuse intracerebral metastases of an anaplastic carcinoma with some residual evidence of undifferentiated bronchogenic carcinoma in the mediastinal lymph nodes.

Discussion

Schwartz and his associates[4] reported a syndrome of hyponatremia associated with bronchogenic carcinoma and attributed the hyponatremia to "inappropriate" antidiuretic hormone production. Many investigators have made similar observations, reviewed recently by Bartter and Schwartz[5]. Initially the source of the increased antidiuretic hormone was speculative. Recently however, Amatruda and his associates[6], as well as others[5], have demonstrated that such tumors may contain, and presumably release into the circulation, large quantities of antidiuretic hormone or an antidiuretic hormone-like substance. The present case, as well as the cases reported by Tisher[7] and by Utiger[8], demonstrate that an elevated blood antidiuretic hormone level and the associated hyponatremia can be corrected by treatment of the tumor. In our patient and the patient of Tisher, hyponatremia recurred upon recurrence of the tumor. It seems to be established that certain bronchogenic tumors do produce and release into the circulation antidiuretic hormone or an antidiuretic hormone-like material.

Naturesis

Renal salt loss, unrelated to either renal or adrenal disease, is a constant feature of this syndrome[5]. In the patient described above, large quantities of sodium and chloride were repeatedly present in the urine in the presence of coexistent hyponatremia. For example, on 8-30-66 his urine contained 199 mEq/L of sodium at a time when the serum sodium concentration was depressed. The pathophysiology of the increased sodium wasting which characterizes the syndrome of "inappropriate" antidiuretic hormone production has been the subject of numerous investigations.

Leaf and his co-workers[9] demonstrated that the administration of vasopressin and water to normal volunteers led to the development of hyponatremia followed by an increased renal sodium loss. During these experiments there was an increase in glomerular filtration rate and in renal sodium excretion, and the sodium balance became negative despite a diet containing an adequate salt content. When the fluid intake of the subject was restricted sufficiently to prevent a gain in weight, sodium excretion was not increased, indicating that antidiuretic hormone *per se* did not cause the naturesis. This suggests that the increased renal sodium loss was in some way related to an expansion of the extracellular volume.

There is good evidence that excessive salt wasting is indeed a consequence of overfilling of the extracellular compartment. At least two mechanisms may be operable. Bartter et al.[10] have shown that when the extracellular fluid volume is expanded by the administration of vasopressin and water, urinary aldosterone excretion is decreased. The naturesis can therefore be attributed, in part at least, to diminished aldosterone production. In these studies, as in the studies of Leaf et al.[9], the naturesis and decreased aldosterone excretion which occurred in response to the administration of pitressin and water could be reversed by water restriction. However, measurements of aldosterone secretion and excretion in patients with hyponatremia due to "inappropriate" antidiuretic hormone production have been within the usual range,[5,11] indicating that a decreased aldosterone secretion may not play a major role in the development of the naturesis.

A Hormone

Over-expansion of the extracellular compartment may induce sodium diuresis via a second mechanism. A hormone, as yet incompletely identified, that inhibits proximal tubular sodium reabsorption has recently been recognized. This hormone, the so-called "third factor," is apparently released from the cen-

tral nervous system upon expansion of the extracellular space and, through mechanisms unrelated to aldosterone suppression, causes naturesis[12]. An impressive body of experimental data has been accumulated that indicates this "third factor" to be responsible for the development of the naturesis seen during acute expansion of the extracellular compartment that occurs despite the administration of large amounts of a salt-retaining steroid[13,14,15]. This effect can be reversed by partial clamping of the vena cava[16]. These data suggest the existence of intravascular stretch receptors, located within the thorax, which are sensitive to changes in filling and are concerned with the release of the naturetic hormone. Heinemann and Laragh[17] have described a patient with the syndrome of inappropriate antidiuretic hormone release, in whom the naturesis was abolished by spontaneous occlusion of the vena cava. This observation would support the hypothesis that the naturetic hormone contributes importantly to the salt loss.

Expanded Extracellular Volume

Goldberg[18] has recently reviewed the problem of hyponatremia associated with increased antidiuretic hormone production and has concluded that the naturesis is a result, solely, of an expanded extracellular volume. He suggests that this response serves the useful function of preventing an even greater over-expansion of the extracellular compartment. Thus the relative constancy of extracellular volume is preserved at the expense of tonicity. Although we are unable to document over-expansion of the extracellular space in our patient, we have assumed it was present and contributed importantly to the development of the naturesis.

Curtailment of Fluid Intake

We have been intrigued by another aspect of this syndrome. Hyponatremia will not develop or, once developed, can be corrected by the curtailment of water intake. The voluntary ingestion of water in excess of total water loss represents, it seems to us, "inappropriate" thirst. The patient was highly intelligent, alert, and without evidence of cerebral dysfunction during the course of this study. Yet his voluntary water intake exceeded his excretory capacity. His thirst was not curtailed despite hyponatremia and, presumably, hypervolemia.

Physiology of Thirst

Relatively little is known about the factors regulating thirst in the human. It has been shown that hyperosmolality and/or hypovolemia cause the sensation of thirst[19]. In these circumstances the blood antidiuretic hormone levels are also elevated as both hypertonicity and hypovolemia result in antidiuretic hormone release[20]. Dryness of the mucous membranes or oral pharynx also produces a sensation of thirst irrespective of the individual's actual need for water[21]. However, each of these factors is associated with an increased thirst. The physiologic mechanisms, if any, that can curtail thirst to below normal levels are unknown.

In man fluid consumption is a habit, conditioned by psychological and social factors, and the excretion of water normally varies with variations in intake. When water losses are increased, thirst increases via the mechanisms noted above. When water losses are less than normal, as in the individual who can excrete only a hypertonic urine, thirst does not seem to decrease proportionately.

Three possible explanations occur. *First,* there are no effective homeostatic mechanisms present which can signal the organism to reduce fluid intake below normal. Such mechanisms may be of no biologic survival value since there are few circumstances where such a feed-back system would be beneficial. *Secondly,* homeostatic mechanisms of this type exist but are overwhelmed by habit, or psychologically-conditioned drinking. There is some experimental evidence that this might be the case. Fitzsimons[22] offered water *ad libitum* to rats whose total water requirement was met by intravenous infusion. The animals decreased, but did not cease their oral ingestion of water; and their total water intake was markedly increased over control values. Similarly, patients on intravenous fluid therapy will continue to drink if given the opportunity —a common cause of the hyponatremia that occurs following surgery. *Thirdly,* the inappropriate thirst of this patient and of others

with similar illnesses, as well as that of the volunteers in Leaf's study[9] who received pitressin and water *ad libitum,* may indicate that an elevated blood antidiuretic hormone concentration, per se, is a thirst-producing stimulus. In these circumstances the organism with hypo-osmolality and hypervolemia has the sensation of thirst, but accompanied by an elevated antidiuretic hormone level. The concentration of antidiuretic hormone in blood may play a significant role in the perception of the thirst stimulus. Which of these mechanisms is operant* in this patient is unknown. The role of antidiuretic hormone in thirst perception is, however, a promising area for subsequent investigation.

Summary

A 62-year-old male patient with bronchogenic carcinoma demonstrated hyponatremia, increased levels of blood antidiuretic hormone, and an "inappropriate" thirst. Analysis of biopsy material indicated the tumor contained 525μU of antidiuretic hormone/mg. of tissue. The blood antidiuretic hormone level and serum sodium concentrations returned to normal when a remission was produced by therapy. Upon relapse, hyponatremia and an elevated blood antidiuretic hormone recurred. Hyponatremia could not have developed, despite increased levels of blood antidiuretic hormone and a persistently hypertonic urine, had the patient appropriately curtailed his voluntary water intake. The possible causes of this "inappropriate" thirst may be due to a number of physiologic factors related to antidiuretic hormone.

Talk to a man about himself and he will listen for hours.—Benjamin Disraeli

Mr. President—Your Health*

James Monroe (1758-1831)

Healthwise the childhood and youth of our fifth President, James Monroe, was uneventful until early manhood when, during active military service at Trenton, New Jersey, his physical integrity was suddenly violated by a bullet which crashed into his shoulder and severed an artery. Thanks to immediate first-aid attention and subsequent meticulous care in a convalescent camp he survived and recovered; but the bullet remained ensconced in his shoulder for the rest of his life: a unique memorabile of his Revolutionary War service as a young lieutenant in the Third Virginia Regiment.

As a war veteran in Congress Monroe was often absent due to indisposition history fails to identify, but which may well have been of a gastrointestinal nature, a common enough aftermath of active army service. From this complaint he appears to have recovered later, with his health gradually improving until at age 71 he fell off his horse and sprained a wrist—after which, if not because of which—general physical decline set in until he died at age 73 of chronic bronchitis exacerbated by an acute cold.

His death, like John Adams', occurred on July Fourth, a melancholy but fitting memorial to the independence he had valiantly struggled to achieve for his country.

*With acknowledgment to and quotations from Karl C. Wold, M.D.: Mr. President—How Is Your Health? Bruce Pub., 1948.

Flu in Switzerland in 1918

I remember a day in the summer of 1918 when the epidemic of influenza was at its height. I was in the Swiss Army Medical Corps and had to report at headquarters. When I came to the small city of Porrentruy I found myself all of a sudden in a medieval atmosphere of terror and panic. The first sight was a huge stack of new coffins at the railroad station. In the city the population was in a state of tension and extreme nervousness. Many were weeping in the streets. Some had relatives dying at home, others feared for their own lives. The wildest rumors were circulating and found all-too-credulous ears. Alcoholic drinks were supposed to protect against the disease and people were seen drunk in the streets in the early morning. According to another rumor the workers of the local tobacco factory had been spared and I saw women with huge cigars who had never smoked before. . . . Physicians were scarce; they were sick themselves or in the army, and since I was in the uniform of an army physician I was dragged into dozens of houses and was almost kidnaped, so that I could hardly fulfill my task. People clung to the physicians and expected miracles from them, not realizing how helpless we were. A few months later, on an epidemiological survey I came to an Alpine hut, high up in the mountains, and found all the inhabitants dead. It was a horrible sight, the bodies livid and in the early stages of decomposition. Terrified, my guides muttered, "The Black Death"—which it was clinically if not etiologically.*

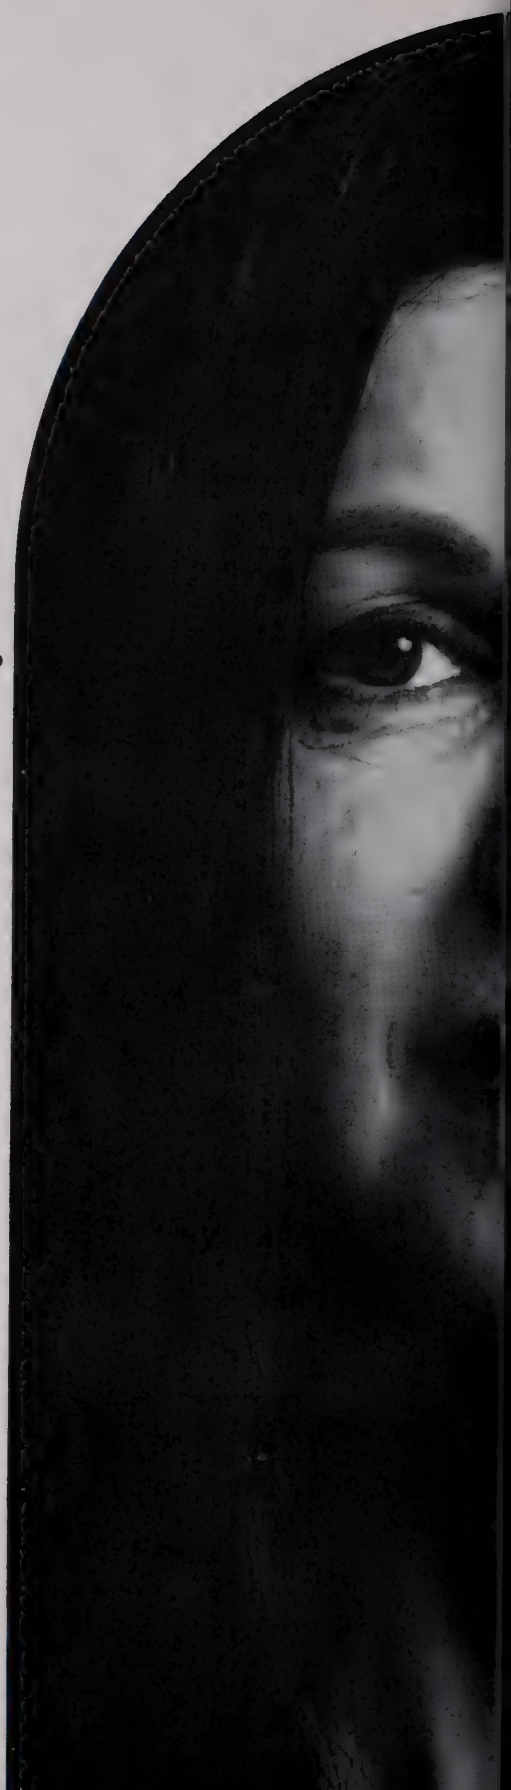
Forgiveness

God may forgive you your sins, but your nervous system won't.—Alfred Korzybski

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.



Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

Vistaril®
HYDROXYZINE PAMOATE

an antianxiety agent that serves a human need...

"The danger involved in prescribing dependency producing medication for relief of anxiety lies in the fact that we do not know in advance the dependency proneness of the individual."[1]

A woman who is undergoing the emotional stresses of the menopause may, for the first time, need an antianxiety agent. But she may also be susceptible to drug abuse.

Vistaril can fulfill the need for tranquilization without creating a new need—dependency.

Vistaril calms anxiety and agitation quickly—usually begins to work in 15-30 minutes. And, in more than ten years of clinical use, after more than a billion doses to date, there have been no reported instances of dependency on hydroxyzine.

When the need for antianxiety medication is reduced or no longer exists, Vistaril dosage may be lowered or discontinued without ill effects.

Recommended starting dose, anxious menopausal patient, 50 mg. t.i.d.

With Vistaril, it is as easy to stop therapy as it is to start.

without
creating
a new one.

Contraindications: Hypersensitivity to hydroxyzine. The parenteral solution, for intramuscular or intravenous use, *must not* be injected subcutaneously or intra-arterially.

Hydroxyzine, when administered to the pregnant mouse, rat, and rabbit induced fetal abnormalities in the rat at doses substantially above the human therapeutic range. Clinical data in human beings are inadequate. Until adequate data are available to establish safety in early pregnancy, hydroxyzine is contraindicated during this period.

Precautions: Hydroxyzine may potentiate the action of central nervous system depressants such as narcotics and barbiturates. In conjunctive use, dosage for these drugs should be decreased as much as 50%. Because drowsiness may occur, patients should be cautioned against driving a car or operating dangerous machinery. The usual precautions for intramuscular injection should be followed; soft-tissue reactions have rarely been reported when proper technique has been used. Hydroxyzine parenteral solution for intramuscular use should be injected well within the body of a relatively large muscle. In adults, the preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus), or the mid-lateral thigh. In children, preferably the mid-lateral muscle of the thigh. In infants and small children the upper outer quadrant of the gluteal region should only be used when necessary, as in burn patients, in order to minimize the possibility of damage to the sciatic nerve. The deltoid area should be used only if well developed, such as in certain adults and older children, and only with caution to avoid radial nerve injury. Injections should not be made in the lower and middle thirds of the upper arm. Aspiration should be done to help avoid intravascular injection. On reported intravenous injection a few instances of digital gangrene have occurred distal to the injection site, considered to be due to inadvertent intra-arterial injection or possibly periarterial extravasation. Therefore, particular caution (aspiration and site injection) should be observed to insure injection only into intact veins; avoid either intra-arterial injection or extravasation. Intravenous administration should be accomplished slowly, no faster than 25 mg. per minute, and not to exceed 100 mg. in any single dose. In order to avoid possible adverse effects it is recommended that hydroxyzine parenteral solution be diluted to at least 50 cc. with sterile normal saline and administered over a period of four minutes or more, preferably into the tubing of a running intravenous infusion.

The intravenous administration of this drug is not recommended for children under 12 years of age.

Adverse Reactions: Drowsiness may occur; if so, it is usually transitory and may disappear in a few days of continued therapy or upon dosage reduction. Dryness of the mouth may occur with higher doses. Involuntary motor activity, including rare instances of tremor and convulsions, has been reported, usually with higher than recommended dosage.

When this product is given intravenously undiluted, minimal amounts of intravascular hemolysis occur at the site of injection. Giving the maximum recommended intravenous dose (100 mg.) to adults results in immediate transient hemolysis with the liberation of a total of 2-3 grams of hemoglobin, which, in some individuals, can cause small amounts of hemoglobinuria. This compares with the normal red cell destruction from which approximately 8 Gm. of hemoglobin are liberated every 24 hours. If the hydroxyzine is diluted with 50 cc. of normal saline and given during a period of four minutes or more, this phenomenon does not occur.

Supply: Vistaril (hydroxyzine pamoate) Capsules: Equivalent to 25 mg., 50 mg., 100 mg. hydroxyzine HCl. Vistaril (hydroxyzine pamoate) Oral Suspension: Equivalent to 25 mg. hydroxyzine HCl per 5 cc. teaspoonful. Vistaril (hydroxyzine HCl) Parenteral Solution: 25 mg./cc.—10 cc. vial and 50 mg./cc.—2 cc. and 10 cc. vial; Isoject,® 25 and 50 mg. per cc., 1 cc. per unit.

More detailed professional information available on request.

burning
itching
discharge
of trichomonal vaginitis...

Flagyl®

tablets/inserts

brand of

metronidazole

brings
• clinical cures
• microscopic cures
• culture cures

For the most widespread form of vaginitis the most widely successful therapeutic agent, Flagyl, is clearly indicated.

In trichomonal vaginitis, most physicians have reported a cure-rate of 95 per cent or more with Flagyl when infected male partners are treated concurrently and when treatment is repeated for occasional refractory infections in women.

Among the few patients who do not respond to Flagyl are those who may not have taken the prescribed dosage and those who may have been reinfected.

This high rate of cure obtained with Flagyl is unparalleled. Only systemically active Flagyl reaches the hidden reservoirs of reinfection in male and female genitourinary tracts.

Indications: Flagyl is indicated only in the treatment of trichomoniasis in both the male and female.

Contraindications: Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precaution: Complete blood cell counts should be made before, during and after therapy, especially if a second course is necessary.

Side effects: Infrequent and minor side effects include nausea, metallic taste and furry tongue. Gastrointestinal disturbances, flushing and headache sometimes occur, especially with concomitant ingestion of alcohol. The taste of alcoholic beverages may be altered. Other effects, all reported in an incidence of less than 1 per cent, are diarrhea, dizziness, vaginal dryness and burning, dry mouth, rash, urticaria, gastritis, drowsiness, insomnia, pruritus, sore tongue, darkened urine, anorexia, vomiting, epigastric distress, dysuria, depression, vertigo, incoordination, ataxia, abdominal cramping, constipation, stomatitis, numbness or paresthesia of an extremity, joint pains, confusion, irritability, weakness, cystitis, pelvic pressure, dyspareunia, fever, polyuria, incontinence, decreased libido, nasal congestion, proctitis and pyuria. Elimination of trichomonads may aggravate candidiasis.

Dosage and Administration: In women: one 250-mg. oral tablet three times daily for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When used, one vaginal insert should be placed high in the vaginal vault each day for ten days; concurrently two oral tablets should be taken daily.

In men: When trichomonads are demonstrated, one 250-mg. oral tablet twice daily for ten days in conjunction with treatment of his female partner.

Dosage Forms: Oral tablets—250 mg.
Vaginal inserts—500 mg.

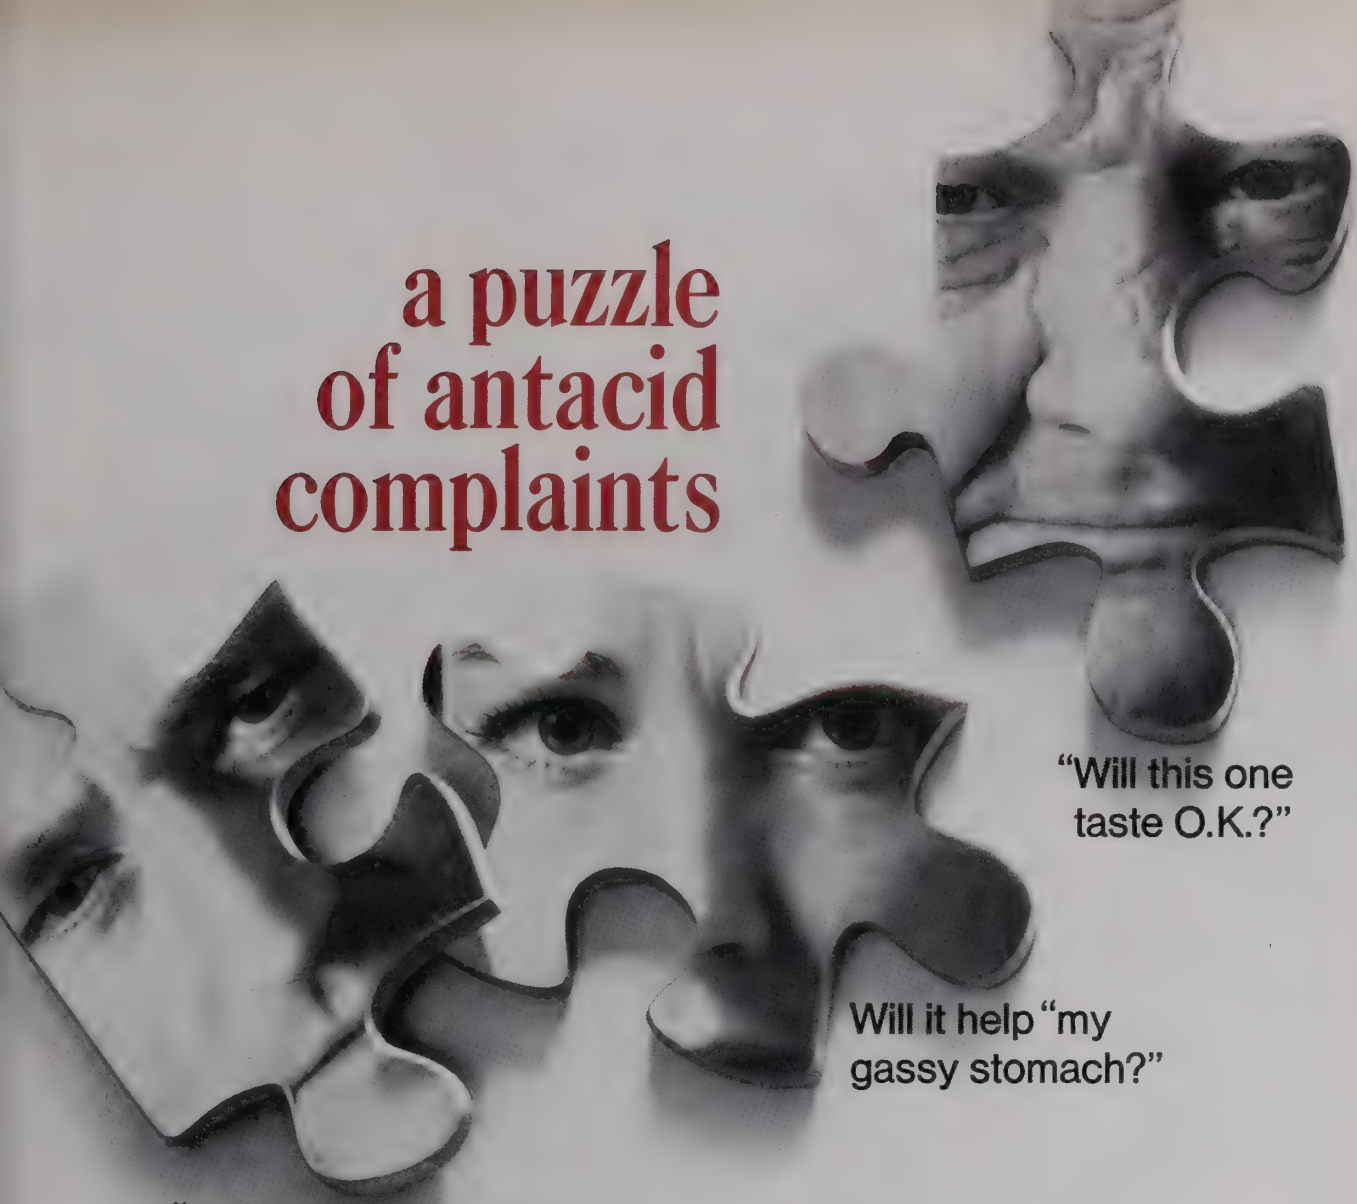
CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg., phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).



One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

with the two most widely prescribed antacids: aluminum and magnesium hydroxides.

Concomitant relief of G.I. gas distress—
with the proven[1] defoaming action of simethicone.

Prolonged acceptance confirmed—
in 87.5% of 104 patients after a total of 20,459 documented days of therapy.[2]

Composition: Each Mylanta chewable tablet or teaspoonful (5 ml.) contains: magnesium hydroxide, 200 mg.; aluminum hydroxide, dried gel, 200 mg.; simethicone, 20 mg. Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth) or one or two teaspoonfuls to be taken between meals and at bedtime.

Stuart Division/Pasadena, Calif.
ATLAS CHEMICAL INDUSTRIES, INC.

When the agitated geriatric disrupts the home...

His daughter can't please him. There is "just no living with him."

His disturbances at the table make every meal a nightmare.

His teen-age granddaughter won't invite friends home because of his outbursts.

His slovenly room and habits create more tension.

In moderate to severe anxiety...

- Mellaril helps control the most frequent symptoms: marked tension, agitation, apprehension, restlessness, hypermotility
- Mellaril often alleviates anxiety-induced somatic complaints
- Mellaril frequently helps strengthen emotional resources
- Mellaril helps the patient maintain realistic contact with environment, closer harmony with family

Contraindications: Severely depressed or comatose states from any cause, and in association with or following MAO inhibitors; severe hypertensive or hypotensive heart disease.

Precautions: Hypersensitivity reactions (e.g., leukopenia, agranulocytosis) and convulsive seizures are infrequent. Pigmentary retinopathy has been observed where doses in excess of those recommended were used for long periods of time. May potentiate central nervous system depressants, atropine, and phosphorus insecticides. Where complete mental alertness is required, administer the drug cautiously and increase dosage gradually. In addition, orthostatic hypotension (especially in female patients) has been observed. Epinephrine should be avoided in treatment of drug-induced hypotension.

Side Effects: Pseudoparkinsonism and other extrapyramidal disorders are infrequent; drowsiness, especially in high doses early in treatment, may occur; nocturnal confusion, dryness of the mouth, nasal stuffiness, headache, peripheral edema, lactation, galactorrhea, and inhibition of ejaculation are noted on occasion; photosensitivity and other allergic skin reactions may occur but are extremely rare.

for moderate to severe anxiety

Mellaril®

(thioridazine)

25 mg. t.i.d.

Editorials

Artificial Heart

In the March issue of Minnesota Medicine* Dr. Blackshear, in an editorial, commented on the international effort to develop an artificial heart and on the approach our group has selected in the development of such a heart. He also made an analysis of the results we have obtained, and his warm endorsements regarding our pump and approach are both gratifying and particularly significant since these views come from a member of a team representing what is commonly recognized to be the heart surgery capital of the world.

In our opinion, the features which distinguish our constrained force-vortex pump from the Telsa pump are responsible in large measure for the capability of our pump to handle the blood atraumatically. Dr. Blackshear made reference to the significant distinguishing feature when he noted that we employed a viscous flow impeller, and then went on to say that the impeller, being remote from the cells, should minimize damage to cells. This is one of the major features that prompted us to select this type of impeller, which we prefer to speak of as a rotator. Using this type of rotator the pressure head and flow are developed by the constrained force-vortex principle in which, after the initial acceleration is imparted by the rotator to the fluid, the fluid itself serves as the prime mover. In contradistinction, the Tesla pump operates as a shear-force pump in which pressure head and flow are developed through the continued action of the impeller as the prime mover due to its closely spaced plates. Although siliconizing the surfaces of our unit helped to keep hemolysis low as pointed out by Blackshear we feel that the engineering features of our pump are of prime importance in avoiding hemolysis.

Approaching the development of an artificial heart by the use of a pump which produces a nonpulsatile flow represents a deviation from the more stereotyped, conventional approaches producing pulsatile flow. The physiological necessity of pulsatile flow has yet to be established.

It will also be important to develop new plastics having stable non-traumatic surfaces. Attention to these and other such basic considerations must comprise an essential part of the program to ultimately develop a successful artificial heart.

The research carried out by Dr. Blackshear's group represents, in our opinion, some of the most scholarly work done in the artificial heart field. Their investigations have been directed at seeking answers to basic and fundamental problems that must be solved in establishing a logically developed mechanical heart program, and their approach should serve as a model for other groups working in this field. It is characterized by a methodical compilation of basic data serving as a solid base from which their overall program may be developed. Great-

Weariness "without cause"

Psychic tension with depressive symptomatology?

"For weeks I've done practically nothing and I'm always tired. I wake up tired and I go to bed tired. It's really absurd."

When the patient complains of fatigue, and you can find no organic cause, you recognize that it may serve her as a means of avoiding responsibilities or facing an emotional problem. It is, in effect, a psychological retreat behind a somatic cover of continuous fatigue —one of the many depressive symptoms often associated with psychic tension.

She needs counsel and reassurance, and perhaps a tranquilizer to attenuate excessive tension and help restore the capacity to cope. As an aid to successful management, consider the value of Valium® (diazepam). As psychic tension is eased by Valium therapy, secondary depressive symptoms too may subside. The patient feels more capable, therefore more hopeful; better able to handle situations of intense stress.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in: skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders; athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindications: Known hypersensitivity to drug; children under 6 months of age; acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in treatment of psychotic patients, and should not be employed in lieu of appropriate treatment. As with most CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increase in dosage of standard anticonvulsant medication; abrupt withdrawal in such cases may also be associated with temporary increase in frequency and/or severity of seizures. Advise patients against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance. Keep addiction-prone individuals (such as drug addicts or alcoholics) under careful surveillance because of their predisposition to habituation and dependence. Use of any drug in pregnancy, lactation or in women of childbearing age requires that potential benefit be weighed against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, carefully consider individual pharmacologic effects —particularly with known compounds which may potentiate action of Valium, such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants. Employ usual precautions in the severely depressed or in those with latent depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation (initially 2 to 2½ mg once or twice daily, increasing gradually as needed or tolerated).

Adverse Reactions: Side effects most commonly reported: drowsiness, fatigue and ataxia. Infrequently encountered: confusion, constipation, depression, diplopia, dysarthria, headache, hypotension, incontinence, jaundice, changes in libido, nausea, changes in salivation, skin rash, slurred speech, tremor, urinary retention, vertigo and blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances and stimulation have been reported; should these occur, use of the drug should be discontinued. Because of isolated reports of neutropenia and jaundice, periodic blood counts and liver function tests are advisable during long-term therapy. Minor changes in EEG patterns (low-voltage fast activity) observed during and after therapy and are of no known significance.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See **Precautions.**) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg, and 10 mg; bottles of 50, 100 and 500.

Amputations in Peripheral Vascular Disease

THE SOCIOECONOMIC aspects of peripheral vascular disease* continue to assume increasing proportions in our burgeoning population with greater longevity. Lengthy hospitalizations, frequent complications, demanding nursing care, and poor prognoses in this group of patients in a time of rising hospital costs and tax-supported medical care constitute increasing problems.

Early adequate explanation of the importance of foot hygiene in the diabetic is an oft neglected area of preventive medicine. The proper trimming of toenails and calluses, the protection of corns and bunions, and the early recognition of neurotrophic** disturbances should be promoted. Careful daily bathing, daily changing of socks, and foot inspection are equally valuable for patients suffering from occlusive vascular disease with or without diabetes. In selected patients, sympathectomy may prolong the useful function of the lower extremities. Although arterial bypass procedures have not borne the fruit of promise we had hoped for a decade ago, the indication for their use has been well defined and occasionally is extremely helpful.

The immediate fitting of prostheses has increased the flexibility with which we may deal with amputees, but certain limitations are encountered. The firm confines of the rigid socket on recently wounded tissue whose vascular sustenance is already impaired may lead to occasional wound breakdowns. Open-flap amputations with delayed primary closure, particularly in the face of septic gangrene of the foot, still have a most useful place in amputation surgery.

If we are to deal intelligently and humanely with the patient afflicted by occlusive vascular disease, affording him the best opportunity to find his level of rehabilitation, and if we are to assume our responsibilities in keeping the cost of medical care at an optimal level, a thorough knowledge of the factors affecting amputations is desirable. The comprehensive guide submitted by Dr. Kane offers a succinct summary of our present knowledge.

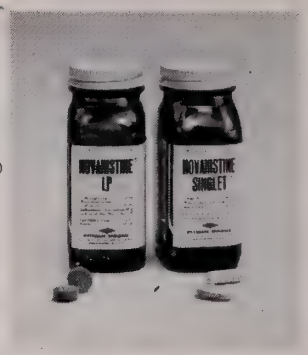
Learn to accept in silence the minor aggravations, cultivate the gift of taciturnity, and consume your own smoke with an extra draft of hard work, so that those about you may not be annoyed with the dust and soot of your complaints.



—William Osler

Silence is one of the hardest arguments to refute.—Josh Billings

Some U.R.I. patients are more miserable than others.

That's why we make Novahistine® tablets in two different formulations.

And let you control the dosage.

Each Novahistine LP tablet contains phenylephrine hydrochloride, 25 mg.; and chlorpheniramine maleate, 4 mg.
Each Novahistine Singlet tablet contains phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; and acetaminophen, 500 mg.

With Novahistine LP tablets and Novahistine Singlet™ tablets you have the range and flexibility of decongestant dosage that lets you prescribe for the needs of the individual patient.
Novahistine LP tablets are most useful for relief of nasal congestion in patients without pain or fever. Novahistine Singlet tablets, which provide analgesic-antipyretic effect, as well as decongestant action, are indicated for upper respiratory infections accompanied by pain, aches and fever.
Whether you prescribe Novahistine LP or Novahistine Singlet, a total daily dose of 3 or 4 tablets will usually provide effective, continuous relief.
Use cautiously in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

"Nothing else I've tried seems to work, so I decided to give you a crack at it."

Radical Pancreatoduodenectomy

PANCREATODUODENECTOMY is the only treatment that offers any possibility of cure or prolonged survival in relative comfort for those afflicted with cancer of the pancreas, distal common duct, or papilla of Vater.

The operation is an extensive procedure since it involves multiple organs and intricate dissection with multiple suture lines in reconstruction. Mortality and morbidity from the procedure have steadily declined since the operative procedure was conceived over 30 years ago, so that now many medical centers are able to report mortality rates approaching 10 to 15% in the later years of their total experience.

Carcinoma of the pancreas continues to be difficult to diagnose in its early stages. Recent innovations such as celiac angiography and radioactive selenium scan have thus far not been helpful in detecting early lesions. Even at the time of laparotomy, difficulty may be encountered in arriving at a diagnosis, and the surgeon must make a decision based on indirect evidences, the accuracy of which will be influenced largely by his experience in treating pancreatic lesions. Understandably, some surgical departments and hospital staff may insist on a tissue diagnosis before a radical pancreatoduodenectomy is undertaken; but this viewpoint seems to be disappearing, partly because mortality from the procedure has declined, but more especially because multiple negative biopsies do not give absolute assurance that the lesion is benign. Usually this is the case in patients with small lesions having the best chance for cure. This view has been reiterated by so many with extended experiences in pancreatic surgery that it has become common knowledge among our medical colleagues as well as among surgeons at large.

Another area of deliberation is whether a patient with pancreatic carcinoma should have the radical resection or only a shunting procedure? Emphasis has recently been placed on the desirability of taking extra measures to determine if resection is indicated, based upon inspection and the taking of biopsies of various areas outside of the pancreas where early spread is known to occur. Such examination is logical, since extensive procedure should not be undertaken when possibility of cure is remote. On the other hand, something can be said for performing a pancreatoduodenectomy if technically feasible, even though some tumor may be left behind; since large-series reviews show that prolonged and real palliation occurs more frequently in patients who have had resection rather than a bypass procedure.

In reporting results of pancreatoduodenectomy, it is important to differentiate carcinoma of the papilla of Vater from carcinoma of the pancreas since it is well known that the two behave differently. Reports on five-year survivals on the combined groups presents too favorable a view for carcinoma of the pancreas and too unfavorable a view for carcinoma of the papilla of Vater.

The report of L'Esperance* is notable in several aspects. He has shown that radical pancreatoduodenectomy can be done in a relatively small hospital if it is well equipped and staffed. He also has shown that advanced age need not be a deterrent to the extensive procedure and that he has apparently achieved a cure from ductal carcinoma of the pancreas. He further emphasizes that patients should be given every opportunity for cure; and if, at operation, a pancreatic lesion is found but cannot be dealt with for any of a number of reasons other than for advanced state of the disease, surgical assistance should be sought or the patient transferred to a hospital where definitive operation can be done.

Blame It On Eve

Labor pains are women's penalty for Eve selling apples without a license.
—M. A. Perlstein

When it's time for Thorazine® brand of chlorpromazine

...can you depend on less?

For profound calming effect in moderate to severe mental and emotional disturbances of everyday practice.

Before prescribing, see complete information, including adverse effects reported with phenothiazines and symptoms and treatment of overdosage, in SK&F literature or *PDR*. The following is a brief precautionary statement.

Contraindications: Comatose states or the presence of large amounts of C.N.S. depressants.

Precautions: Potentiation of C.N.S. depressants may occur (reduce dosage of such agents when used concomitantly). Use with caution in patients with chronic respiratory disorders. Antiemetic effect may mask overdosage of toxic drugs or obscure other conditions. Administer in pregnancy only when necessary. Because of possible drowsiness use cautiously and warn patients who operate vehicles or machinery.

Adverse Reactions: Drowsiness; dry mouth; nasal congestion; constipation; amenorrhea; miosis; mild fever; weight gain; hypotensive effects, sometimes severe with I.M. administration; epinephrine effects may be reversed; dermatological reactions; parkinsonism-like symptoms on high dosages (in rare instances, may persist); lactation and moderate breast engorgement (in females on high dosages); and less frequently, cholestatic jaundice (use cautiously in patients with liver disease). Adverse reactions occurring rarely, include: mydriasis; agranulocytosis; skin pigmentation; epithelial keratopathy; lenticular and corneal deposits (after prolonged substantial doses).

Available: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg.; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg.; Injection, 25 mg./cc.; Syrup, 10 mg./5 cc.; Suppositories, 25 mg. and 100 mg.

Diverticulitis

Loffer and Bergquist* call attention to the difficulties encountered in differentiating pelvic masses and tenderness due to diseases of the reproductive organs themselves from those caused by diverticulitis of the sigmoid colon. The case which they report also brings out the possibility that two separate diseases can coexist—in this instance, carcinoma of the endometrium and abscess from a diverticulum of the lower descending colon. While this latter situation is uncommon, the possibility of its occurrence must obviously be borne in mind. One need not go beyond one's own practice to note how frequently it becomes necessary to call in a gynecologic consultant to help in such situations. When fistulae develop, i.e., sigmoido-vesical, sigmoido-vaginal and sigmoido-uterine, the differentiation is greatly simplified. Carcinoma of any of the pelvic organs rarely develops fistulae except in far advanced stages. But simple, tender masses in the adnexae, especially on the left, can frequently cause difficulty.

Diverticulitis of the colon appears to be on the increase. Whether this is due to improved diagnosis or to an increased incidence is difficult to determine. Most authors seem to believe that the apparent increase in frequency has been real. It becomes necessary, then, for us to keep this possibility in mind whenever a patient presents with left lower abdominal pain and change in bowel habits, especially if fever, a sausage-shaped mass in the left lower quadrant and rebound tenderness exist. Symptoms and signs may be much less precise, especially in older age groups where this disease predominates.

Complications which may develop include those mentioned above in addition to free perforation with peritonitis, enterocolic and external fistulae, obstruction and hemorrhage. All but the last mentioned require surgical intervention.

A rather abundant literature concerning medical vs. surgical treatment of acute and recurrent diverticulitis has accumulated, predominantly in the surgical literature. An excellent review of this subject may be found in the British Medical Journal.** These authors concluded, "The course appears more benign than is often suggested, with a strong tendency to natural regression. A few patients experience prolonged and severe morbidity and will merit resection. The study suggests that extension of the scope of resection to include frequent emergency or three-stage resection for patients with acute diverticulitis is not justified."

The decision as to whether surgery should be resorted to after two, three or more recurrences cannot be arrived at by statistical means. It will require the mature judgment of the physician. He will be helped by such considerations as the frequency and severity of attacks, the degree of recovery between attacks, the persistence of a tender mass in the left lower quadrant, persistent fever and leukocytosis, interference with normal bowel function and the like. It is generally agreed that when surgery becomes necessary it should be carried out during a quiescent phase, preferably about six weeks after intensive treatment of an acute attack with bed rest, low-residue diet, non-absorbable sulfonamides and/or appropriate antibiotics and possibly hot abdominal compresses. At that stage a simple resection of the involved segment, making certain that all of the involved colon is included, with end-to-end anastomosis is usually well tolerated.

The subject of bowel hemorrhage from diverticulitis has been well reviewed by Riggs and Ewing.† They believe that *massive* hemorrhage from diverticulitis has been well documented, and that management of this complication should be conservative. However, their review of cases of *mild* rectal bleeding is much more disturbing. In 261 cases of diverticulitis with mild rectal bleeding 50% had associated disease including benign polyp, malignant polyp and carcinoma, with 29% having malignant disease. Careful consideration must, therefore, be given this group and many will require surgery.

Laryngectomy

From the time Billroth reported the first laryngectomy in 1873 until Chevalier Jackson outlined indications for the operation in 1904, only a few such cases were reported. In the early years of this century intrinsic laryngeal cancer was treated by thyrotomy without node dissection. Laryngectomy was reserved for advanced laryngeal cancer with removal of cervical lymph nodes, "whether they were felt to be enlarged or not," as advocated by De Santi in 1904.

In subsequent years, with the rise of radium and radiation therapy, extrinsic, i.e., non-cordal, cancer of the larynx came to be considered an inoperable lesion and was widely treated by the newer method. In the last two decades there has been a return to the precepts of the earlier period. Doctors Ogura and Bello in 1955 demonstrated that poorer results in the surgical treatment of non-cordal lesions were due to the presence of microscopic tumor deposits in clinically impalpable cervical lymph nodes. Adoption of routine neck dissection en bloc with laryngectomy has greatly improved cure rates for aryepiglottic fold and pyriform sinus cancers.

Preservation of the voice in the surgical treatment of some supraglottic tumors became feasible as a result of detailed studies of the embryology (Most) and lymphatic drainage (Rouvière) of the larynx. Lymphatic pathways from the supraglottic larynx which develops from the primitive pharynx were found to be independent of those of the vocal cords and subglottic larynx—derived from the superior extremity of the tracheal tube.

Based on these considerations and on the successful two-stage partial horizontal laryngectomy reported by Alonso, Ogura devised a one-stage supraglottic subtotal laryngectomy for epiglottic cancer and reported on its use in 1958. This procedure which preserves both the voice and the swallowing function is a landmark in the surgical treatment of laryngeal cancer. Conservation surgery has since been extended to selected tumors of the pyriform fossa and the posterior pharyngeal wall so that Ogura now feels that as many as half the cases of supraglottic and laryngopharyngeal cancer can be treated with preservation of voice and swallowing.

In the June issue Doctors Ogura and Barnhill* outline their remarkable experience with conservation operations for cancer of the larynx and laryngopharynx. Of particular interest is their success in the surgical treatment of the notorious superior hypopharyngeal tumors with 13 of 32 patients (41%) alive and well at the end of two years, and their restrained optimism in the use of preoperative irradiation for relatively advanced laryngopharyngeal tumors. This last experience concurs with preliminary reports of similar series from Mount Sinai Hospital, New York (Goldman et al.) and Presbyterian-St. Luke's Hospital, Chicago (Hendrickson).

Knowledge of the detailed and precise limits of the tumor in relation to its anatomic site within the larynx is now prerequisite for appropriate surgical attack, and contrast laryngography and cinematography are employed as well as endoscopic methods. A standard classification of laryngeal cancer, such as the tumor node metastasis (TNM) method of staging reported by the American Joint Committee on Cancer Staging and End Result Reporting in 1962, has long been needed for the appraisal of differing therapeutic regimens. In spite of some imperfections pointed out by Norris, this development comes at a time to complement conservation surgery in lending some sophistication to the modern treatment of laryngeal cancer.

DOW

A Disease Entity?

THE CASE reported by Dr. Mack* in this issue resembles, clinically and pathologically, those cases reported by Reye and collaborators.[1] Unfortunately, Dr. Mack's report does not include any data on the blood or cerebrospinal fluid sugar. The blood urea was not elevated as it had been in nine of the 12 patients reported by Reye and collaborators. The serum carbon dioxide content was normal, whereas it was low in many patients whose cases were reported recently. One could have suspected that this patient had ingested a toxic substance the day he became ill and that this substance caused vomiting. Symptoms and signs of encephalopathy then developed, and autopsy one month later demonstrated fatty changes in the liver and other organs. This pathogenesis could also be proposed in other patients reported to have had Reye's syndrome. In some, an exhaustive search for a toxic agent has been fruitless. It remains to be determined whether or not this syndrome constitutes a clinical pathologic entity with a single etiology. This candid case report illustrates one of the possible dangers of pneumography with the patient under Pentothal anesthesia.

RELIGION IN AMERICAN LIFE

The Editor's Soliloquy

That Quintessence of Dust

"The fool hath said in his heart, There is no God" (Psalm 53:1). Likewise the erudite atheist* denies God and disavows a future life. He is convinced there is no hereafter: no immortality of personal selfhood. From his temporal and terrestrial viewpoint, biological man as higher animal shares with the lower animals inevitable annihilation upon physiological death. Supporting his thesis he even quotes Scripture: "Dust thou art, and unto dust shalt thou return" (Genesis 3:19). His conviction is that upon his demise he will become an insensate corpse—doomed to revert to sheer dust. But since the human mind cannot conceive of total extinction of consciousness along with bodily disintegration, the atheist expects to retain just enough of a dim spark of life in his dust to be able to gloat: "See, I told you so! Here I am, a dried-up old corpse, decomposing into a glob of dust—nothing more!"

But from the immurement to which he has consigned himself and through the agency of that same faint but inextinguishable spark may he not have some misgivings when he senses the glorious immortality the rest of us are experiencing—we who scorned to end up as dust and elected to survive? As we enjoy our hereafter in the pursuit of the multitudinous pleasures, experiences and enlightenments which we had to forego during this life because of lack of time, opportunity and sufficient knowledge, may he not perhaps regret that his repudiation of the resurrection was so final and so irrevocable? We shall be experiencing ineffable and transcendent joys in our new dimension while the remains of him lie immobilized and isolated—too deep in the earth to be of any value even to a worm. He cannot join us in our dynamic and radiant self-fulfillment, for sterile static dust cannot enjoy the congeniality of friendship, the thrill to the challenge of sports; cannot appreciate the grandeur of a symphony, enter the absorbing world of generic knowledge or respond to the stimulation of travel throughout the universe.

While he, the non-believer, remains material dust, we, the believers, live a spiritual life beyond the grave. He has proved his point; we have proved ours. To his words from Genesis we have replied with Longfellow's lines: "Dust thou art to dust returnest, Was not spoken of the soul."

And so the ambivalent and cryptic question "And yet to me, what is this quintessence of dust?"** has been answered. To the atheist the quintessence is ALL; to us believers it is NOTHING! He has remained imprisoned in it; we have been released from it.

Carl O. Rice, M.D.

Old Doc Hess says: One of the smug hypocrisies of man is that respectability, which would rather look the other way than cause a fuss. C.O.R.

Surgeons

The best surgeon is he that has been well hacked himself.—Thomas Fuller

Mark Waters was a chain smoker. Wonder who'll get his office?

Too bad about Mark. Kept hearing the same thing everyone does about lung cancer. But, like so many people, he kept right on smoking cigarettes. Must have thought, "been smoking all my life... what good'll it do to stop now?" Fact is, once you've stopped smoking, no matter how long you've smoked, the body begins to reverse the damage done by cigarettes, provided cancer or emphysema have not developed. Next time you reach for a cigarette, think of Mark. Then think of your office —and your home.

MINNESOTA MEDICINE

HONOR AWARD

Minnesota Medicine Medical Writing Awards, 1968

It is the pleasure of the Board of Editors to announce the winners of the seventh annual Minnesota Medicine Medical Writing Awards chosen from articles published in MINNESOTA MEDICINE during the year of 1967.

The first place plaque is to be awarded to W. D. Snively, Jr., M.D. of Evansville, Indiana. His article "Mystery of the Milksick" appeared in the April issue of MINNESOTA MEDICINE, page 469. The presentation will take place during the annual meeting of the Minnesota State Medical Association in Rochester at the New Members, County Officers and Delegates Dinner on Sunday, May 12.

Certificates for excellence in medical writing will be awarded to the authors whose articles were felt to be particularly outstanding by the Board of Editors. These authors are listed on page 657.

Here's what you do to get samples of the

anticostive* hematinic

Your Prescription Blank

Dear Lederle
Send me samples
of Peritinic

℞

(Mail to Department 150
Lederle Laboratories,
Pearl River, New York 10965)

* anticostive, *adj.* (*anti* opposed to + *costive* causing constipation.) Against constipation. (Now isn't that a good idea in an iron-containing hematinic?)

PERITINIC®

Hematinic with Vitamins and Fecal Softener

A tablet-a-day provides:

● Elemental Iron (as Ferrous Fumarate)	100 mg
● Dioctyl Sodium Sulfosuccinate (to counteract constipating effect of iron)	100 mg
Vitamin B_1	7.5 mg
Vitamin B_2	7.5 mg
Vitamin B_6	7.5 mg
Vitamin B_{12}	50 mcgm
Vitamin C	200 mg
Niacinamide	30 mg
Folic Acid	0.05 mg
Pantothenic Acid	15 mg

Bottles of 60

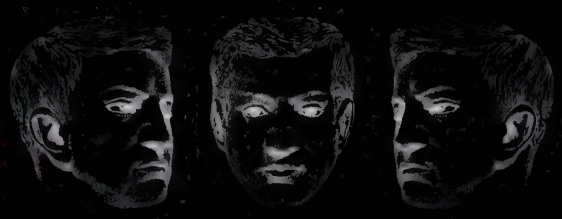
Sources of sinus headache

REGION OF SENSATION

FRONTAL SINUS—headache localized over the frontal region, commonly beginning in the morning. Eyes painful to touch, may be slight swelling over eyes, puffy eyelids.

SPHENOID SINUS—most difficult to diagnose. Headache or sense of pressure over vertex. May be pain in ear or mastoid region.

MAXILLARY SINUS—headache and tenderness under eyes at top of cheekbones, usually starting in early afternoon. Possible swelling of cheek. Pain in jaw and back teeth.



ETHMOID SINUS—headache, tightness in upper part of bridge of nose and well down its sides. Pain, deep-seated behind the eyes and in inner corners of the eyes.

TURBINATES—pain along medial and lateral walls of the inside of the nose. Headache in frontal region, along supraorbital ridge, a feeling of fullness in the head.

Source of symptomatic relief

SINUTAB

Sinus headache is often a reflection of congestion in the nasal mucosa. The pain that results in the various regions of the head may help in determining the particular structure(s) responsible. The Sinutab formula is specifically designed for symptomatic relief of sinus headache and nasal congestion. **Sinutab** *not only* **provides an effective decongestant** — to reduce mucosal engorgement and facilitate freer breathing — *and* **an antihistamine** — to help reduce edema and excessive secretions — but it *also* provides, in contrast to other leading decongestants, **two analgesics** for immediate relief of pain and discomfort.

And, too, the Sinutab dosage schedule of 2 tablets, *q.* 4 *h.* permits controlled and continuing analgesic relief.

Adverse Reactions: Epigastric distress, drowsiness, dizziness, insomnia and nervousness.

Precautions: Instruct patients not to drive or operate machinery if drowsiness occurs. Use with caution in patients with thyroid disease, heart disease, hypertension, diabetes or kidney disease. Excessive dosage or prolonged use may cause kidney damage.

Dosage: Adults—2 tablets every 4 hours.

Each tablet contains 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

SPECIFIC FORMULA **SINUTAB®** FOR SINUS HEADACHE

Also Available on Prescription:

Sinutab® with Codeine.* Each tablet contains 15 mg. (¼ gr.) codeine phosphate (Warning: May be habit forming), 150 mg. acetaminophen, 150 mg. phenacetin, 25 mg. phenylpropanolamine HCl, and 22 mg. phenyltoloxamine citrate.

Sinutab® Pediatric Suspension. Each 5 ml. teaspoonful contains 300 mg. acetaminophen, 12.5 mg. phenylpropanolamine HCl, and 10 mg. phenyltoloxamine citrate.

*Subject to Federal Narcotics Regulations.

For 1 complimentary bottle of 30 Sinutab tablets, write: J. S. Travis, Warner-Chilcott Laboratories, Morris Plains, N.J. 07950. Please mention this journal.

digestive disorders

B and C vitamins aid therapy: Nausea, vomiting, and severe diarrhea may seriously interfere with the digestion and absorption of nutrients. STRESSCAPS capsules, containing therapeutic quantities of vitamins B and C, may help meet the needs of these patients. In digestive disorders, as in many stress conditions, STRESSCAPS vitamins aid therapy.

334–B-6471

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg
Vitamin B_2 (Riboflavin)	10 mg
Vitamin B_6 (Pyridoxine HCl)	2 mg
Vitamin B_{12} Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100.

Curbstone Consultation

Carpal Tunnel Syndrome

QUESTION: On what basis does one make a diagnosis of carpal tunnel syndrome?

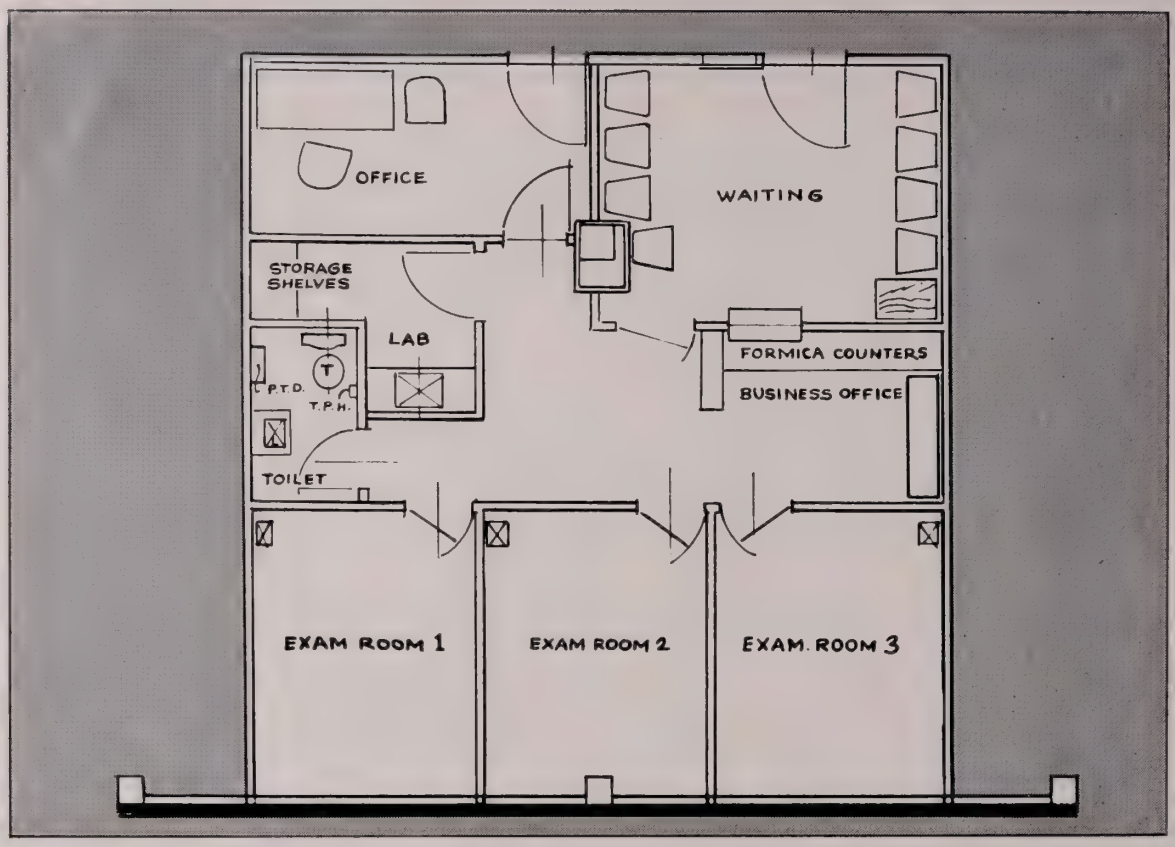
ANSWER: The symptoms related to the carpal tunnel syndrome are due to compression of the median nerve in the carpal tunnel of the wrist. The pain and numbness of the fingers which are noticed in this condition often result in mistaken diagnoses of scalenus anticus syndrome, compression of cervical nerve roots, and other like entities.

The carpal tunnel syndrome may be produced by any condition which restricts the size of the carpal tunnel or changes its contour. The diagnosis is made by demonstrating a positive wrist flexion test, a Tinel's sign over the median nerve at the wrist, and objective sensory findings limited to the median nerve distribution of the hand. Hypesthesia over the median nerve distribution to the hand is the most constant of the clinical findings. Atrophy of the three thenar muscles supplied by the median nerve may result in about half the cases. Surprisingly, there is seldom a history of injury as a cause of this syndrome. Swelling of the flexor synovialis produced by the peripheral vasodilatation that occurs during sleep has been postulated as being responsible for the symptom of "waking numbness" so characteristic of the syndrome.

Injection of a long-acting corticosteroid into the carpal tunnel may serve not only as an excellent diagnostic test, but as an effective method of treatment in this condition.

Harold D. Kletschka, M.D.
Houston, Texas

Invasion of Thoracic Wall



QUESTION: Is invasion of the thoracic wall associated with primary bronchogenic carcinoma a contraindication to surgery?

ANSWER: Perhaps ten percent of patients who undergo surgery for bronchogenic carcinoma will exhibit chest-wall invasion by tumor. This finding in itself is not a contraindication to surgery. When such cases have been subjected to what the surgeon felt was a curative en-bloc resection, as many as a third of such patients have been reported as surviving five years beyond surgery.

Harold D. Kletschka, M.D.

The Viewing Box

Hip Pain in a 13-Year-Old Girl

THE FILM is that of a 13-year-old girl who complained of right groin pain of progressively increasing severity for the previous five months. She gave no history of injury.

On physical examination, the right hip was tender to palpation, and she was unable to rotate it externally.

What is your diagnosis? (See below.)

Figure (top) anteroposterior pelvis and (bottom) frog pelvis.

Diagnosis: Slipped upper femoral epiphysis.

The left hip is normal. There is relative radiolucency of bony structures about the right hip, indicating that the patient is experiencing pain in the area and is guarding. The upper margin of the right upper epiphysis is flush with the femoral neck. On the frogged view the edge of the slipped epiphysis can be seen projecting beyond the inferior margin of the right femoral neck.

Slipped upper femoral epiphysis affects adolescents in the 10 to 17-year-old age group, a period of rapid growth and vigorous physical activity. Boys are more frequently involved than girls. There is usually no history of trauma.

The growing epiphyseal plate consists of four distinct layers: (1) resting cells, (2) proliferating cells, (3) hypertrophying cells, and (4) endochondral

ossification (zone of provisional ossification). The line of separation invariably occurs through the layer of hypertrophying cartilage. The intercellular matrix, which is responsible for the strength of the epiphyseal plate, is relatively scanty in this area. This is in contrast to the first and second layers where the matrix is abundant.

The exact cause of slipped upper femoral epiphysis is unknown. However, a hormone imbalance has been postulated. It is known that pituitary growth hormone will stimulate the proliferation of cartilage cells, while sex hormone will inhibit growth hormone and decrease the thickness of the epiphyseal plate. Slipping of the upper femoral epiphysis is felt to occur during a period in which exist excess amounts of growth hormone in relation to sex hormone.

In support of this theory, two body types are known to occur frequently among these patients: (1) Fröhlich's type of obesity (decreased sex hormone), and (2) the tall slender rapidly growing individual (increased growth hormone).

The attachment of the epiphysis is quite precarious during this period of growth, being weaker than bone, ligaments, tendons, and the fibrous joint capsule. In view of this, it is surprising that slipped epiphyses are not more common. The answer probably lies in the fact that only shearing forces are capable of producing epiphyseal slippage. The upper femoral epiphysis is the only one in the body normally subjected to shearing forces. Other diseases that predispose to epiphyseal separation are scurvy, rickets, and osteomyelitis.

When the epiphysis slips, it displaces posteriorly and inferiorly, while the femoral neck shifts upward and rotates outward. This results in varus deformity, adduction, and external rotation. The space produced between epiphysis and femoral neck eventually becomes filled with fibrous tissue, callus and cartilage. After a period of time the junction heals. If marked displacement is allowed to persist, degenerative changes become superimposed because of alteration of weight-bearing surfaces.

Clinical symptoms include groin discomfort and slight stiffness in early stages. As the degree of slip increases, pain and limp increase and limitation of internal rotation and adduction appear. If healing occurs with a displaced epiphysis, pain and spasm disappear but limp and varus deformity persist.

Roentgenologic findings in the earliest stage include swelling of the joint capsule, irregular widening of the epiphyseal line, and decalcification of the epiphyseal border of the metaphysis.

As displacement progresses, the head slips inferiorly and posteriorly. Normally the epiphysis extends a little above the superior border of the femoral neck. Minimal degrees of slipping can be detected by the upper border of the epiphysis becoming flush with the border of the neck. The continuity of Shenton's line is broken. The upper border of the femoral neck becomes smoothed off. Callus eventually fills in the space between head and neck.

Treatment begins with immediate cessation of all weight bearing. Most authorities feel that surgery in indicated as soon as the diagnosis is made. If the degree of slip is mild, fixation is accomplished by the insertion of pins without opening the joint. If the displacement is severe, the joint must be opened and the slip reduced before fixation.

Prognosis is excellent if fixation can be accomplished without manipulation or opening the joint capsule. As the extent of surgery increases, the risk of disruption of the blood supply with subsequent avascular necrosis likewise increases.

Fracture Conference

Acromioclavicular Separations

Dr. Einer Johnson:*

For the last half of our conference we will discuss the problem of acromioclavicular separation. We will first present six cases to illustrate the problem and the various forms of treatment and then follow with a discussion of the entire problem.

Report of Cases

Dr. Allen Schlein:**

Repair of Ligaments and Transfixion

The first case is that of a 26-year-old white male schoolteacher who had been in a single-car accident on September 27, 1959. The car had rolled over, and the patient's right

*Consultant, Section of Orthopedic Surgery, Mayo Clinic; Assistant Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

**Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

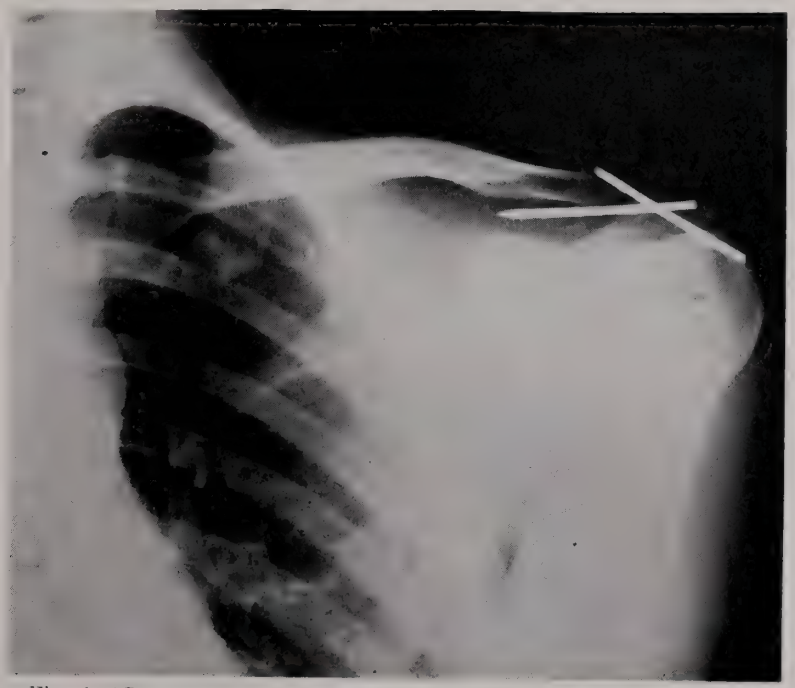

Fig. 1 (Case 1). Roentgenogram taken October 13, 1959, showing reduction of the acromioclavicular separation with two Kirschner wires.

arm had been caught outside the door and pinned to the ground. At the time of admission to the emergency room, he was noted to have a prominence of his distal left clavicle, which disappeared as he became recumbent. The diagnosis of acute left acromioclavicular dislocation was made. On October 5, 1959, an operative reduction was performed in which two threaded Kirschner wires were placed across the left acromioclavicular joint (Figure 1), and tears in the joint capsule and the trapezius muscle were repaired. The coracoclavicular ligaments were considered intact. A Valpeau dressing was applied postoperatively. The Kirschner wires were removed under local anesthesia on December 3, 1959. When the patient was last seen, on April 16, 1960, he was noted to have a slight prominence of the outer clavicle and grade 2 laxity of the acromioclavicular joint. He said he had no symptoms; he had a full range of motion.

Dr. Johnson:

This case is an example of acute acromioclavicular separation in which repair of the acromioclavicular ligaments plus transfixion with two threaded Kirschner wires was carried out. Note that the trapezius attachment was also torn and was repaired at the time of operation.

Dr. Schlein:

Hanging Cast and Pressure

The second case is that of a 16-year-old white boy who had been injured on October 4, 1963, when he had struck his right shoulder on the ground while playing football. On October 11, 1963, stress films revealed a complete acromioclavicular separation (Figure 2), and a closed reduction was performed. A cast was applied from the midpalmar crease to the axilla with the elbow at 90 degrees of flexion. Strips of elastic bandage (Elastoplast) were then placed over the clavicle, extending to the wrist of

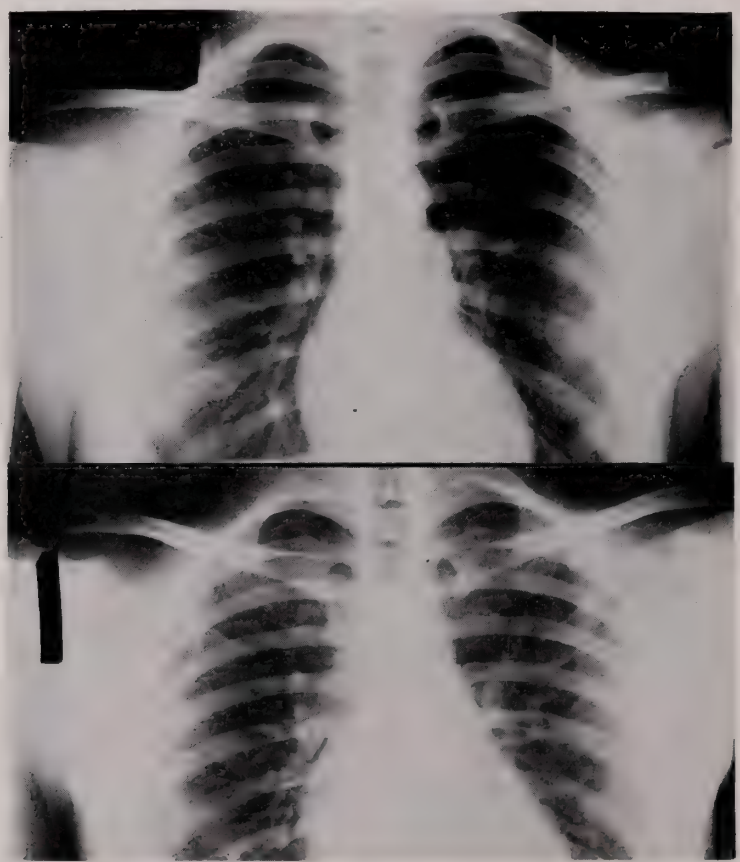

Fig. 2 (Case 2). *Upper,* Stress film taken one week after injury, revealing right-sided acromioclavicular separation. *Lower,* At two weeks after removal of plaster fixation.

the cast; this allowed the cast's weight to depress the outer end of the clavicle. The cast was removed three weeks later. The patient was again seen on November 27, 1963, when he stated that he had been playing volleyball for two weeks and had no complaints. There is no mention in the record of any palpable deformity, and the patient had a full range of motion.

Dr. Johnson:

This case illustrates treatment by closed or nonoperative means. A hanging arm cast was used and pressure was applied across the clavicle by means of a large pad. The cast was suspended from the shoulder in a fashion such that the pad compressed the clavicle, thereby reducing the acromioclavicular dislocation. This illustrates one of the many ways that downward pressure may be exerted on the clavicle by means of a cast.

Dr. Schlein:

Fascial Reconstruction of Coracoclavicular Ligament

The third case involved a 73-year-old white woman who was seen at the Mayo Clinic in June 1967 with the primary complaint of pain in the left shoulder and neck. In 1962 she had fallen on her left shoulder, sustaining a left acromioclavicular separation. Since then she had had progressively increasing pain and had noted a grating sound as her "shoulder" slipped in and out of place. On June 5, 1967, she underwent open reduction of her left acromioclavicular joint. Two threaded Kirschner wires were placed across the joint (Figure 3). The coracoclavicular ligaments were reconstructed with a fascia-lata graft. Postoperatively, a sling and swathe were applied. Except for some minor migration of one of the wires, the patient did well until 13 days after the operation, when her temperature suddenly increased to 102 F. Ultimately a diagnosis of infectious hepatitis was made, and she died in hepatic coma on July 29, 1967.

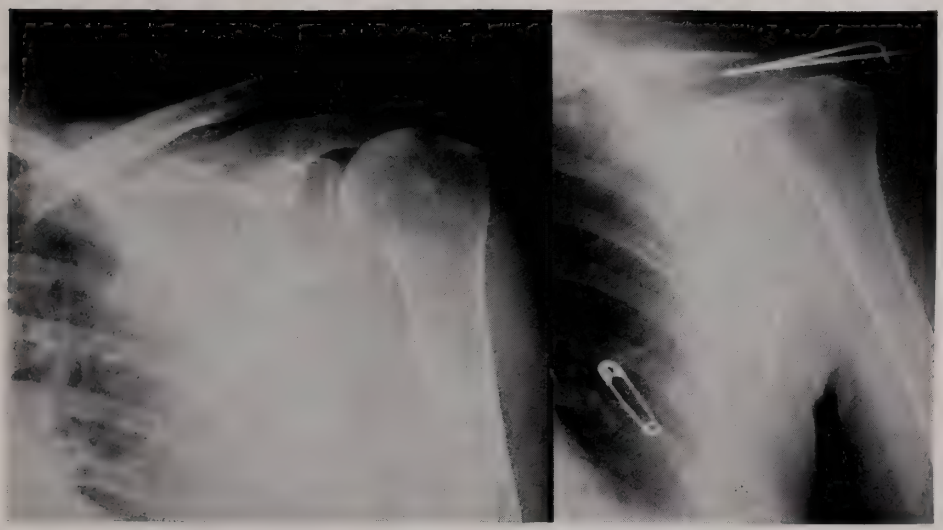

Fig. 3 (Case 3). *Left,* Preoperative roentgenogram showing old dislocation of left acromioclavicular joint. *Right,* Postreduction film, showing placement of two Kirschner wires across left acromioclavicular joint.

In the fourth case, a 65-year-old white man was first seen at this clinic on December 14, 1965, with the primary complaint of left shoulder pain after a car accident. Examination revealed grating of the left acromioclavicular joint and obvious upward displacement of the distal end of the left clavicle. Roentgenograms made while the patient held a 10-pound weight in each hand demonstrated a complete separation of the left acromioclavicular joint (Figure 4). On December 21, 1965, open reduction of the left acromioclavicular joint was performed. Three Kirschner wires were placed across the joint after it had been reduced, and the coracoclavicular ligaments were reconstructed with fascia lata. Postoperatively, a sling and swathe were applied. On February 24, 1966, the Kirschner wires were removed under local anesthesia. At the patient's last

visit, on July 14, 1966, he was noted to be asymptomatic; but his range of motion was five degrees less in all planes on the left compared to the right. At the end of 1967, the patient reported by letter that he was doing well and was completely asymptomatic.

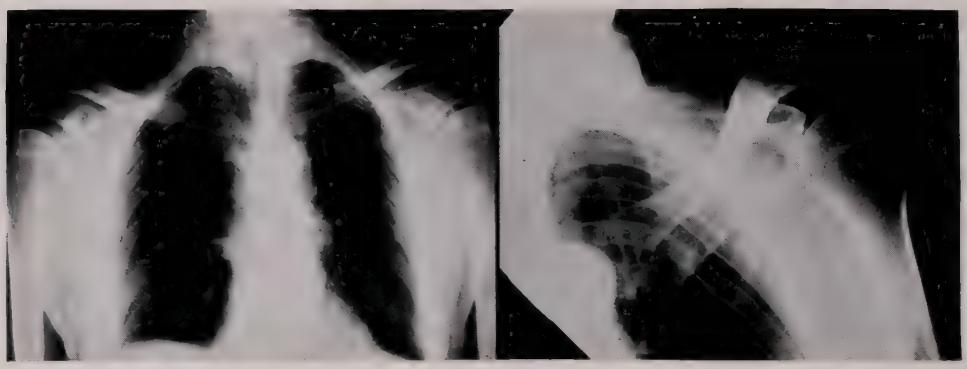

Fig. 4 (Case 4). *Left,* Stress film, revealing dislocated acromioclavicular joint on the left. *Right,* At six weeks after removal of Kirschner wires.

Dr. Johnson:

These last two cases illustrate the use of fascial reconstruction of the coracoclavicular ligaments in a chronic and a complete acromioclavicular separation.

Dr. Schlein:

Excision of Outer End of Clavicle

The fifth case is that of a 39-year-old white male ranch hand who had been thrown from a horse in July 1958. He had landed on his left shoulder and had noted the immediate onset of pain, deformity, and limitation of motion. A sling had been applied by his local physician. His symptoms became progressively worse and he came to this clinic in December 1958 (Figure 5). The distal one inch of the left clavicle was excised and a sling and swathe were applied; shortly thereafter he was dismissed from the hospital. In March 1959 his local physician reported that the patient had returned to heavy ranch work but was somewhat bothered by the deformity of his shoulder.

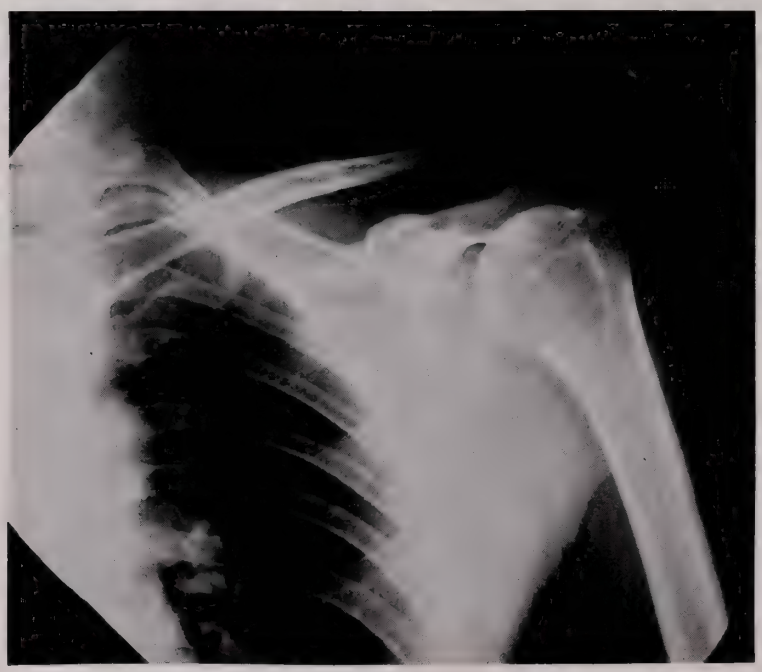

Fig. 5 (Case 5). Preoperative roentgenogram made six months after injury.

Dr. Johnson:

This case illustrates a complete acromioclavicular separation of long duration, which was treated by excision of the outer end of the left clavicle. The patient did not have the weakness of the shoulder which sometimes occurs after this operation, and at the present time he is doing heavy labor without difficulty.

Dr. Schlein:

No Treatment

The sixth case is that of a 24-year-old white man who had been in a car accident on January 23, 1967. In addition to other injuries, he had had an acute left acromioclavicular separation (Figure 6) which had been largely ignored while his more pressing injuries were treated. By December 1967 (11 months after the accident) he had no shoulder symptoms, had ceased to be sensitive about the cosmetic change in the shoulder, and desired no treatment for the now chronic, complete acromioclavicular separation.

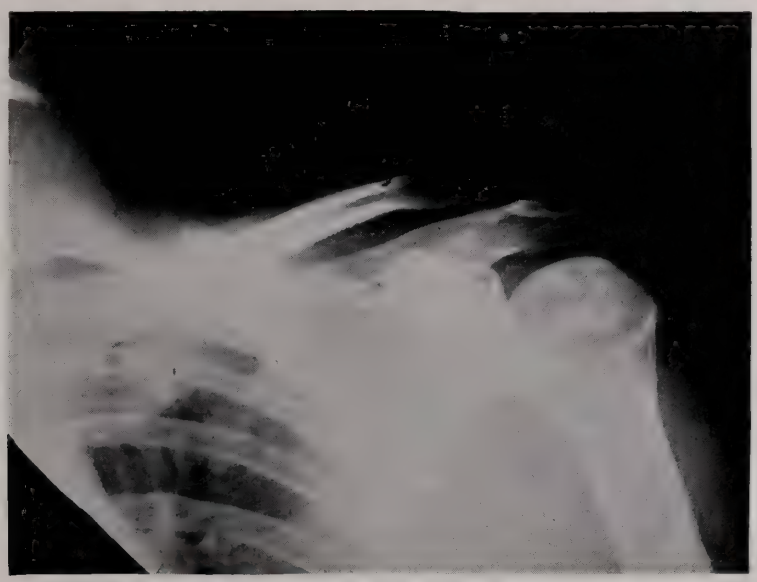

Fig. 6 (Case 6). Dislocation of left acromioclavicular joint.

Dr. Johnson:

Although this patient had symptoms when he was first seen, he ultimately developed full function in the shoulder without weakness or symptoms and elected not to have treatment for his acromioclavicular separation.

Discussion

Dr. Schlein:

The acromioclavicular joint is a small joint of debatable biomechanical importance but of definite literary importance if one considers the amount written on its malfunction. Anatomically it is a synchondrosis containing a small cartilaginous disk and is enclosed by a synovial capsule. A thickened supporting portion of the capsule is known as the acromioclavicular ligament. The structural integrity of the acromioclavicular joint is also somewhat dependent on both the coracoclavicular ligaments and the clavicular attachment of the trapezius and deltoid muscles. However, the acromioclavicular joint may be dislocated completely without any disruption in the integrity of the coracoclavicular syndesmosis.

Complete separation of the acromioclavicular joint occurs in every age group but is commonest in the athletically inclined male between the ages

of 15 and 30 years. The mechanism of injury is a fall or a blow directed over the point of the shoulder, followed by pain, deformity, and limitation of motion.

The typical deformity is comprised of prominence of the clavicle, drop of the shoulder downward and forward, and development of a wide sulcus between the clavicle and the acromion process.

The lesion is usually produced by rupture of the acromioclavicular ligament, perhaps associated with disruption of the coracoclavicular syndesmosis and avulsion of the clavicular attachments of the deltoid and trapezius muscles.

The prereduction roentgenogram usually reveals complete displacement of the articular surfaces of the clavicle and acromion process, increase in the coracoclavicular interval, and downward and forward displacement of the scapula. In some cases, this deformity may be demonstrated only by stress roentgenograms made while the patient is standing upright and holding a 10- or 15-pound weight in each hand. About 5 to 6% of all acromioclavicular separations are complicated by regional fractures.

Conservative Treatment

Most authors agree that subluxation of the acromioclavicular joint does not require surgery, but controversy does exist concerning the treatment of complete dislocation of this joint. Many authors think that the acromioclavicular dislocation can be best treated conservatively. In 1946 Urist stated that 36 methods of conservative therapy had been described in the literature. They included various bandages, adhesive dressings, harnesses and braces, and suspension casts. There are many superficial differences in these appliances but all are designed to depress the clavicle and restore the integrity of the acromioclavicular joint.

Nonsurgical Therapy

The advocates of conservative therapy think that good results can be obtained in 80 to 85% of patients without resorting to a surgical procedure. They also think that surgery has disadvantages in that (1) there will be an operative scar, (2) usually more than one operative procedure may be required, (3) resultant degeneration of the acromioclavicular joint may occur secondary to transfixion, (4) the metallic fixation device may migrate or break, (5) prevention of clavicular rotation sometimes results secondary to lag-screw fixation of the coracoclavicular syndesmosis, (6) there is a possibility of increase in coracoclavicular ligament calcification, and (7) there is a significant incidence of inability to maintain the anatomic reduction after the metallic fixation is removed. The results of conservative therapy of this lesion are difficult to evaluate because of the small size of most published series, such as that of Urist in 1946 and that of Stubbins and McGaw in 1959.

Surgical Therapy

The role of surgical treatment is also somewhat clouded by accounts of more than 30 different surgical procedures in the literature. However, all these procedures are based on acromioclavicular suture, coracoclavicular suture, coracoclavicular fixation, ligamentopexy, or excisional surgery. Two creditable attempts have been made to analyze the results in the various types of surgical procedure. The first, in 1961, was by Lazcano, Anzel, and

Kelly at the Mayo Clinic, and the second was by Wilson of Columbia University and Prothero of North Carolina University at Chapel Hill. Both groups concluded that the greatest number of poor results occurred after metallic fixation of the acromioclavicular joint. It was also noted that the best functional results were obtained after excision of the distal part of the clavicle and the best cosmetic results after coracoclavicular fixation with a lag screw.

In conclusion, we can only state that the large number of methods available for treatment of this lesion indicates there is not as yet a single best method for all patients.

Dr. Johnson:

As suggested by the number of methods of treatment presented in the literature, this is not an easy problem, nor is it one about which there is unanimous thought. Dr. Schlein did not make a point of the difference between acute and chronic acromioclavicular separations, but most writers define the separation as chronic if it has persisted for longer than 14 days. There also seems little doubt that there is both a partial and a complete separation. In partial separation, only the acromioclavicular joint capsule ligaments are ruptured and the clavicle is allowed to elevate up out of the acromioclavicular joint. These patients do not have the marked upward dislocation of the clavicle seen in the complete acromioclavicular separations, but they do have local tenderness over the acromioclavicular joint and will often have a palpable sulcus. The complete acromioclavicular separations are those in which not only the capsule and ligaments rupture but there is also rupture of the conoid and trapezoid portions of the coracoclavicular ligament. This allows the clavicle to ride high with nothing to hold it—no tethering effect by the capsule or the ligaments—and produces a marked upward dislocation of the clavicle, which is obvious on inspection.

By presenting these six cases we have tried to illustrate the various forms of treatment and to give some idea of the results obtained. We did not show a case treated by a lag screw inserted across the coracoclavicular joint. This is surely an acceptable method but one which is not technically easy. The lag screw should be removed after healing of the coracoclavicular ligaments, in six to nine months.

There is no one successful way to treat this problem, and the method chosen by any one physician often depends on his previous experience. If I were to see an acromioclavicular separation in a young athlete, I would surely try to treat it conservatively by some mechanism which produces downward pressure on the clavicle, in the hope of being able not only to gain reduction of the dislocation but to maintain it long enough for the ligaments to heal. However, if I were unsuccessful in this, I would not hesitate to do a fascial reconstruction of the coracoclavicular ligaments. Although there are many other ways of treating acromioclavicular separations, these have been the methods that have served me best. Dr. Kelly, you have written a paper on this problem; what are your thoughts?

Dr. P. J. Kelly:

I agree with you as far as your classification of these injuries is concerned, but I would add a third class in which there is not only complete

rupture of the coracoclavicular ligaments and capsule about the acromioclavicular joint but also avulsion of the deltoid and trapezius muscle insertions. This, I believe, is the third stage of this injury. It is the most severe form and presents the most serious challenge to treatment. When we reviewed the cases at the Mayo Clinic, we found that this problem did not have an easy solution and the treatment for an individual case was almost always dependent on the past experience of the orthopedic consultant in charge.

Dr. M. B. Coventry:

The manner in which this problem has been presented makes it seem simple and easy to determine whether the dislocation of the acromioclavicular joint that has occurred is complete or partial. But making this determination has not always been easy for me. Those cases in which there is only partial rupture of the acromioclavicular joint are much easier to treat, and the success rate is much higher. When one reviews the literature, he is not always able to tell whether the author of the article has made this distinction between complete and partial dislocations, and I sometimes wonder if the end results have not been confused for this reason. I would urge that the physician try to make the differential diagnosis between complete and partial dislocations, because the prognosis for one is a good deal different from that for the other.

Dr. Johnson:

In summary, let me say that this is not an easy problem and the results of treatment are not always satisfactory but are entirely dependent on the extent of the damage which occurs at the time of the injury.

Low Status of 16th Century Medicine

Now-a-days it is apparent to see how Tinkers, Tooth-drawers, Pedlars, Ostlers, Carters, Porters, Horse-gelders and Horse-leeches, Idiots, Apple-squires, Broommen, Bawds, Witches, Conjurers, Soothesayers, and Sow-gelders, Rogues, Ratcatchers, Runagates and Proctors of Spittle houses with such other like rotten and stinking weeds which do in Town and country, without order, honesty or skill, daily abuse both physic and surgery, having no more perseverance, reason or knowledge in this art than hath a goose, and most commonly useth one remedy for all diseases and one way of curing to all persons both old and young, men, women and children which is as possible to be performed or to be true as for a shoe-maker with one last to make a shoe to fit for every man's foot and this is one principal cause that so many perish.—William Clowes

---

Experience is good medicine, but it is never taken until the sickness is over.
—German proverb

Dermatology

Poison Ivy

(Rhus Dermatitis)

RHUS DERMATITIS is the most common contact dermatitis in the United States. This group of plants accounts for as much allergic contact dermatitis as all other contactants combined. Four main groups of plants are responsible: common poison ivy (Rhus radicans) has general distribution throughout the United States; oakleaf poison ivy (Rhus diversiloba) is found in the Southeast; Western poison oak (Rhus toxicodendron) is found on the Pacific coast, and poison sumac (Rhus vernix) is distributed in swampy areas throughout the country. In the Midwest, undoubtedly the majority of cases are due to common poison ivy. These plants may be found anywhere and have even been inadvertently cultivated by gardeners.

A characteristic of this group of plants is that the same sensitizing antigen is common to all. Therefore, cross sensitivity exists among all members of the poison Rhus group and the resulting allergic contact dermatitis is the same. Of interest is the fact that the Rhus group belongs to the same family

Figure

of plants as the Japanese lacquer tree, cashew nut, and mango, to which cross reactions may occur. The common antigenic substance is an oleoresin found in the sap and called urushiol. It is present in the leaves, stems, fruit and roots. Even after the plant is dead this substance may be extracted and has full antigenic properties. Some investigators believe the dermatitis-producing element in this oleoresin to be a pentadecylcatechol (1,2-dihydroxybenzene).

With casual exposure, sensitivity to the Rhus group of plants occurs in 70 percent of the population. If the contact is more prolonged, most individuals would acquire this sensitivity. Susceptibility tends to be greater in fair-complexioned individuals. Patch testing is to be avoided in suspected Rhus allergy, for it may sensitize the individual and is usually not necessary for diagnosis. Clinically, the eruption is very pruritic and is characterized by erythema, edema, papules, vesicles and bullae (Figure). Linear streaking is often present and is of diagnostic help. Usually the eruption appears within one to two days after contact; however, on rare occasions, the onset may be as soon as eight hours or delayed for eight to 10 days. These variances are probably dependent upon susceptibility, extent of exposure and site of contact. The antigen enters within 10 minutes after the oleoresin contacts the skin. Therefore, washing after known or suspected contact with the plant must be prompt if it is to help in preventing the eruption or limiting its severity. Even if this cannot be accomplished, the individual should bathe as soon as possible to remove any residue of the oleoresin. A problem with Rhus oleoresin is that it may contaminate animal fur, clothing and other articles, thereby producing the dermatitis as effectively as if the individual contacted the plant directly. Simple washing with soap or detergents usually removes the oleoresin from these objects.

In the management of mild poison-ivy eruptions one may employ antipruritic shake lotions and oral antihistamines. Topical cortisone sprays can also give relief. Large vesicles may be opened. It is noteworthy that the content of such vesicles is not antigenic and cannot spread the eruption. Colloid baths are helpful and usually welcomed by the patient. If the eruption is more severe with widespread involvement, cool compresses may be used in addition to the treatment already mentioned. At times these eruptions may become generalized and the patient disabled. When this occurs, hospitalization and systemic steroids can aid in hastening recovery.

Prevention of Rhus dermatitis is best achieved by avoidance of contact with the plant. However, in some occupations the risk of contact is high, and in these situations the question of hyposensitization arises. Certain points should be remembered concerning this procedure. First, it does not give complete protection nor is it uniformly successful. Further, it is only temporary and the original sensitivity returns within six months. Another important point to remember is that this procedure must never be used when the patient has active poison-ivy dermatitis, for wide dissemination may ensue. As to date, no topical applications exist which can effectively protect the susceptible individual from this dermatitis. Therefore, recognition of the plant and avoidance remain the ideal prophylaxis.

The solar system has no anxiety about its reputation.—Ralph Waldo Emerson

Abbott Antihypertensive Building Blocks

A simplified approach to the practical management of hypertension

Enduron: (methyclothiazide) A basic building block for mild hypertensives

Excellent day-long Na^+ output, yet easy on the K^+

Enduron provides an excellent starting therapy. Your patient's sodium excretion is greatly enhanced. Yet potassium loss is low.

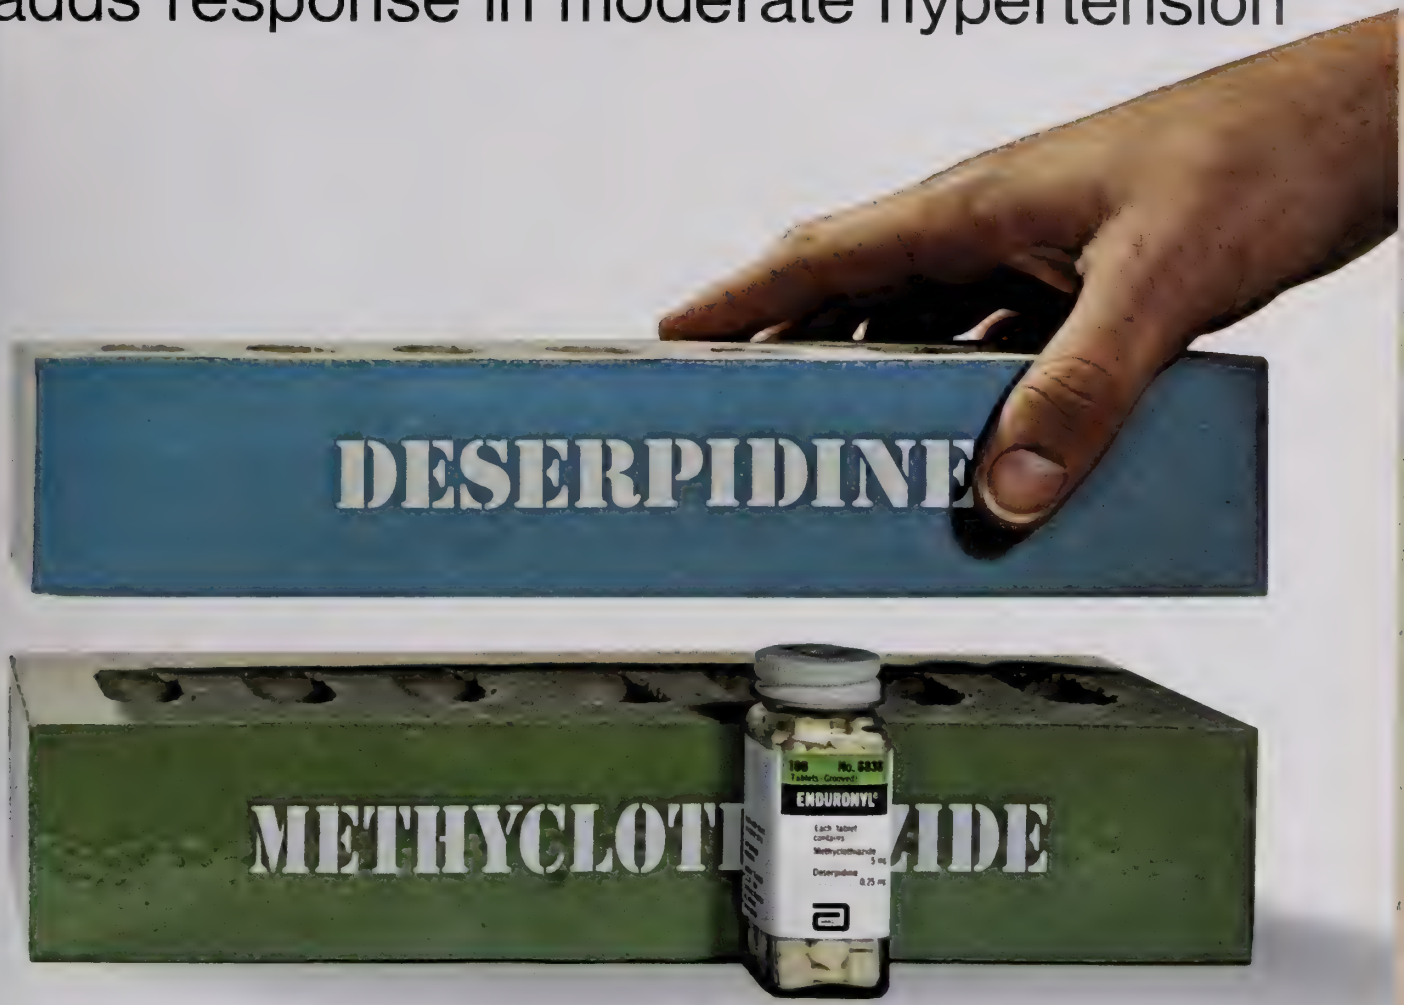
The therapeutic action is smooth, and persists for a full 24 hours. With Enduron you can prescribe convenient once-a-day dosage without skimping your patients on day-long thiazide effectiveness.

Of course, as with all thiazides, supplemental dietary potassium should also be considered.

Use Enduron as a basic therapy in patients with mild to moderate hypertension. A single 5-mg. tablet each day is ample in most cases.

Once a day, every day

ENDURON®



METHYCLOTHIAZIDE

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

Enduronyl: Its deserpidine component adds response in moderate hypertension

Less frequent rauwolfia side effects than with reserpine

When you wish to build further response, consider shifting to Enduronyl.

Enduronyl adds a building block of *deserpidine*. This is a purified rauwolfia alkaloid available only from Abbott. It adds good antihypertensive and tranquilizing activity. Yet its incidence of untoward effects, particularly lethargy and depression, is lower than with reserpine.

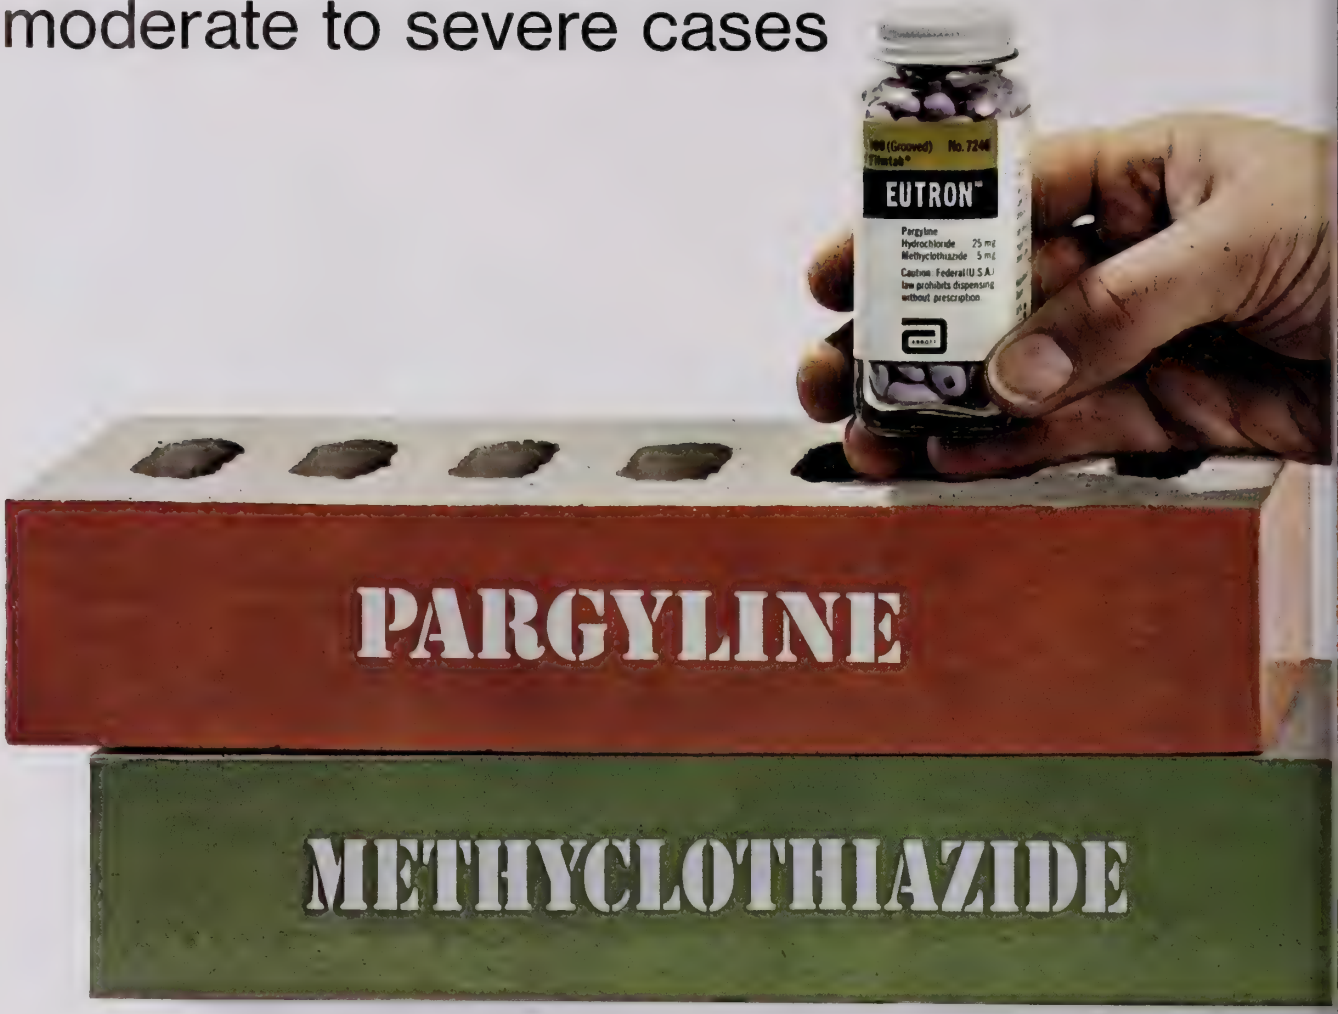
Enduronyl is available plain or Forte. The latter provides its variation where most helpful, by doubling the deserpidine.

Use Enduronyl for patients throughout the broad range of mild to moderately severe hypertension.

Once a day, every day

ENDURONYL®

METHYCLOTHIAZIDE 5 mg. with
DESERPIDINE 0.25 mg. or (FORTE) 0.5 mg.



MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

801094

Eutron: A unique combination for handling moderate to severe cases

Affords almost uniform diastolic reduction in all body positions

Eutron lowers diastolic pressures nearly equally, whether your patient is standing up or lying down.

Thus, in clinical trials, average *standing* diastolic readings were reduced from 112 pre-treatment to 90 post-treatment; *sitting* from 115 to 95; and *recumbent* from 112 to 94.

Note that following Eutron, the diastolic reductions were nearly alike in all three body positions.

Use Eutron for managing your moderate to severe cases. Its building blocks enhance each other; hence lesser doses often suffice.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 mg.
with METHYCLOTHIAZIDE 5 mg.

MILD TO MODERATE TO SEVERE

See Brief Summary on final page of advertisement

ENDURON® | ENDURONYL®

METHYCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg.

Indications: Edema and mild to moderate hypertension (Enduron), and mild to moderately severe hypertension (Enduronyl). More potent agents, if added, can be given at reduced dosage.

Contraindications: Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease or impending hepatic coma (hepatic coma due to hypokalemia has been reported in patients on thiazides). Do not use Enduronyl in severe mental depression, suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity where there is history of allergy or asthma. If added potassium is indicated, dietary supplementation is recommended. Reserve enteric-coated potassium tablets for cautious use only when necessary, as they may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation often requiring surgery; discontinue them immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occurs. Neither Enduron nor Enduronyl contains added potassium.

Precautions: Use thiazides cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery, thiazides may reduce response to vasopressors, and increase response to tubocurarine. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia) in all patients. In hypokalemia (especially in digitalized patients) give supplemental potassium. In hypochloremic alkalosis, give supplemental chloride.

Use rauwolfias with caution in patients with history of peptic ulcer. Rauwolfias with anesthetics may produce hypotension and bradycardia. Discontinue Enduronyl two weeks before elective surgery. Consider vagal blocking agents during emergency surgery. In epilepsy, adjust anticonvulsant dosage. In electroshock, shorten stimulus strength and duration. In occasional patients with depressive tendencies, rauwolfias may precipitate severe mental depression that usually disappears when drug is stopped.

Adverse Reactions: Thiazide reaction include blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, serum uric acid or blood sugar; anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, symtomatic gout, and pancreatitis. Cutaneous vasculitis in the elderly has been reported with other thiazides. Adverse effects with deserpidine are qualitatively similar to those with reserpine, but their incidence is lower. These include nasal stuffiness, abdominal cramps or diarrhea, nausea, headache, weight gain, reduced libido and potency, peptic ulcer aggravation, epistaxis, skin eruption, asthma in susceptible patients, electrolyte imbalance, excessive salivation, and a reversible Parkinson's syndrome. Excessive drowsiness, fatigue, weakness, and nightmares may signal mental depression. Thrombocytopenia, purpura, and a symptom manifested by dull sensorium, deafness, uveitis, glaucoma, and optic atrophy are rare allergic reactions to other rauwolfias. Hypotension from antihypertensive agents may precipitate angina attacks in susceptible individuals. Usually adverse reactions disappear when drug is withdrawn.

EUTRON™

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications—Moderate to severe hypertension.

Contraindications—Pheochromocytoma, paranoid schizophrenia, hyperthyroidism and advanced renal failure. Not recommended in malignant hypertension, children under 12, pregnant patients.

Do not use with: centrally or peripherally acting sympathomimetic drugs; foods high in tyramine (e.g., aged and natural cheeses); parenteral reserpine or guanethidine; imipramine, amitriptyline, desipramine, nortriptyline or their analogues; other monoamine oxidase inhibitors; methyldopa or dopamine; separate Eutron and these agents by two weeks.

Sensitivity to thiazides; severe renal disease (except nephrosis) or shutdown; severe hepatic disease; impending hepatic coma from thiazide-induced hypokalemia.

Warnings—Patients: 1. No other drugs (particularly "cold preparations" and antihistamines), cheese or alcohol without physician's consent. 2. Promptly report orthostatic symptoms, severe headache, other unusual symptoms. 3. Angina pectoris or coronary artery disease patients must not increase physical activity with improved anginal symptoms or well-being.

Physicians: 1. Use antihistamines, hypnotics, sedatives, tranquilizers and narcotics (meperidine contraindicated) cautiously in reduced doses. 2. Stop Eutron two or more weeks before elective surgery; in emergency surgery reduce premedication (narcotics, sedatives, analgesics, etc.) to 1/4 to 1/5; carefully adjust anesthetic dosage to patient response. 3. Use cautiously in advanced renal failure. 4. Pargyline may induce hypoglycemia. 5. Consider possible sensitivity reactions when a history of allergy or asthma is present. 6. If potassium is indicated, dietary supplement is recommended; enteric-coated potassium tablets may induce serious or fatal small bowel lesions (stenosis with or without ulceration), cause obstruction, hemorrhage, and perforation frequently requiring surgery; discontinue medication immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occurs; Eutron does not contain added potassium. 7. Possible systemic lupus erythematosus has been reported for thiazides.

Precautions—Pargyline: Use cautiously at reduced dosage: caffeine, alcohol, antihistamines, barbiturates, chloral hydrate, other hypnotics, sedatives, tranquilizers, narcotics. Periodically do urinalyses, blood counts, liver function tests, etc. Use with caution in liver disease. Watch for orthostatic hypotension, especially in impaired circulation (e.g., angina pectoris, coronary artery disease, cerebral arteriosclerosis); also, augmented hypotension in concomitant febrile illnesses. Reduce or discontinue if hypotension is severe. In impaired renal function watch for cumulative drug effects, elevated BUN and other evidence of progressive renal failure; withdraw drug if these persist. In surgery increased central depressant response (hypotension and increased sedative effect) can be controlled by (1) discontinuing at least two weeks prior; (2) in emergency surgery lowering dose of premedication; (3) when necessary, administering a vasopressor. Do not use in hyperactive and hyperexcitable patients. Pargyline may unmask severe psychotic symptoms where emotional problems pre-exist. Use cautiously in Parkinsonism, especially with antiparkinsonian agents. In prolonged therapy, examine for change in color perception, visual fields, fundi and visual acuity. Also, prolonged therapy has made certain patients refractory to nerve blocking effects of local anesthetics.

Methyclothiazide: Use cautiously in severe renal dysfunction, impaired hepatic function or progressive liver disease; also in pregnancy (bone marrow depression, thrombocytopenia, and altered carbohydrate metabolism have been reported in certain newborn). In surgery thiazide may reduce vasopressor response and increase tubocurarine response. Antihypertensive response may be enhanced following sympathectomy. Watch for electrolyte imbalance (e.g., hyponatremia). Give supplemental chloride if hypochloremic alkalosis occurs and supplemental potassium if hypokalemia occurs (especially in digitalized patients). Thiazides may decrease serum P.B.I. without signs of thyroid disturbance.

Adverse Reactions — Pargyline: Orthostatic hypotension and associated symptoms, mild constipation, fluid retention, edema, dry mouth, sweating, increased appetite, arthralgia, nausea, vomiting, headache, insomnia, difficult in micturition, nightmares, impotence, delayed ejaculation, rash, purpura, weight gain, hyperexcitability, increased neuromuscular activity and other extrapyramidal symptoms. Drug fever is extremely rare. Reduction in blood sugar and hypoglycemic effects are possible. Congestive heart failure has been reported in a few patients with reduced cardiac reserve.

Methyclothiazide: Blood dyscrasias (thrombocytopenia with purpura, agranulocytosis, aplastic anemia); elevation of BUN, blood sugar or serum uric acid (gout may be induced); anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice and pancreatitis. Cutaneous vasculitis in elderly patients has been reported with other thiazides.

If side effects are severe or persist, reduce dosage or withdraw drug. 804438R

Tumor Conference

Chondrosarcoma of the Sternum*

TUMORS OF THE thorax comprise about seven to ten percent of all bony tumors in most collected series.[1,3] Primary lesions of the sternum are relatively rare, representing only twelve to twenty percent of this entire group of chest wall tumors. In a survey of 144 tumors of the bony thorax from the Mayo Clinic[4] only 18 were found to involve the sternum primarily. Chondrosarcomas were most commonly encountered, but the other malignant tumors included myeloma, reticulum cell sarcoma, and osteogenic sarcoma. Only one was considered benign and 10 of the 18 patients were dead of the tumor at follow-up. However, only two of the 18 patients had been treated by radical resection.

Presenting Symptoms

Sternal neoplasms most often occur initially with progressive swelling over either the manubrium or sternal area with subsequent development of pain in about one third of the cases. Examination usually discloses a fixed, sometimes tender mass which may be fluctuant. Chest x-rays may indicate localized bony destruction and encroachment of the anterior mediastinal space.

The gross and microscopic features of chondrosarcomas involving the sternum have been thoroughly documented by Dahlin and Henderson.[1] Their course is similar to that of chondrosarcomas in other locations, growing slowly by direct extension and recurring locally if incompletely removed. They also have the potential to metastasize widely, especially in lesions of higher grade malignancy.

Treatment

Principles of treatment depend upon early diagnosis and total excision of the tumor followed by chest wall reconstruction. Although only a few cases have been reported, a high proportion of patients treated in this manner should be salvaged.

The following case report illustrates the problem presented by a large sternal chondrosarcoma and the technique used for its successful removal and chest wall reconstruction.

*Presented at the Minnesota Surgical Society Meeting, Duluth, Minnesota, July, 1967.

Case Report

A 51-year-old woman was admitted to St. Mary's Hospital, Minneapolis, on November 29, 1966, complaining of a painless swelling in the upper sternal area of six months' duration. She also noted generalized weakness, anorexia, mild dyspnea, aching in the right shoulder, and occasional rectal bleeding, all of recent onset. She had spontaneously gained 45 pounds during the previous year. She had a small cystocele and rectocele but otherwise had been in excellent health.

Physical Findings

Physical examination disclosed a well nourished lady in no distress, with normal pulse and blood pressure. There was a 4 x 6-centimeter firm, smooth, slightly tender mass replacing the major portion of the manubrium and the upper sternum and centered more to the right than to the left. There were a few bilateral expiratory rhonchi with deep, rapid respirations; there were normal cardiac sinus rhythm and no murmurs. The right lobe of the liver descended two finger breadths below the right costal margin with deep inspiration and was moderately firm and smooth. Rectal and pelvic examinations were negative.

Laboratory Studies

Routine laboratory studies were within normal limits. Two-hour postprandial blood sugar level was 121 mg. per cent. Other studies, including serum glutamic oxaloacetic transaminase, lactic dehydrogenase, urea and latex agglutination, were negative. Electrocardiograms repeatedly showed abnormal ST depressions in V2, 3 and 4.

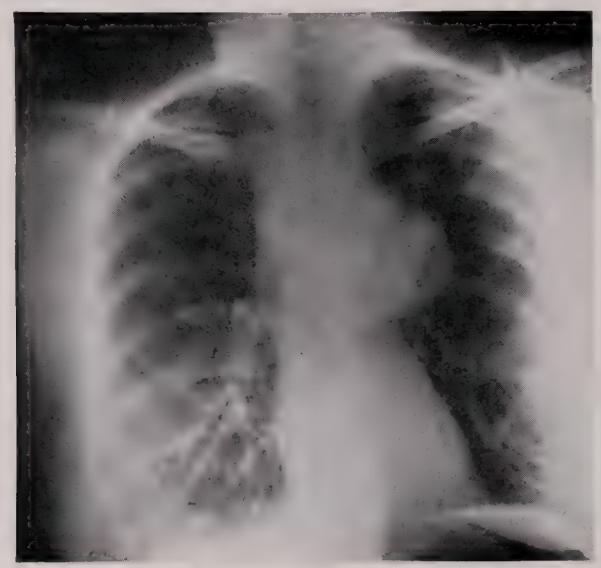

Fig. 1—Posteroanterior chest roentgenogram.

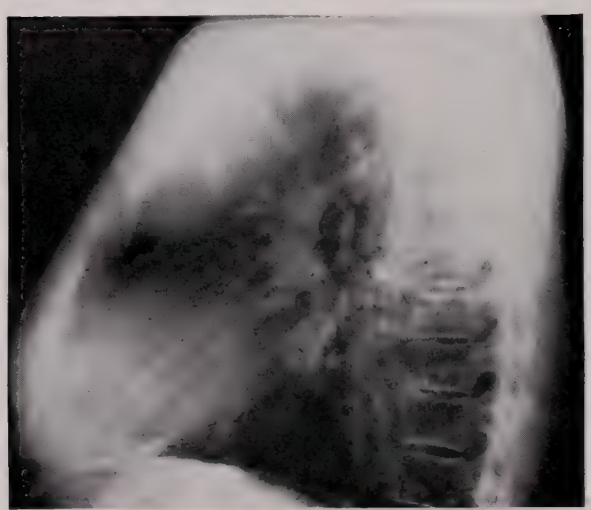

Fig. 2—Right lateral chest roentgenogram.

The posteroanterior chest x-ray (Figure 1) showed a large mass lesion superimposed on the left hilum, and the right lateral view (Figure 2) confirmed its anterior position and demonstrated definite destruction of the upper sternum and manubrium. The remaining lung fields were normal. The cervical spine x-ray showed disc space narrowing at the C3, 4, and 5 levels with associated degenerative changes.

A Silverman needle biopsy, on December 2, 1966, revealed the tumor to be a low-grade chondrosarcoma.

The Operation

Operative removal of the entire tumor was accomplished on December 5, 1966, in the following manner:

The patient was placed in the right lateral decubitus position and a preliminary left thoracotomy performed, widely resecting the seventh rib for future use. The tumor was found to fill the entire retrosternal space but appeared to be quite resectable (Figure 3). The thoracotomy incision was then closed and the patient placed in the supine position. A transverse incision was made over the central portion of the sternum, and large superior and inferior flaps were dissected free superficial to the muscle and facial layers. The pectoral fascia was incised vertically over the lower part of the sternum, and the attachments of the pectoral muscles dissected off laterally over the costal cartilages and ribs as far as necessary to obtain good exposure of the operative area. Superiorly, muscle attachments were sacrificed over the tumor area. The heads of the clavicles were dissected free, and the periosteum was stripped away from the medial 4 or 5 centimeters. The left fourth costal cartilage was then divided and the anterior mediastinal space entered. By working both inferiorly and superiorly,

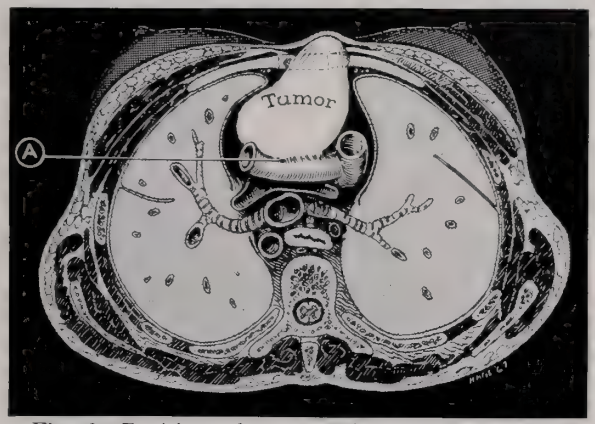

Fig. 3—Position of tumor with attachment to innominate vein (A).

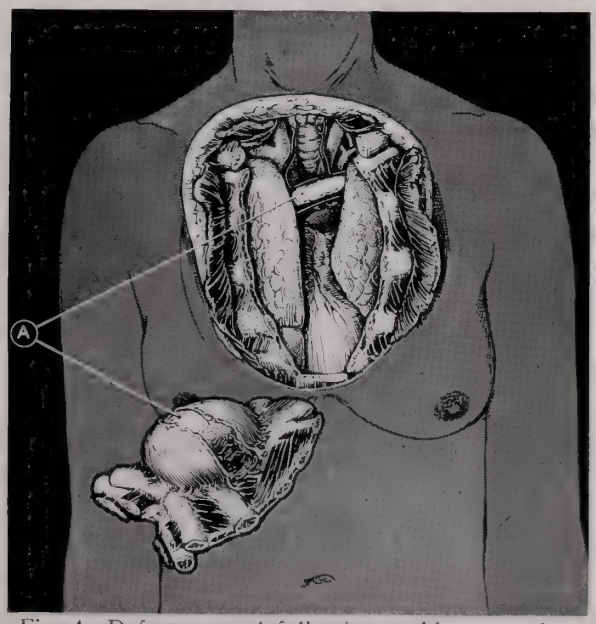

Fig. 4—Defect created following en-bloc resection.

the incision was gradually enlarged by dividing the medial heads of the first, second and third ribs on the left. The left clavicle was then transected 5 centimeters lateral to the costal clavicular junction. Dissection was carried out on the right side exactly as on the left. The internal mammary arteries were ligated. The sternum was divided inferiorly using a Gigli saw just below the fifth costal cartilage. The inferior cut edge of the sternum was elevated, and dissection in the fibroareolar tissue anterior to the pericardium allowed removal of all fatty and nodal tissue. Superiorly, the tumor was dissected off the innominate vein to which it was intimately attached. The internal mammary arteries were ligated at their origin from the subclavian arteries. The right clavicle was transected, and the tumor removed en bloc (Figure 4). The entire defect measured 16 x 14 centimeters. An 18 x 24 centimeter sheet of fascia lata was removed from the left anterolateral thigh through a long vertical incision. Two catheters were placed in each pleural cavity and the fascia sutured in place over the defect under tension. The previously removed rib was placed obliquely across the defect superficial to the fascia lata and wired in place to the left second rib above and the right fourth rib below. After placing bone chips on the surface of the fascia lata, the pectoral muscles were re-approximated in the midline where possible, and the skin and subcutaneous tissues were closed in layers (Figures 5, 6).

Postoperative Course

Postoperatively the patient maintained a satisfactory tidal volume and did not require assistance with her ventilation at any time. Except for temporary urinary retention, her

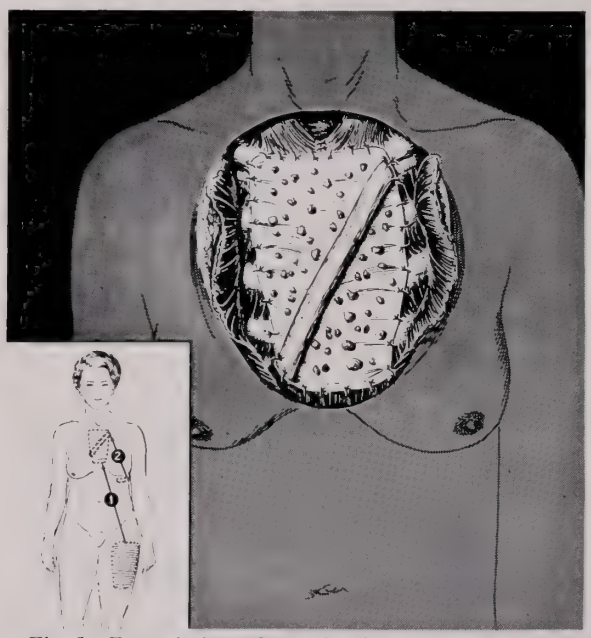

Fig. 5—Frontal view of completed reconstruction.

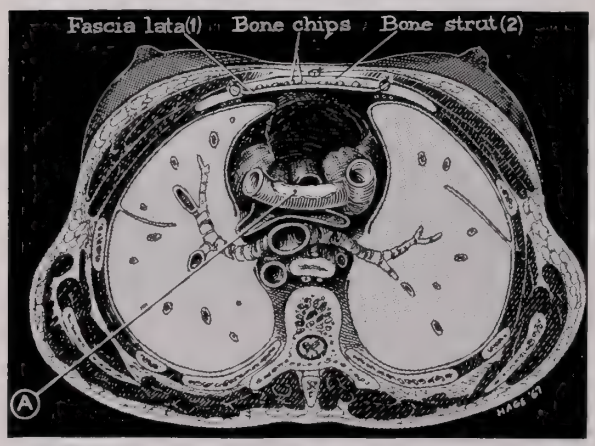

Fig. 6—Cross section illustrating chest wall reconstruction.

postoperative course was uncomplicated, and she was discharged from the hospital on December 16, 1966.

The patient remained in good health but was readmitted to the same hospital on April 3, 1967, for excisional biopsy of a very small nodule in the right breast. This proved to be an adenocarcinoma, and a right modified radical mastectomy was accomplished, sparing the pectoral muscles. The patient was discharged on the fifth postoperative day and has remained well since.

Comment

Most malignant sternal tumors grow relatively slowly and spread by local invasion. This characteristic makes aggressive en-bloc excision the only successful means of primary treatment feasible in the majority of cases. As in the case presented, chest wall reconstruction can be accomplished with relative ease, but it must be tailored to meet the individual requirements of a variety of large defects.

Summary

Primary chondrosarcomas of the sternum invade locally and should be treated by wide en-bloc resection. The extent of chest wall reconstruction depends upon the defect created, often requiring improvised techniques.

Acknowledgment

The authors wish to express deep appreciation to Dr. Thomas J. Kinsella for his advice in this case. His originally described technique of sternal reconstruction (2) was followed closely.

The Hourglass of Time

At least once to every man must come the sudden and disconcerting discovery that the corporate cells of his physical body are rapidly approaching insolvency. The sand is running low in the hourglass of time. And the option has already lapsed on a thousand youthful dreams which were never brought to pass.

A fortieth or a fiftieth birthday can be an ominous thing for the individual who takes time out to think. Youth has gone. The eagerness of anticipation is slowly giving way to mellow recollection. Youth rides in the cab of the locomotive and jubilantly surveys the track ahead. Age rides in the observation car and gazes back with sweet sorrow, upon the fading scenes of the past. And it requires a certain amount of readjustment.*

Derivatively Speaking

Migraine—from Greek hemi (half) plus kranion (skull)

He isn't burdened by his hypertension or his therapy...

Butiserpazide® lowers blood pressure so smoothly that patients are often untroubled by either the disease...or treatment

BUTISERPAZIDE provides not only the classic thiazide/reserpine formula; it supplements it with the mildly sedative effect of BUTISOL (butabarbital).

Clinical comparisons have shown that many patients respond to this treatment with (1) smooth, uniform lowering of blood pressure[1]... at times *below* the levels attained with previous therapy[2]; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness[2]; plus (3) "...lowered incidence of drug side effects."[2]

And BUTISERPAZIDE offers an added advantage: the usual dosage is just 1 tablet once or twice daily. It is available in two strengths for dosage flexibility. Are there any hypertensives in *your* practice who might find life a little pleasanter on BUTISERPAZIDE?

Contraindications: Sensitivity to any component, porphyria, peptic ulcer, ulcerative colitis, mental depression, renal impairment or shutdown. **Warnings:** Consider the possibility of sensitivity reactions in patients with history of allergy or bronchial asthma. Coated potassium tablets, sometimes administered in conjunction with antihypertensive therapy, may be associated with small bowel lesions, which have led to obstruction, hemorrhage and perforation. Surgery has frequently been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting, or g.i. bleeding occur. *Use in Pregnancy:* Exercise caution, since thiazides cross the placental barrier and may cause fetal or neonatal hyperbilirubinemia, thrombocytopenia or altered carbohydrate metabolism; adverse reactions seen in the adult may occur in the newborn. **Precautions:** ***Butisol*** (butabarbital)—Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression. ***Hydrochlorothiazide*** —May induce electrolyte imbalance; when used with digitalis or one of its glycosides and in patients with severe hepatic insufficiency, cardiac arrhythmias or symptoms of impending hepatic coma may occur. Discontinue and institute appropriate countermeasures if prolonged use produces hypokalemia or (likely only with sodium restriction) hyponatremia and hypochloremic alkalosis. (Ammonium chloride, used to reverse hypochloremic alkalosis, is contraindicated in hepatic disease.) May produce elevated serum uric acid levels (and, infrequently, gout) or reduce glucose tolerance, altering insulin requirements in diabetics. ***Reserpine*** —Observe for signs or symptoms of peptic ulcer or ulcerative colitis. Discontinue at first sign of mental depression; keep in mind possibility of suicide. Exercise extreme caution in history of mental depression. May produce cardiac arrhythmias when used with digitalis and quinidine, or may precipitate biliary colic in patients with gallstones. Discontinue 1 to 2 weeks before surgery; inform the anesthetist in event of emergency surgery. Exercise caution in history of epilepsy. Discontinue 1 to 2 weeks before ECT. ***General*** —Reduce concomitant antihypertensives by at least 50%, and exercise caution in coronary artery disease. **Adverse Reactions:** Dizziness, drowsiness, weakness, nasal congestion, leg cramps, nausea, palpitation, superficial skin bruises, headache, dehydration, skin rash, "hangover," systemic disturbances, diarrhea, itching, vomiting, paresthesia, photosensitivity, pancreatitis, jaundice, xanthopsia, purpura, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, anorexia, gastric irritation, abdominal cramping, constipation, glycosuria, vertigo, cutaneous vasculitis, orthostatic hypotension (potentiated by alcohol, barbiturates, or narcotics), increased salivation and gastric secretion, increased intestinal motility, loose stools, angina-like syndrome, arrhythmias, bradycardia, flushing, hypotension, nervousness, paradoxical anxiety, rarely atypical Parkinsonian syndrome, central nervous system sensitization (manifested by dull sensorium, deafness, glaucoma, uveitis, optic atrophy), dryness of mouth, syncope, epistaxis, weight gain, and impotence or decreased libido. **Usual Adult Dosage:** BUTISERPAZIDE®-25 or BUTISERPAZIDE®-50: 1 tablet daily or b.i.d. *Before prescribing or administering, see package insert.*

Grand Rounds

Systemic Mast-Cell Disease*

RICHARD R. STURGEON, M.D.
Medical Resident

TISSUE MAST cells were first described in 1877 during an investigation of the staining of fresh tissue by the new aniline dyes then being produced by the German chemical industry. Ehrlich observed that some connective tissue cells contain granules which stain metachromatically** with toluidine blue and other basic dyes. The cells were most numerous in areas of inflammation and near blood vessels. Ehrlich considered these cells to be overnourished connective tissue elements and called them "mast cells."

Mastocytosis, an abnormal proliferation of tissue mast cells, is being recognized with increasing frequency as a systemic disease. This disorder was originally described by Nettleship[1] in 1869 in its cutaneous manifestation, urticaria pigmentosa. Tourraine[2] first reported systemic involvement in 1933. It was not until 1949 that Ellis[3] reported autopsy findings which conclusively demonstrated generalized systemic involvement with infiltrations of skin, liver, bone, spleen, lymph nodes, pancreas and thymus.

An abnormal proliferation of mast cells was found in a patient at Hennepin County General Hospital and stimulated this discussion.

Case Report

The patient was a 71-year-old white male admitted because of an anorexia and weight loss. He was also noted to have rectal bleeding and recent onset of urinary incontinence.

Physical examination revealed a cachectic, dehydrated elderly male. His skin had petechial, non-pruritic, non-blanching brown lesions, maximal over his flanks. Cataracts were present. His abdomen was distended with active bowel sounds. An enema brought

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, November 21, 1967.

**See Test Your Word Score Page 649.

forth bloody mucus. Gastrointestinal workup was negative except for almost no free gastric acid, with persistent filling defect and lack of motility in the cardia of the stomach. Chest and bone x-rays were normal.

A laparotomy was performed and the stomach found to be normal. A slightly enlarged spleen was adherent to adjacent tissue and had many small white and dark nodules over its surface. The liver and the small and large bowel appeared normal. A large number of 1-2 cm. nodules were scattered throughout the mesentery.

On biopsy examination these were lymph nodes and revealed reticulum cell proliferation with increased eosinophils and mast cells. Although there was a difference of opinion, the consensus was that they represented mastocytosis. The bone marrow also demonstrated increased mast cells although peripheral blood was normal.

This patient did not have skin or bone manifestations of mast-cell disease and his scratch test was negative. He had no gastrointestinal symptoms suggesting increased amounts of histamine. In short, he probably had a lymphomatous disease with reactive mast-cell increases.

The patient died but no autopsy was obtained.

Nature of Mast Cells

The mast cell, as defined by Selye[4], is "a connective tissue element which possesses cytoplasmic granules that stain metachromatically under ordinary conditions." The most convincing evidence indicates that these cells arise from small wandering lymphocytes.

It has been shown that wandering lymphocytes take on metachromatic staining in areas of inflammation[5]. Lymphocytes can be stimulated to differentiate into mast cells in tissue culture.

These same authors discussed the relationship of mastocytosis to lymphomatous disease. They stained bone marrow for mast cells in 15 patients with chronic lymphocytic leukemia and found increased numbers of mast cells as well as increased numbers of small lymphocytes. They also noted that miliary tuberculosis and marrow invasion with carcinoma caused lymphocyte and mast-cell proliferation.

Mast cells are found wherever there is connective tissue and are most numerous near small blood vessels. They also accumulate in areas of chronic inflammation, although an infectious etiology has not been demonstrated. Mast cells have been found within a histiocytoma[6], in normal pineal and pituitary glands, and in brain infarcts in the hedgehog[7]. There is also a peculiar localized collection in the thalamus of hedgehogs.

Content of Mast Cells

The function of the mast cell has been inferred from its contents. It has been shown to contain albumin, glycoprotein, polysaccharides, phospholipids[8], mucopolysaccharides[8,9], histamine, possibly serotonin and various enzymes. Enzymes present are: acid and alkaline phosphatase, lipase, stable cytochromicoxidase[8], alkaline protease[9,11] and histadine decarboxylase;[10] but there is no glycogen[8]. The lack of glycogen suggests that the mast cell is a site of active metabolic processes.

Serotonin

Serotonin has been demonstrated to be present in human platelets and chromaffin tissue, but studies on serotonin content in mast cells has led only to confusion. Apparently, mast cells of rodents and dogs contain abundant serotonin, whereas human mast cells contain little or none.

In patients with symptomatic systemic mast-cell disease Ultman[12] has

shown that: (1) serum 5 hydroxytryptamine is too low to be measured; (2) 24-hour urine collections for 5-hydroxyindole acetic acid are within normal limits; (3) tissue levels are within normal limits; (4) tissue 5-hydroxytryptophane decarboxylase is less than in controls.

Occasional reports of elevated urine serotonin products can be explained by disruption of platelets (high serotinin content) secondary to histamine release[13].

Heparin

Heparin has been reported to be the substance which in granules takes metachromatic stain. The mucopolysaccharide in mast cells has been shown to be 80-100% heparin[9], closely related to hyaluronic acid. Mucopolysaccharides isolated from mast-cell neoplasia are heterogeneous, a chondroitin sulfate-like compound[9]. An abnormal mucopolysaccharide has been found in the urine of patients with systemic mast-cell disease[12]. This is apparently unique to this disorder and is a heparitin sulfate. It has no anticoagulant activity and no hyaluronic acid moiety.

It is presumed that heparin liberated from mast cells has little or no local anticoagulant effect and presumably is removed via lymph channels. Also granules (which stain for mucopolysaccharides) are phagocytozed by nearby connective tissue cells, fibroblasts and inflammatory macrophages, and are digested promptly.

Histamine

The presence of histamine is well documented. Riley[8] has shown that tissues containing many mast cells are rich in histamine and vice versa. The injection of "48/80," a potent histamine liberator in the rat, caused not only release of tissue histamine but disruption of mast cells. Certain pathological tissues are extremely rich in histamine and mast cells, e.g., mastocytoma. It is noted that certain fetal tissue is devoid of mast cells and histamine. However, this same tissue in adult animals is rich in both.

Blood levels of histamine in systemic mast-cell disease have been measured and found to be 4.0 ugm/ml, compared to a normal of 0.02-0.08 ugm/ml. Histamine content of spleen was 30 times normal[12]. Spleen and skin homogenates contained increased levels of histadine decarboxylase as well as increased histamine[10]. Transient histaminuria reflects transient histamine release in most diseases. The level in urine is proportional to the blood level. This may be correlated with symptoms as well, but mastocytosis does exist without histaminuria.

The histadine decarboxylase previously mentioned has been found to be five times normal in a spleen invaded with mast cells[13].

The histamine metabolism in systemic mast-cell disease has been studied in an effort to detect a possible metabolic defect.[10] Carbon[14]-labeled histadine injected had a normal disappearance rate; likewise, C-14-labeled histamine was metabolized at a normal rate, negating a degradation block. The most likely possibility is that histamine excess results from simple overproduction of histamine by increased numbers of cells.

What then is the normal function of this cell? Riley[15] has shown that an inflammatory reaction creates an increase in tissue mast cells. He painted the skin of mice with known carcinogen initiators. The inflammatory reac-

tion and dysplastic epidermis was bordered by a layer of mast cells, a response which persisted until dysplastic cells underwent malignant change, at which time the mast-cell response no longer occurred.

Histamine appears to stimulate phagocyte capacity of the reticuloendothelial system and "activates" loose mesenchymal cells.

Mast-Cell Cycle

These phenomena have lead Riley to propose the "Mast Cell Cycle" theory. Trauma and/or acute inflammation causes rupture of mast cells. Fast-acting histamine causes vasodilation and increased permeability with concomitant increase in plasma colloid exudation. Histamine activates connective tissue cells which phagocytose colloids and heparin. Heparin is closely related to hyaluromic acid and these cells are now "full" and primed for metabolic needs in preparing mucopolysaccharides of their own to lay down ground substance.

Function of Mast Cells

Detoxification

This theory has had some doubt shed upon it by the observations of Chayen.[16] Mast cells in tissue culture were noted to swell and become visible in response to histamine. Continued exposure to histamine causes the mast cell to burst, which suggests a detoxification function.

Further findings relate mast cells to the process of necrosis.[17] Mast cells in a test system appeared to have the capacity to increase tissue resistance to necrotizing agents.

Protection by Heparin

It is known that heparin inhibits both normal and malignant cell growth in tissue culture.[5] It has also been shown that rat tumor grows faster in subcutaneous implants if the animal is depleted of mast cells with 48/80.[18] This loss of "protection" was not corrected with histamine, heparin or serotonin. It is interesting to speculate on this potential role of mast cells.

Heparin has known antithromboplastin and antithrombin activity; it also functions in chylomicra* dissolution and fat transport. Swank and Levy[19] injected heparin in dogs and found decreased circulating chylomicra and apparently enhanced chylomicra transport through capillary walls. Bragden[20] showed that antiheparin compounds increased serum lipids.

Change During Hibernation

Evidence is available that mast-cell function is under general body regulation.[5] Hibernating animals are noted to have both increased mast cells and increased clotting times. Thyroid-stimulating hormone is known to increase the number of mast cells, while thyroid hormone has an opposite effect. Both adrenocorticotropin polypeptide and cortisone decrease mast cells and conglomerate their granules.

Clinical Features

Skin

The most obvious lesion in systemic mast-cell disease is urticaria pigmentosa: a dermal infiltration with mast cells, producing red-brown discrete macules mainly over the trunk. The lesions may have a waxy appearance,

*See Test Your Word Score Page 649.

usually persist indefinitely, and are non-pruritic unless they urticate. Urtication is produced by even minor trauma. Two thirds of patients will demonstrate dermatographism.*

The onset of urticaria pigmentosa in childhood has a different prognosis from that of adult onset. Of 28 cases, four have cleared (three in childhood), seven to eight have improved, and the rest are unchanged.[21] Another series[22] of 26 cases in children reported that six cleared, fourteen improved, and two remain unchanged. Generally, cases acquired in late childhood or early adulthood tend to persist.

Mast-cell proliferation can occasionally occur as an isolated lesion, i.e., as mastocytoma, usually 3-4 cm in size.[23]

Systemic Manifestations

Of persistent cases of urticaria pigmentosa, Caplan[2] reports that 15-30% at some time have systemic involvement, and of these lesions, one third become malignant.[23] It is of interest that visceral manifestations of systemic mast-cell disease usually post-date the onset of skin lesions by many years. Enlargement of spleen, liver, and lymph nodes represents early evidence of widespread mast-cell proliferation in the reticuloendothelial system.

The physiologic effects of excess histamine are quite evident in the clinical expression of this disease. Facial flushing, pruritis, tachycardia, headache, malaise, and dermatographism are common. Histamine stimulation of the gastrointestinal tract causes nausea, vomiting, cramps, diarrhea, and peptic ulceration. Acute histamine reactions can be precipitated by exposure to cold, trauma, radiation, infections, alcohol, and/or alkaloids. Some problem in differentiation from carcinoid exists. Generally, carcinoid causes more lower than upper gastrointestinal symptoms. There is more respiratory involvement, i.e., bronchospasm, and it produces an erythema with cyanosis, as contrasted to the bright red flush of histamine.

Visceral Involvement

As viscera become involved, many symptom complexes occur. Migratory bone pain is not uncommon, as bone can be invaded anywhere. Radiologic findings are extremely variable; increased or decreased bone density, increased trabeculations, bone islands, and/or periosteal thickening have all been reported.[25]

Hepatomegaly, splenomegaly, and lymph-node enlargement have been mentioned and reflect mast-cell proliferation. A hematologic dissemination may occur, i.e., mast-cell leukemia,[26] though mast-cell leukemia has been reported without the clinical picture of mast-cell disease.[7] Almost always, however, cutaneous manifestations are present.

Gastrointestinal involvement is reflected by pain, nausea, vomiting, flatulence, and diarrhea. These effects, at least initially, are secondary to histamine and are related to cutaneous flareups. Strangely enough, the expected increase in gastric acidity has not been demonstrated.[22] The reason for this remains unexplained.

Steatorrhea has only rarely been reported. A group from Copenhagen[28] reported steatorrhea and hypocalcemia. They also noted normal villous architecture and crypts on small-bowel biopsy. Mast cells were present in the lamina propria and muscularis. Liver biopsy was normal. On the other hand, a report from South Africa[29] revealed similar steatorrhea and hypo-

*See Test Your Word Score Page 649.

calcemia (even tetany), but jejunal and ileal biopsy demonstrated short, blunt villi. A marked infiltrate with eosinophils was present in the submucosa, with deeper mast cells and inflammatory cells. The blunted villi were presumed to be secondary to eosinophil infiltrate. It has been shown that histamine is chemotoxic to eosinophils and that continued or intermittent exposure can cause an eosinophil response. This patient responded clinically to steroids.

Bleeding Diathesis

A bleeding diathesis is occasionally reported. Efforts to demonstrate increased levels of heparin have been of no avail.

Anemia is often present, and mast cells are abundant in the marrow.

Mast cells are also found in bone, and patients may have low serum calcium and elevated alkaline phosphatase.

Therapy

Isolated reports of brief remissions utilizing steroids exist, as in the case reported from South Africa.[29] However, no case of bona-fide systemic mast-cell disease with tissue diagnosis has shown a prolonged response to steroids.

Occasionally antihistamines will afford some symptomatic relief, but reports of improvement in diarrhea and pruritis are the only consistent findings. The specific anti-serotinin preparation, Periactin, is no better than antihistamines.

Summary

In summary, systemic mast-cell disease usually presents as long-standing urticaria pigmentosa, typically with dermatographism. Migratory bone pain and symptoms of histamine release occur. Gastrointestinal symptoms range from nausea and cramps to steatorrhea. Hepatosplenomegaly and lymph-node enlargement are present, and weight loss may be evident.

Laboratory studies reveal pancytopenia, and occasionally low serum calcium and elevated alkaline phosphatase. Fecal fat may be elevated. Bone lesions may appear.

Though many patients of urticaria pigmentosa go through life without difficulty, when symptoms such as the above appear further studies are indicated. Diagnosis can be made only by tissue examination. Skin, marrow, and lymph-node involvement can be detected with special stains. The pathologist should be forewarned, as mast cells may not be obvious on routine stains.

Smoking—A Compulsion Neurosis?

Tens of millions of persons smoke. And tens of millions will tell you that they're not men enough, or women enough, to quit. And so, by a process of mathematics, we must accept it as reasonably normal.

If there were only a few thousand smokers unable to quit, then we would call it a compulsive neurosis. By its very nature, a neurosis must be a minority report on the subject of human behavior.*

If fifty million people say a foolish thing, it is still a foolish thing.—Anatole France

He that is good for making excuses is seldom good for anything else.—Benjamin Franklin

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl®-1.

(norethindrone 1mg. & mestranol 0.05mg.)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of NORINYL-1 (norethindrone 1 mg. with mestranol 0.05 mg.) in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with NORINYL-1. Therefore, if such tests are abnormal in a patient taking NORINYL-1 it is recommended that they be repeated after the drug has been withdrawn for two months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibromyomata may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. 5. NORINYL-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, and as in all cases of irregular bleeding *per vaginam*, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged NORINYL-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving NORINYL-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. 11. Because of the effects of estrogens on epiphyseal closure, NORINYL-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with NORINYL-1 may mask the onset of the climacteric. 13. The pathologist should be advised of NORINYL-1 therapy when relevant specimens are submitted.

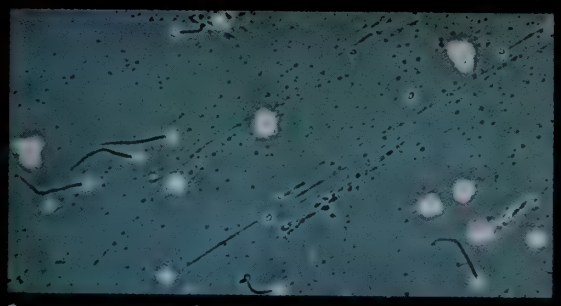
Side effects observed in patients receiving oral contraceptives: The following adverse reactions have been observed in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretion, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression.

Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation post-treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption, itching.

The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has been neither established nor disproved): thrombophlebitis, pulmonary embolism, neuro-ocular lesions.

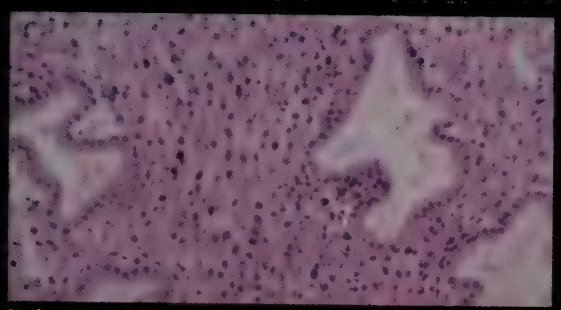
The following laboratory results may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, Factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from
SYNTEX
LABORATORIES INC., PALO ALTO, CALIF.



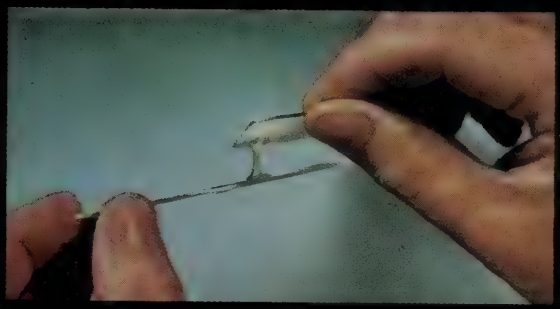
Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation. These effects are illustrated below.

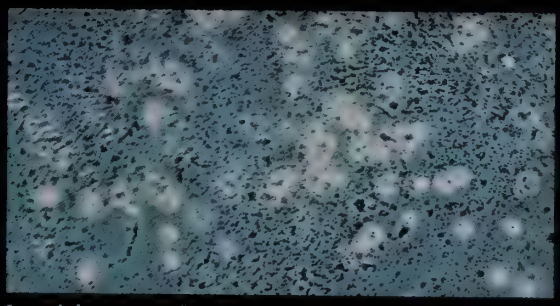


Untreated Patient

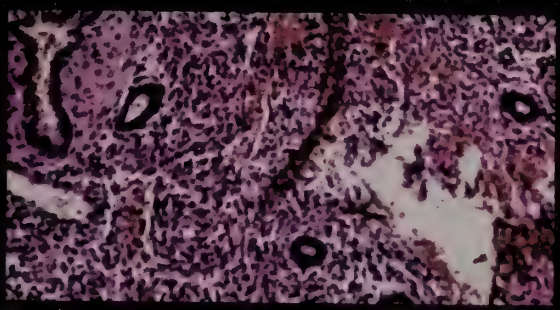
Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.



Spermatozoa appear healthy, active, freemoving.



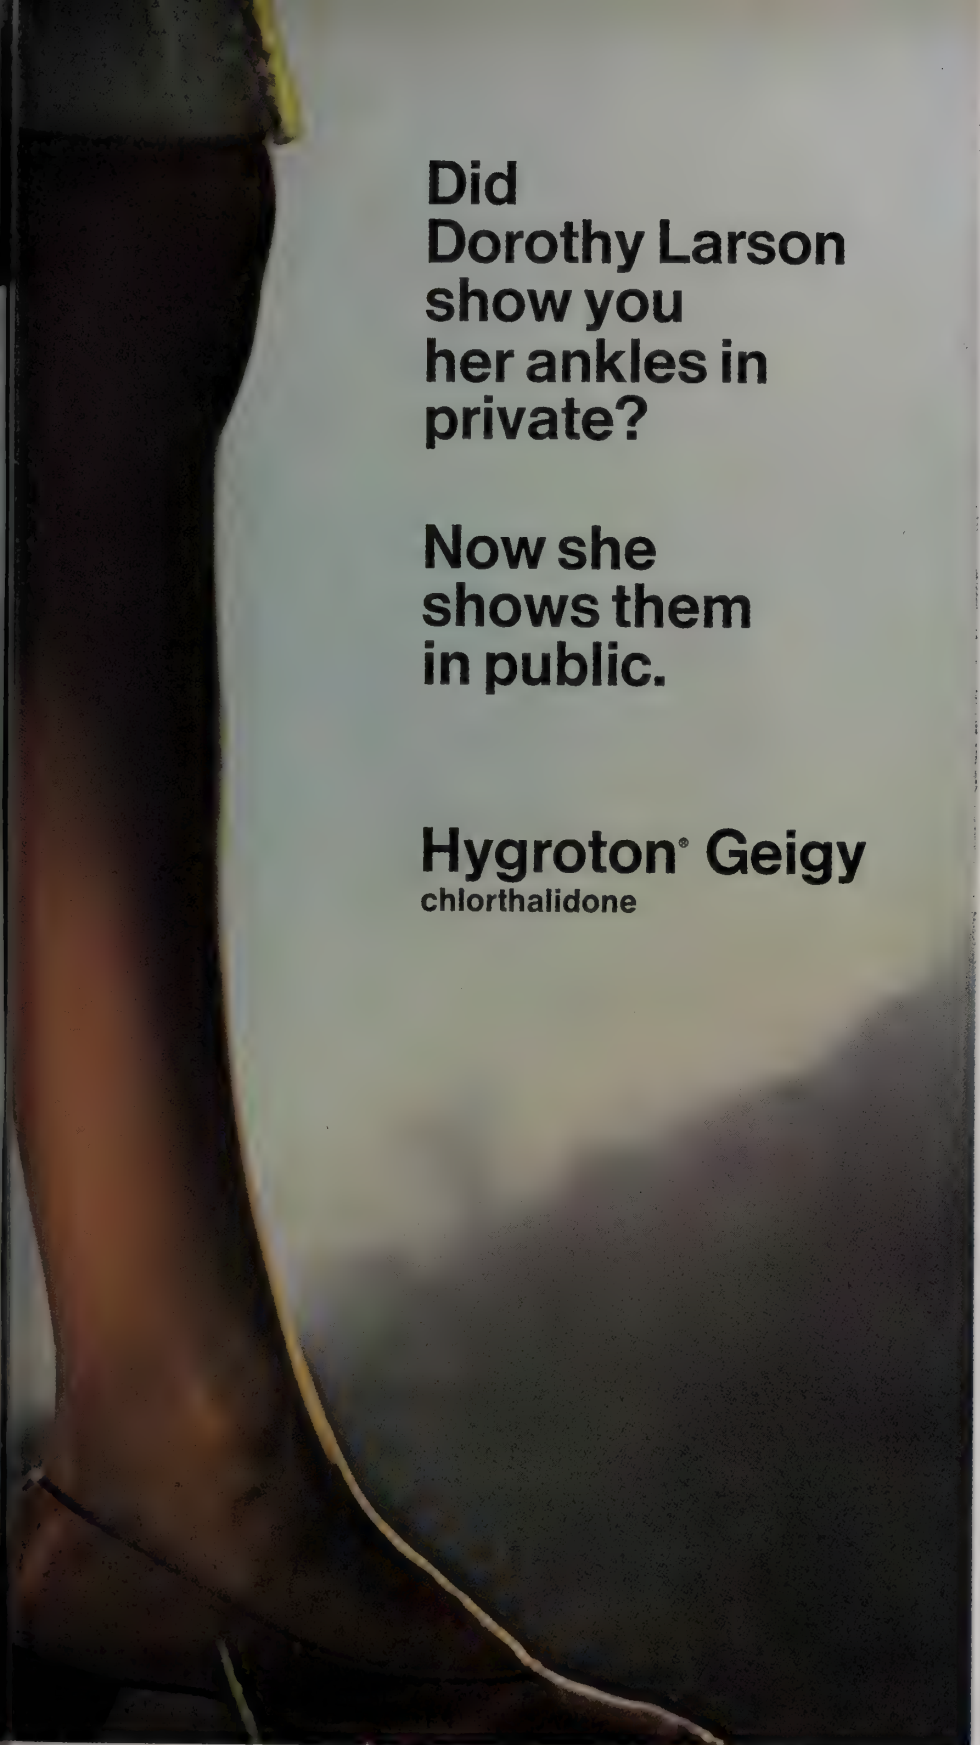
Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.



Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.



Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl®-1 tablets
(norethindrone 1mg. & mestranol 0.05mg.)

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

Indications: Hypertension and many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Use with caution in pregnant patients, since the drug may cross the placental barrier and adverse reactions which may occur in the adult (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential problems in the newborn.
Precautions: Antihypertensive therapy with Hygroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents or other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Barbiturates, narcotics or alcohol may potentiate hypotension. Be- cause of the possibility of progr sion of renal damage, periodic determination of the BUN is indi cated. Discontinue if the BUN ris or liver dysfunction is aggravate Hepatic coma may be precipitat Electrolyte imbalance, sodium a or potassium depletion may occ If potassium depletion should oc cur during therapy, Hygroton sh be discontinued and potassium supplements given, provided the

Did Dorothy Larson show you her ankles in private?

Now she shows them in public.

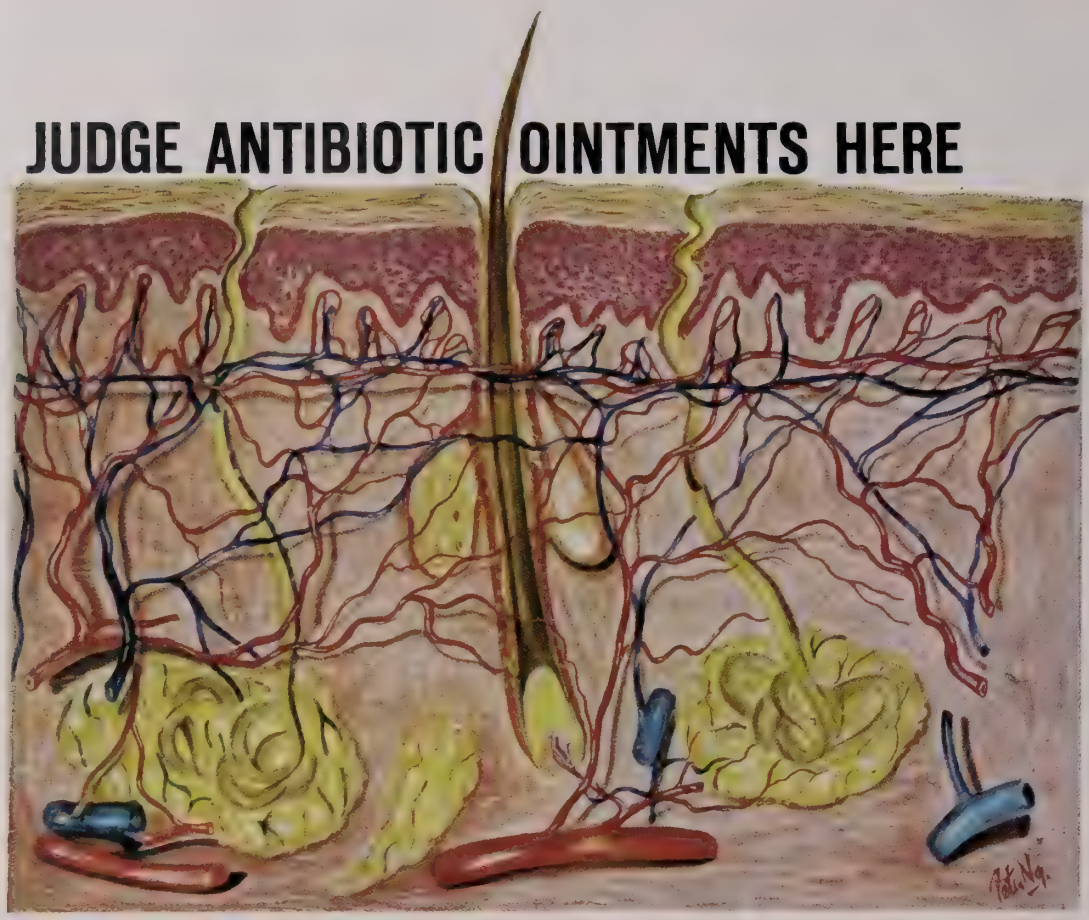
Hygroton® Geigy
chlorthalidone

Your office examination confirmed Mrs. Larson's ankle edema.

You prescribed Hygroton to get rid of the edema.

And you found that Hygroton is not only usually effective; it frequently costs less than other equivalent therapy.

A nice way to treat the Mrs. Larsons in your practice.



Hygroton therapy may mean troublesome side effects for some patients. And you can't prescribe it for patients with hypersensitivity to the drug or severe renal or hepatic diseases. Before writing it for your patients, please check the prescribing information. It's summarized below.

tient does not have marked oliguria.
ke special care in cirrhosis or vere ischemic heart disease and patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
verse Reactions: Nausea, gastric tation, vomiting, anorexia, constipation and cramping, dizziness, akness, restlessness, hyperglycemia, hyperuricemia, headache, scle cramps, orthostatic hypotension, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.
Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.
Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

Clinical Path Conference

A Fetal Complication with Maternal Diabetes

Case History

Dr. Robert L. Strom:*

A 2930-gram male infant was born to a 22-year-old Caucasian primagravida whose pregnancy was complicated by preeclampsia, polyhydramnios and diabetes mellitus. The first stage of labor lasted six hours and forty-five minutes; the second stage, thirty minutes; and the third stage, five minutes. Medication during labor consisted of Largon 20 mg. i.m.; the anesthesia was 1% xylocaine by local infiltration. The placenta appeared normal and three vessels were present in the edematous umbilical cord. Upon delivery, no heart beat or spontaneous respirations were noted. The child was suctioned, intubated, and given 0.1 cc. of 1:1000 epinephrine and 10 cc. of sodium bicarbonate by intracardiac injection. A good heart beat was obtained after eight minutes, and spontaneous gasps began at ninety minutes. After three hours, respirations were normal but muscle tone remained flaccid.

The cord blood type was A negative. The cord hemoglobin was 14.4 grams % with 12,100 white blood cells per cu. mm. and 75 nucleated red blood cells. The initial cord blood sugar was 310 mg.%. Two hours later the infant's blood sugar was 57 mg.%. An intravenous infusion of 10% dextrose in water was initiated. Cord blood electrolytes were: sodium 122, mEq/L, potassium 5.8 mEq/L, chloride 87 mEq/L, CO_2 18 mEq/L, and calcium 10 mg.%. A urine specimen showed a pH of 5.5, and an albumin of 2+ with no sugar or acetone. Microscopic examination of the urinary sediment revealed occasional granular casts and one to two white blood cells per high-powered field.

The rectal temperature was 98°F., the pulse was 144 per minute, and the respirations were 32 per minute. The skin revealed multiple ecchymoses with facial petechiae. The anterior fontanel was 1 × 1 cm. and the head was moderately molded. The color was mottled with cyanosis of the distal parts. Auscultation of the lungs revealed a few rales over the right upper lobe with no retractions and good air exchange. The heart tones were normal. In the right abdomen a firm smooth mass was palpated extending from the costal margin downward to the pelvic rim, not crossing the midline. The liver was palpable 1 cm. below the right costal margin. Neurological examination revealed generally poor muscle tone and no Moro reflex. A chest x-ray, a flat film of the abdomen, and an intravenous pyelogram were performed. The child suffered a cardiorespiratory arrest 13 hours after birth and expired.

Clinical Discussion

Dr. Roger Herdman:*

This male infant was born to a young white primagravida who had several complications of pregnancy including preeclampsia, diabetes, and polyhydramnios, all of which I think have some bearing on the ultimate clinical course of her child. There is no mention in the protocol of whether the

*Associate Pathologist, Hennepin County General Hospital.
**Assistant Professor of Pediatrics, University of Minnesota.

baby was full term. However, since the birth weight was somewhat low for a diabetic mother, I shall assume that the baby was somewhat premature and may have had some intrauterine dwarfing. The presence of three cord vessels was presumably reported since it is well known that if there is only one umbilical artery, the incidence of anomalies in the child is much higher. The delivery itself sounds normal; however, the child was essentially dead and, after being resuscitated, was never neurologically normal.

As the mother's blood type is not stated in the protocol the possibility of ABO incompatibility cannot be commented upon. The cord hemoglobin was a little low and nucleated red blood cells were seen, as is commonly the case in babies of diabetic mothers. The cord electrolytes were somewhat abnormal, and I would interpret this set of chemical values as indicating that the mother was having some difficulty with the control of her diabetes at the time of delivery. A few hours later the child's blood sugar was a normal 57 mg.%. On the basis of recent data, blood sugar determinations in newborns mirror very poorly the actual blood sugar levels, since the cord blood sugars when monitored continuously may vary as much as 20 to 30 mg.% over a one- or two-minute period.

I would like to say a word here about the use of resuscitative electrolyte solutions in newborns. I do not think fluid management was a problem here, since this baby was given about 20 milliosmols over a four-hour period. The use of concentrated sugar solutions to resuscitate infants may lead to an increased total osmolar load. Hence it is recommended that no more than 25 milliosmols per kilo body water be given over a four-hour period.

The electrolyte situation seemed to improve and a very scanty urine specimen was obtained, which showed 2+ albumin and very little else. Newborns are allowed to put out about 250 mg. of protein per square meter; however, I think the 2+ albuminuria should be considered an abnormality and a valuable diagnostic clue to what was going on in this child.

The ecchymoses and petechiae seen on the baby could have been associated with the delivery, since petechiae on babies' faces are frequent with vaginal deliveries. However, in this child's particular circumstances, the petechiae may have been an expression of a bleeding tendency. An alternative explanation for the petechiae may have been thrombocytopenia due to sequestration of platelets into a large hemorrhagic area in the body cavity. The presence of acidosis is known to increase the bleeding tendency. Systemic defibrination may have occurred with circulating fibrin degradation products acting as antithrombins.

Then we have mention of the very large mass in the right side of the abdomen, with the lower edge of the liver apparently palpated above the mass. After a limited number of x-ray studies, the child expired. I think at this time it would be appropriate to view the x-ray films.

Radiologic Findings

Dr. Oscar Lipschultz:*

A number of these films were taken in an attempt to demonstrate the kidneys and the lower urinary tract. On the flat plate of the abdomen (Figure 1) air was seen in the small bowel, but the significance of this finding is open to question in a newborn infant. I get the impression that there is some increased density to the right of the midline in the area of

*Attending physician, Department of Radiology, Hennepin County General Hospital.

the mass. I cannot adequately define the limits of the mass but we do not see the renal outline. I doubt very much that the mass is the liver since it is circumscribed in a manner that I would not associate with hepatic masses. On the intravenous pyelogram study, the kidneys did not function, and I wonder whether perhaps the administered dosage was not large enough to visualize them. Then we have a film of the chest which shows the cardiac size to be at the upper limit of normal. The vascular markings in the lung fields do not suggest a shunt at the cardiac level. I do not get the impression that the lungs show the nodularity that you would associate with atelectasis of the newborn or hyaline membrane disease.

I am of the opinion that this youngster was premature since I do not see the epiphysis for the distal femur on either side.

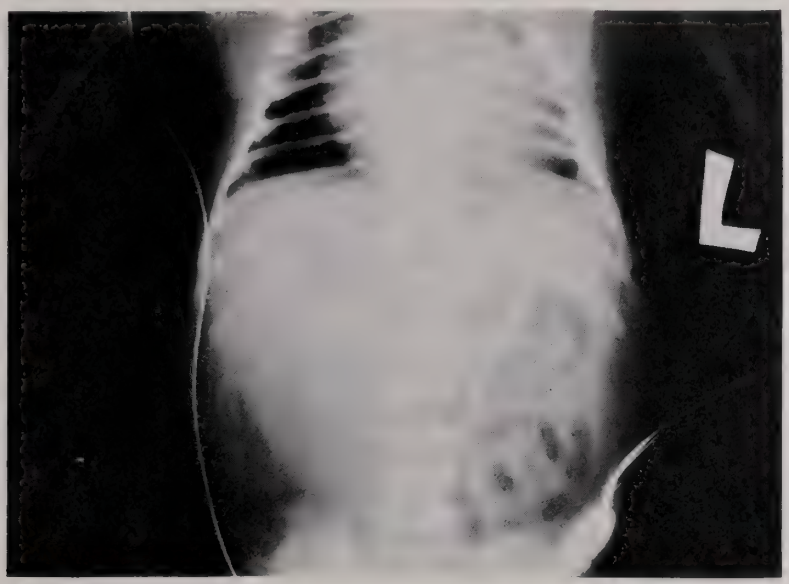

Fig. 1—Flat plate of the abdomen and chest x-ray: A mass density in the right abdomen displaces the small bowel gas pattern to the left abdomen.

Discussion

Dr. Herdman:

I am going to assume that the intravenous pyelogram was done correctly, that there was no visualization of the urinary tract, and that the chest film is within normal limits. I think there are two problems of interest here. First, what is the nature of the mass and why are the kidneys not functioning? And second, what caused the child's demise? I am going to attack the problem of the differential diagnosis of abdominal masses in newborns initially.

Abdominal Hematomas

Hematomas do occur in newborns, particularly involving the liver, spleen, or retroperitoneal space. However, I do not think that this consideration is germane since an abdominal hematoma does not explain the absence of kidney function. The mass was on the opposite side from the spleen and was well localized, with nothing to suggest that it was retroperitoneal.

Renal Abscess

Another consideration might be a renal or perinephric abscess. I would

exclude this also since there were no particular signs of infection, such as high fever or leucocytosis. The cord was described as edematous but did not appear infected, and there were no other portals of entry for infection.

Abdominal Tumors

Tumors represent a logical explanation for an abdominal mass in infancy. The prime possibilities are retroperitoneal lymphangiomas, teratomas, retroperitoneal hemangiomas, neonatal Wilms's tumors,* or neuroblastomas. With the exception of neuroblastoma, Wilms's tumor and possibly teratoma, these do not fully explain the absence of renal function bilaterally. The presence of an abdominal tumor does not really explain why this child was so ill. It is convenient to assume that the mass and the illness were related, although this is not necessarily true. Since the child was premature and was born of a diabetic mother with associated complications, his demise does not necessarily have to be related to the abdominal mass. At any rate, if the child did have a renal tumor, I believe the collecting system should visualize to some extent. If this was an adrenal hemorrhage, one might expect that the intravenous pyelogram would also visualize.

Polycystic or Multicystic Kidneys

I think that there are two other disease entities which commonly give rise to renal masses in children. The first is polycystic or multicystic kidney. A cystic kidney in the abdomen of an infant either does or does not function. If it functions, it is usually classified loosely as a polycystic kidney; if it does not function, it is generally termed a multicystic kidney. Multicystic kidneys are important mainly because they tend to be unilateral. If they are bilateral the child has no functioning renal tissue; if they are unilateral, the urinary drainage system is frequently anomalous. There is a possibility that this child had a multicystic kidney on the right and obstructive uropathy with nonfunction on the left. This would explain the bilateral nonvisualization on intravenous pyelogram and the morbidity of the child. However, if this were the case, one would expect to palpate the obstructed hydronephrotic kidney on the left. Another factor to be considered is the character of the right-sided abdominal mass. If it were a multicystic kidney, it should have been lumpy and uneven to palpation. Therefore, I am not too strongly attached to the diagnosis of cystic disease of the kidneys.

Obstructive Uropathy

Another common cause of renal masses in children is obstructive uropathy. Here again, in order to have nonvisualization of both kidneys, the obstruction would have to be bilateral; it would be quite unusual to have one kidney so massively enlarged and the other completely normal. It would also be difficult to explain the child's sudden demise. After all, he did not die of uremia. It would be impossible to die of uremia after being on dialysis in utero 12 hours before.

Renal Vein Thrombosis

Now I will proceed to discuss the entity I think the child had. I believe that this is a classic case of renal vein thrombosis. It is going to be difficult,

*See Test Your Word Score Page 649.

however, to predict whether the adrenals were involved and exactly what caused the rapid demise.

Why are infants of diabetic mothers so prone to thrombosis? This child was dehydrated at birth; in fact, most infants of diabetic mothers are dehydrated. They may be heavy, but that is due to excessive fat. Their total body water is low. This may be the reason that they are predisposed to thromboses in general, and to renal vein thrombosis in particular. Such infants have roughly 15 to 20 times the incidence of thromboses in general, and the renal vein heads the list as a site of thrombosis, with the adrenal vein not far behind. Many of these thromboses in infants of diabetic mothers occur in utero, are of some duration at birth, and show different thrombus morphology from that of other infants dying of thromboses. Infants of diabetic mothers with renal vein thrombosis tend to die very early as opposed to children of nondiabetic mothers. Another valuable clue here is the fact that this child was born of a mother with toxemia and polyhydramnios, which in children of diabetic mothers are common predisposing factors to renal vein thrombosis. In infants of nondiabetic mothers, sepsis, postoperative complications, and diarrhea are much more common causes of thromboses.

I want to take a few minutes to talk about renal vein thrombosis in general. Infants under two months of age represent a high-risk group for development of this complication, although there is a significant incidence of renal vein thrombosis after the first few weeks of life. It is interesting to speculate on why the clinical symptomology of renal vein thrombosis is so varied, extending from total anuria to complete recovery even in cases of bilateral thrombosis. Some children develop the nephrotic syndrome. I think that the anatomic sites of thrombosis and the speed with which they are occluded hold a valuable clue to the ultimate prognosis of this disease. This particular child, judging from the massive swelling of the kidney, the toxicity, and the sudden demise must have rapidly infarcted the total kidney. This is not necessarily the case in other instances, however, where, even if there is bilateral involvement, there may be spontaneous recovery. The degree of recovery relates to the amount of collateral venous circulation that remains patent.

Adrenal Vein Thrombosis

The adrenals are not infrequently involved and I think this may be a possibility. There is an interesting case in the literature where the adrenal was involved, and from the histology of the adrenal gland, which was fossilized at a certain stage of development, the time of the infarction could be accurately estimated. There is nothing in the protocol here that indicates whether adrenal involvement was present or not.

Operative Management of Renal Vein Thrombosis

The next question one might ask is: Should anything have been done for this child? I think not. Although most people recommend nephrectomy, which may result in a rapid recovery, there is body of opinion that suggests only medical observation. In view of this child's borderline clinical status, I believe he falls into the group of patients which should not be operated.

Intracranial Hemorrhage

Is there anything else which could explain this child's acute demise? I

mention this for completeness although there is no evidence in the protocol other than the depressed neurologic state. Very frequently these children have intracranial hemorrhage, although I think the renal complications alone would have been sufficient to cause this child's demise.

Clinical Diagnoses: 1. Renal vein thrombosis
2. Intracranial hemorrhage

Pathology

Dr. Strom:

On postmortem examination the baby had a few petechiae and ecchymoses over the head, face and scalp suggesting minimal birth trauma. The heart appeared to be slightly enlarged since it weighed 25 grams, and we would have estimated that the heart in a baby this size should weigh about 18 grams. There was a small patent ductus which probably caused no physiologic embarrassment.

Neonatal Atelectasis and Hyaline Membrane Disease

The lungs weighed 30 grams each and did not float when we placed them in water. There appeared to be some neonatal atelectasis of the lungs. A small amount of scattered hyaline membrane disease was present although the degree did not suggest that respiratory distress syndrome was a major component of this child's illness. Some polymorphonuclear leucocytes and round cells were present in the alveolar spaces suggesting early bronchopneumonia.

The liver weighed 125 grams and was somewhat enlarged. Between the liver cords we observed a significant amount of extramedullary hematopoiesis. This is seen in erythroblastosis fetalis, but also in prematurity alone without isosensitization. The spleen also showed some extramedullary hematopoiesis with proliferation of nucleated red blood cells.

Islet Cell Hyperplasia

The pancreas revealed increased numbers of islets of Langerhans, a closer view of which suggests that there was some islet cell hyperplasia (Figure 2). Islet cell hyperplasia does occur in infants of diabetic mothers in that the fetus attempts to supply the maternal needs for insulin. Hypoglycemia is not uncommonly seen in these infants after birth; however, this did not present a clinical problem in this case.

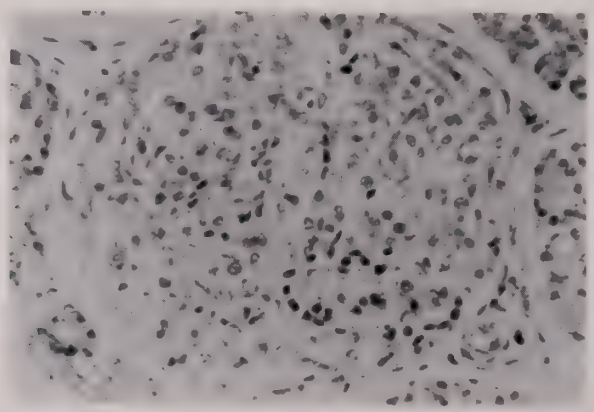

Fig. 2—Islet cell hyperplasia 45×.

Renal Vein Thrombosis

The abdominal mass was indeed a right kidney involved by hemorrhagic infarction; an in-situ photograph appears in Figure 3. The right kidney was significantly enlarged and there appeared to be some infarction of the right adrenal gland as well. The left kidney appeared uninvolved and very likely

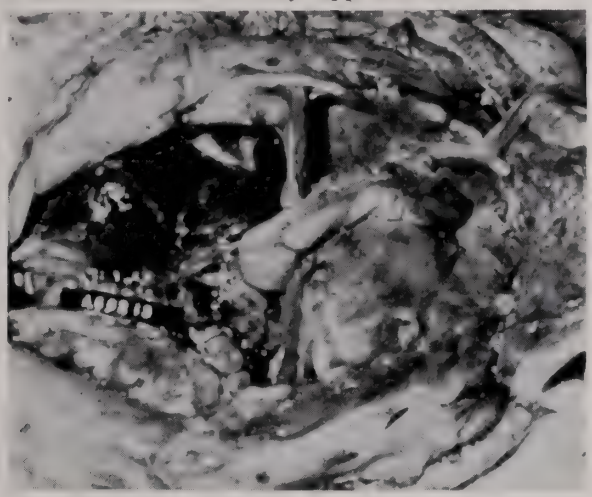

Fig. 3—Abdominal cavity opened to reveal the hemorrhagic infarction of the right kidney and adrenal at the top of the field.

put out a small amount of urine. I have no explanation for why it did not visualize on the intravenous pyelogram. The left adrenal did not appear to be significantly involved. The microscopic appearance of the kidney was that of hemorrhagic infarction; the thrombosed renal vein at the hilus is seen in Figure 4. Thrombosis was present in all radicles of the renal vein with early organization at the periphery. There was no evidence of recanalization. However, about the margin of some of the clots definite calcification could be seen. The calcium would suggest that the renal vein thrombosis was of some duration and probably occurred in utero. The left kidney was histologically normal and probably in good functional order.

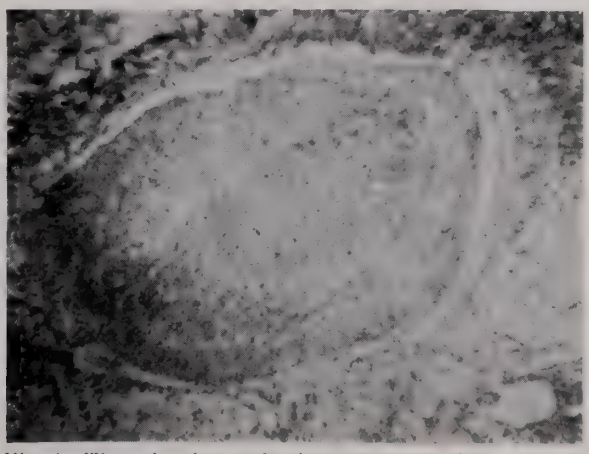

Fig. 4—Thrombus in renal vein at the hilus 45×.

The right adrenal gland was approximately 50% involved with hemorrhagic infarction. There was only a tiny focus of infarction in the left adrenal. The adrenal glands are sometimes involved with thrombosis of the adrenal veins, leading to a syndrome characterized by a very rapid respiratory rate and sudden death.

A few additional comments about renal vein thrombosis. In the large series reported by Abeshouse[1] there were 228 cases, 98 of which occurred in the first year of life. A total of 121 cases were unilateral: 57 on the left and 37 on the right.

Apparently the left kidney has a higher incidence of renal vein thrombosis, the highest incidence occurring early in life with approximately 50 to 60% of the cases appearing or being recognized in the first two months of life. There are several theories about why renal vein thrombosis occurs in these infants. One theory incriminates hydration, low fetal blood pressure, or birth trauma. Septicemia is incriminated in the older age group as well. In addition, in older infants there is an association between renal vein thrombosis and massive diarrhea, vomiting and dehydration. This is a well recognized entity and may be associated with fever and leucocytosis. Sometimes it is difficult to determine whether the diarrhea is initiated by the occurrence of renal vein thrombosis or whether the renal vein thrombosis is caused by the dehydration secondary to the diarrhea.

When Avery[2] called attention to the association between renal vein thrombosis and maternal diabetes in 1957 there were only four cases in the literature. Many more cases have since been recognized and treated surgically. There was thrombocytopenia in one of Avery's cases, and I note that we do not have a platelet count in this child. We do know that platelets are consumed with massive tissue infarctions, and the thrombocytopenia may be a clue to the presence of infarcted renal tissue. Minimal intracranial hemorrhage was present in the posterior fossa and over the cerebral convolutions.

Pathological diagnoses:
1. Right renal vein thrombosis with hemorrhagic infarction of the right kidney.
2. Focal infarction of right adrenal gland.
3. Neonatal atelectasis and mild hyaline membrane disease.
4. Intracranial hemorrhage.
5. Hyperplasia of the islets of Langerhans.

A Surgical Resident:

I was a little surprised when you said that nothing could be done for this child. Say the infant had lived for 24 hours, assuming you based your diagnosis mainly on history and the maternal diabetes, would you say that he should have been taken up to surgery for removal of the abdominal mass?

Dr. Herdman:

Certainly. There are similar case reports in the literature of children who did very well following surgical removal of the involved kidney. If you can bring yourself to operate on a child in such poor condition, there is a good chance that removal of the mass will decrease the toxicity.

the complaining earache... key to serous otitis media

Robert H. Lofgren, M.D.
Associate Surgeon, Massachusetts Eye and Ear Infirmary, Boston, Massachusetts

Serous otitis media is probably the most common ear problem in children, especially in the wintertime. Diagnosis is usually easy in adults, but may be quite difficult in children, especially the very young child where one has to depend almost entirely on the physical findings.

The symptoms of serous otitis are a fullness in the ear, a mild hearing loss and mild earache. The earache can best be described as a "complaining earache" instead of a "screaming earache" as found in purulent otitis media. A young child may be irritable and pull at the ear. In milder cases, and as the ear recovers, gurgling and popping noises can be heard in the ear.

On examination one may see a yellow tympanic membrane and if a fluid level is present the diagnosis becomes easy. However, the eardrum may be dull gray, or slightly pink, or even perfectly normal. Pneumomassage using a Siegle otoscope or a closed-head electric otoscope must be done on both ears, otherwise the diagnosis will be frequently missed. Attempted movement of the drum with the pneumatic otoscope produces either a sluggish motion of the drum or no motion at all instead of the easily movable normal drum. The Rinne test is negative and there is a 15-20 decibel conductive hearing loss. The bone conduction may be better than normal and an air-bone gap may exist even with the air conduction within normal limits. Occasionally one finds a false nerve deafness on the audiogram when thick glue-like fluid causes immobility of both the oval and round window. Both conditions return to normal when the fluid is removed, but they make the interpretation of screening audiograms very difficult.

There is no single cause for serous otitis. One factor always present is blockage of the eustachian tube, but this alone is not enough to produce fluid. There must also be an inflammatory reaction. Blockage of the eustachian tube may be caused by many conditions. In children the most common cause is enlarged adenoids. In the summer the next most common cause is allergy. Upper respiratory infections or influenza are common causes in the winter. Nasal allergy, acute and chronic sinusitis, nasal septal deformity and cleft palate can all cause eustachian tube obstruction. Some children may have a congenitally small eustachian tube, but fortunately they usually "grow out of the problem."

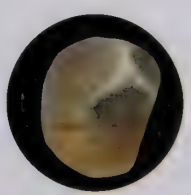
The first sign of a nasopharyngeal tumor is often a serous otitis. One must always rule this out in any adult who later in life develops repeated or persisting serous otitis. Causes sometimes overlooked are nasogastric tubes after surgery, simple obesity and cardiorenal disease, which may produce congestion in the mucosal lining of the eustachian tube. In recent years we have been seeing a new cause—acute otitis media, where the patient is adequately treated with antibiotics but where drainage has not been

established either through the eardrum or down the eustachian tube. A sterile exudate is left in the middle ear.

The inflammatory response may be caused by a marked negative pressure as in air otitis from flying, or it may be from a mild bacterial or viral infection in the middle ear. Serous fluid is a good culture medium and will frequently go on to purulent otitis media, especially if the original blockage was caused by an infectious process such as acute rhinitis or adenoiditis. When the infection heals there may be scarring in the middle ear mucosa. Mucous glands develop in this tissue and pour out a thick mucoid material. This ear usually looks normal until a pneumatic otoscope is used. The objectives in treating serous otitis are to remove the obstructing agent and to provide drainage from the middle ear. Often this can be accomplished by decongestants and nose drops. If large obstructing adenoids are present they should be removed. Sinusitis should be treated with oral decongestants or nose drops, plus antibiotics where indicated. Nasopharyngeal tumors should be treated. Allergies should be treated with antihistamines and, where indicated, by desensitization.

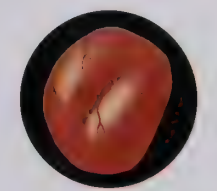
If the fluid does not clear with medical treatment within a week or two, a myringotomy should be done. If there is a question of active infection or if the fluid looks purulent, as is seen at the conclusion of acute otitis, cultures are taken. On adults this can be done in the office without anesthesia. It is no more painful than an intravenous needle for a blood test. A good safe topical anesthetic has a tremendous psychological value to the patient. Children under the age of 1 require no anesthesia. Between the ages of 1 and 3 anesthesia is not absolutely essential although a general anesthetic may be used to avoid the child's possible mistrust at follow-up examinations. I usually do the myringotomy at the same time as the adenoidectomy if the adenoids are enlarged. Once drainage has been established with decongestants or by myringotomy, positive pressure inflation of the middle ear is invaluable in forcing out the serous fluid and keeping it from reforming. The patient can do this himself by performing the Valsalva maneuver. This should be done several times a day, by taking a deep breath, holding the nose and blowing hard against the closed lips for a second or two.

In resistant cases where the fluid reforms as soon as the myringotomy heals, small polyethylene tubes are inserted through the myringotomy site. Insertion of the tubes, even in adults, usually requires an anesthetic. Good anesthesia can be obtained by infiltrating the canal wall with a local anesthetic, using a #27 needle. Once inserted the patient has no sensation of the tubes' presence. Be careful to caution the patient or parents not to allow any water to get into the ear canal while a myringotomy is open or a tube is in place. Water can be kept out by a pledget of lamb's wool in the ear canal or a cotton pledget thickly coated on the outside with petroleum jelly. I check these patients a week after a myringotomy to be sure it is healed and at two month intervals until the tubes have fallen out, usually within three to six months after insertion.

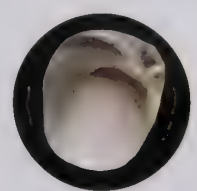


The mucoid type of fluid is so thick and tenacious that it is appropriately called a glue ear. It is aspirated only with difficulty through the eardrum, and occasionally must be removed through a tympanotomy. This thick, glue-like fluid is prone to recur, as the myringotomy usually heals long before the mucous membrane has returned to normal. Repeated myringotomies, as many as ten or twenty, were formerly required for this condition. Now polyethylene tubes are inserted initially when this thick, glue-like material is found. At times a subacute mastoiditis may accompany the serous otitis, which will necessitate a simple mastoidectomy before the condition can be eradicated. Usually the thin serous fluid readily responds to decongestants or to a myringotomy and removal of the eustachian tube obstruction. Occasionally, however, even serous fluid will repeatedly reform. For this, resection of the tympanic plexus of nerves which lies on the promontory of the middle ear has been carried out, as the tympanic branch of the glossopharyngeal nerve is the secretomotor nerve to the ear.

Failure to diagnose serous otitis is the most common cause of the recurrent, almost continuous otitis me-



Otoscopic Views



Normal

Acute Serous

Acute Purulent

Chronic Serous

dia seen in young children. In these cases a myringotomy will frequently provide a long-term cure without adenoidectomy or any other surgery. Failure to do this may allow the condition to go on to acute or subacute mastoiditis. Adhesive otitis media with scar tissue binding down the ossicles or tympanosclerosis may also result with permanent impairment of hearing. The prognosis for hearing with adhesive otitis or tympanosclerosis is usually poor. If the adhesions are removed, they reform, and the same is frequently true of tympanosclerosis even after a tympanoplasty. For many of these people a hearing aid is the only solution. The constant negative pressure in long standing serous otitis media may draw in either Schrapnell's membrane or the posterior superior portion of the eardrum forming a pocket to cause a chronic otitis media with cholesteatoma, which may not become apparent until twenty or thirty years later.

The non-medical complications of improper diagnosis or treatment may be even more serious. The irritable child, the frequent bouts of acute purulent otitis media with pain and fever, the expense of antibiotics and doctors, and the time lost from school or work affect the entire family.

In summary, serous otitis has many causes. There is a blocking of the eustachian tube and an inflammatory reaction in the middle ear mucosa, the latter usually caused by a mild infection. The treatment is to provide immediate drainage by decongestants and where necessary, by a myringotomy. The obstructing agent must be removed by surgery if it is adenoid or by oral decongestants, and antihistamines or nasal spray if it is an upper respiratory infection or allergy. Occasionally resistant cases require plastic tubes placed through the eardrum or other more radical surgery. Failure to treat properly leads to hearing loss which may be permanent, repeated acute otitis media or possibly even chronic otitis media with cholesteatoma.

Abstracts, Briefs and Commentaries

ULTRASONIC PULSE DETECTION

The simplest way of determining blood flow is palpation, but only very limited parts of the arterial system are palpable. Other methods can be used, such as arteriography, plethysmography, xenon-clearance and skin temperature measurement. A new method for evaluating the arterial blood supply in the extremities is described in detail, based on the use of reflected ultra sound, which has frequencies higher than the human ear can hear.

Reflected ultra sound has been used to register the movement of the anterior cusp of the mitral valve. Donald & Brown have mentioned its use for the diagnosis of aneurysms of the aorta, and Howry has employed it to demonstrate the large vessels of the extremities and neck. It has also been used to estimate the flow in blood vessels.

The principles of this new method are explained in considerable detail. There is no difficulty registering the pulse in a single artery along the extremity, but it is difficult to distinguish between branches of arteries that are close together. This new way of examining the arterial system is considered an improvement when the pulse is too weak to be palpated or when the vessel is too deep to palpate. The method is intended for the following purposes: diagnosis and localization of emboli, traumatic lesions of the arteries, evaluation of the pulsations in big arteries in chronic obliteration, continuous registration of the pulse distal in the extremity when operating on its arteries, and postoperative evaluation of the pulsation in the extremity after operation on its arteries.

THE DRUG PROBLEM AMONG YOUNG PEOPLE

"Turn on," "tune in," and "drop out." This statement has become the credo of a new generation of young people who have begun to solve their problems by the use of hallucinatory drugs. The taking of drugs is not a new

thing. For thousands of years various drugs have been used to alter human consciousness and distort reality. What is new, however, is the high incidence of participation among young people and the extent or encouragement of it by influential members of the literary and academic worlds.

Of all the hallucinogenic agents, LSD (lysergic acid diethylamide) and marijuana (cannabis) are most widely used. The chief objection to the use of LSD arises from a growing body of evidence that it produces irreversible changes in the life style and personality of those who use it. Physiological changes include impairment of the subject's ability to make realistic judgements and to retain rational beliefs. A person on LSD may feel he is omnipotent and hence impervious to certain laws of his environment. He may feel that he can jump out of a window without being hurt. There may be a preoccupation with isolated aspects of sensory experiences and with forms of thinking similar to psychosis. Most characteristic of all is the abandonment of long-term patterns of striving.

In the past, most drug users came from deprived socioeconomic backgrounds and preferred narcotics to other drugs. In general, the new users come from the middle class, have good educational background, and are often engaged in intellectual or creative pursuits. The physiologic effects of LSD have not been fully delineated, and the specter of genetic damage to this intellectual elite hovers over us.

The evidence of harmful effects of marijuana is less clear than for LSD. However, a study of individual case histories suggests that the use of marijuana does indeed entail risk. In most instances, marijuana does not cause the original psychologic conflicts; on the other hand, it contributes nothing to their solution, and in many instances may delay or prevent effective approaches to the solution of conflicts.

In one sense, it is misleading to talk about "the drug problem" as if it were an isolated phenomenon, for it is only one aspect of young people's position in contemporary society. If drug taking were not related to current social conditions and the individual's reactions to them, it would be much easier to deal with.

Among the young, experience with drugs has become a kind of social currency, a source of status and esteem. Within the drug movement, there is also an element of rebellion and protest against contemporary American society and its institutions. Young people are keenly aware of social injustice, the threat of nuclear war, and the ineffectiveness and downright hypocrisy of some persons in public authority. Some young people who take drugs reject all authority; on occasion their criticisms of society become so generalized that they reject most conventional values. Using drugs as a personal medium, they focus on their own subjective values and experience.

The methods by which alienated young people choose to show their disdain for conventional values make rational thinking about their behavior difficult for older people. Whereas the young usually put high priority on love, peace, idealism, and similar attributes, the appearance and behavior of some youth who take drugs often seem to be peculiarly designed to attract criticism. Long hair, outlandish fashions, lack of cleanliness, sexual laxity, disrespect for personal and public property, and a manner which appears arrogant and impulse-ridden frequently accompany experimentation with drugs.

We in the medical profession must find an effective way to deal with the drug problem, and it must involve respect for the individual taking drugs and

tolerance for their behavior. Drugs should be viewed as an incidental factor, considered in the same class as other forms of "acting-out" behavior and not as a central problem. We physicians are in a particularly good position to help educators in developing methods to cope with the problem. We must give the young people the facts in terms that can be clearly understood, without moralizing, and combine this approach with efficient enforcement of new legislation covering distribution of these drugs.

A STUDY OF 605 FATAL PULMONARY EMBOLISMS AND TWO SUCCESSFUL EMBOLECTOMIES

In this remarkable study from Heidelberg, Germany, all the fatal pulmonary emboli occurring at the University of Heidelberg Hospital from 1915 to 1960 (50 years) were reviewed. The incidence of pulmonary embolization clearly diminished following the two great wars. The authors feel this is due to a state of malnutrition in the general public. Body weight carried only scant prognostic significance. However, beyond the fourth decade of life, the incidence of embolism rose continually.

The time interval between the onset of acute, massive pulmonary embolism and death was less than 10 minutes in 76.2 percent. Only 17.2 percent survived more than 30 minutes. In 97 percent of the patients examined, the embolus originated from the lower half of the body. In only 11.4 percent was a small previous infarction noted. Two of six Trendelenburg operations for the extraction of pulmonary emboli were sucessful.

A SCAVENGER'S SCRAPS

Every now and then as I scavenge through recent medical journals, I run across scraps of imaginative prose that seem worth saving and showing to others. Because these pieces are well written, they need no abstracts or commentary; they speak for themselves.

Once there was a disease called lupus because it was like a wolf in eating the flesh. Then there was another disease called lupus erythematosus, because it was like lupus, though it is not lupus. Then there was another, called lupus erythematosus disseminatus, because it was like L.E., though it is not the same disease. And now there is a disease called lupoid hepatitis, because it is (remotely) like L.E.D., though it is not the same disease. A singular chain of resemblances. Should not the last member properly be called lupoidoidoidoid? It is time someone capped pseudo-pseudohyperparathyroidism.*

Angered by intrusions and displeased with libations of amniotic fluid, fibrinolysin, silicone, antihistamines and corticosteroids, the gods of the peritoneum in vengeance create intestinal adhesions.**

**Intestinal Adhesions. (editorial), New Engl J Med 277:657, 1967.

And the Great Sun shone and the land waxed warm and the Academies proliferated. And they suffered mutations so that some societies were no longer royal nor even academic, nor even learned, and they covered the land. And their Proceedings increased and multiplied and underwent mitosis and mutations. And some societies developed without publications and some publications developed without learned societies, and some publications and societies lost their learning, and a great cloud of societies and publications lay over the land.†

STUDIES IN CLINICAL SHOCK AND HYPOTENSION V. HEMODYNAMIC EFFECTS OF DEXTRAN

In this very significant study, 31 patients in shock, not due to blood loss, were treated with Dextran 75 or Dextran 40. Patients with elevated central venous pressure, indicating heart failure, were excluded from this series. After treatment, mean cardiac output increased, pulse decreased, blood pressure increased, urine output increased, and the patient's clinical picture improved. In 16 of the 31 patients, the hypotension was corrected by Dextran alone. The authors recommended consideration of Dextran for treatment of hypotension or shock, not due to blood loss.

Cohn, Jay N., Luria, Myron H., Daddario, Robert C., Tristani, Felix E.: Studies In Clinical Shock And Hypotension V. Hemodynamic Effects Of Dextran. Circulation 35:2:316, 1967.

The Essence of Tragedy

"I have of late—but wherefore I know not—lost all my mirth, forgone all custom of exercise; and indeed it goes so heavily with my disposition that this goodly frame, the earth, seems to me a sterile promontory."

So spoke Hamlet from his spiritual abyss after the perfidious murder of his father by his uncle; his mother's violation of decency by her hasty marriage to the murderer of her husband; and the solemn adjuration of his father's ghost that his son avenge his monstrous murder. How can we assess the shattering impact on any sensitive soul of this concatenation of events?

How could Hamlet remain devoted to his mother when she had dishonored her husband's memory? How could he show filial respect and political allegiance to his uncle who had usurped the throne? How could he avenge his father's murder except by compounding the sin of murder—from which his soul recoiled? Through the alembic of his emotional conflict the enormity of his moral dilemma became intolerable. Is it any wonder then that he cut himself off from his familiar world by closing his conduits. Not that he failed to speak! Rather he failed to communicate!

Had Hamlet been less introspective and more extroverted at this critical juncture he might have been galvanized into action that would have resolved his spiritual crisis instead of being paralyzed by indecision. Powerless to act, incapable of relating to his world on the warm, human terms that constitute living, he identified himself with nothing more than the earthy components of his physical body. Hence he wonders aloud: "And yet, to me, what is this quintessence of dust?"

Book Reviews

Opening a book is like opening a door, Turning a leaf's like a bend in the lane.
—Nancy Turner

BURNS, SHOCK, AND PLASMA VOLUME REGULATION—Carl A. Moyer, Harvey R. Butcher. Publication Date: Oct. 1967. Price: $18.50. C. V. Mosby.

This book is an excellent text expressing the views of the two well known authors on two subjects, shock and burns, that need to be mastered by each practicing physician. Unfortunately the average physician is so battered by the reams of reading material on these subjects in the journals that he does not have the time or the patience to 'sift the wheat from the chaff.'

As one first peruses this text he is apt to become disinterested because of what seems to be an overuse of tables, graphs, and figures to document the experimental work and the case histories. This should not deter one from obtaining the book, however, because it is a classic.

The use of large quantities of Ringers solution with lactate in the treatment of shock, and the silver nitrate treatment of burns are two contributions worth writing a book about. The section on burns is particularly well written. Certainly the therapy of burns will continue to change as the years go by, but for the present we must pay heed to the therapy recommended by the authors, for their results speak for themselves. The salvage of an occasional patient with a third degree burn over 50% of his body is noteworthy—to do it in the majority of cases treated is a medical milestone.

H. H. Farley, M.D.

PATIENTS, DOCTORS AND FAMILIES—Fay C. Lewis, M.D. Doubleday. Price: $4.95. Pages: 240.

From one University South Dakotan to another of the same vintage this reviewer extends his congratulations to the author who has expatiated on a large variety of human ills with a great deal of common ordinary horse sense.

Dr. Fay C. Lewis has called to our attention many functional ailments which every physician observes and understands, though he may be too impatient to deal with them properly. She has further revealed the numerous foibles and anxieties behind which some patients conceal their true illnesses.

This book should have its greatest value for "functional" patients suffering from psychosomatic disorders, and it should be recommended to them as profitable reading material by the physicians who must then rechannel their thinking.

If patients can be made to recognize and acknowledge these damaging processes Dr. Lewis will have more than adequately provided her bit for progress in the medical sciences.

Carl O. Rice, M.D.
Editor-in-Chief

SECOND DECENNIAL REVIEW CONFERENCE ON CELL TISSUE AND ORGAN CULTURE. National Cancer Institute Monograph 26. Pages: 229. Price $4.00. National Cancer Institute, Bethesda, Maryland, 1967.

The monograph is made up of papers presented before the Tissue Culture Association at Bedford, Pennsylvania, September 1966. Some of the topics were: Evidence for a "Governor" on protein synthesis in animal cells: Positive signals in serum, Genetic markers as tracers in cell culture, Histochemical approaches to cell characterization in vitro, Mechanisms of organogenetic tissue interaction, and "Spontaneous" neoplastic transformation of cells in vitro: Some facts and theories.

The paper on "Ultrastructural aspects of in-vitro development of monocytes into macrophages, epithelioid cells, and multinucleated giant cells" is provocative. The author describes the ultrastructure of the monocyte and its differentiation forms and illustrates them with 33 electron photomicrographs and five drawings. He concludes that the monocyte is the stem cell and one of its primary functions appears to be the augmentation of its cytoplasmic apparatus for synthesis and storage of lysosomal granules. The macrophage and the epithelioid cell are different forms of the same cell. This concept differs from that of many tissue culturists who contend that the mature lymphocyte can transform into a monocytoid cell, histiocyte and macrophage.

In summary, the theme of the conference was how cultured cells or tissues related to in-vivo progenitors, and how genetic systems may alter the activity of cells in vitro.

The monograph should be on the reference shelf of those working in the field of tissue culture.

E. M. Schleicher, Ph.D.
Minneapolis, Minnesota

"When you're finished with baby,
maybe you can tell me what I can do about my extra pounds."

Get them while they're easily reversible.

Obesity doesn't happen suddenly. This insidious process has its beginning—and the chances of reversing it are better—during the *first 10 to 15 pounds of weight gain.* When a new dietary pattern must be established, consider the adjunctive use of BAMADEX SEQUELS. Combining the proven *anorexigenic* action of d-amphetamine with the *tranquilizing* effect of meprobamate, BAMADEX SEQUELS controls appetite throughout the day, usually with a single capsule daily.

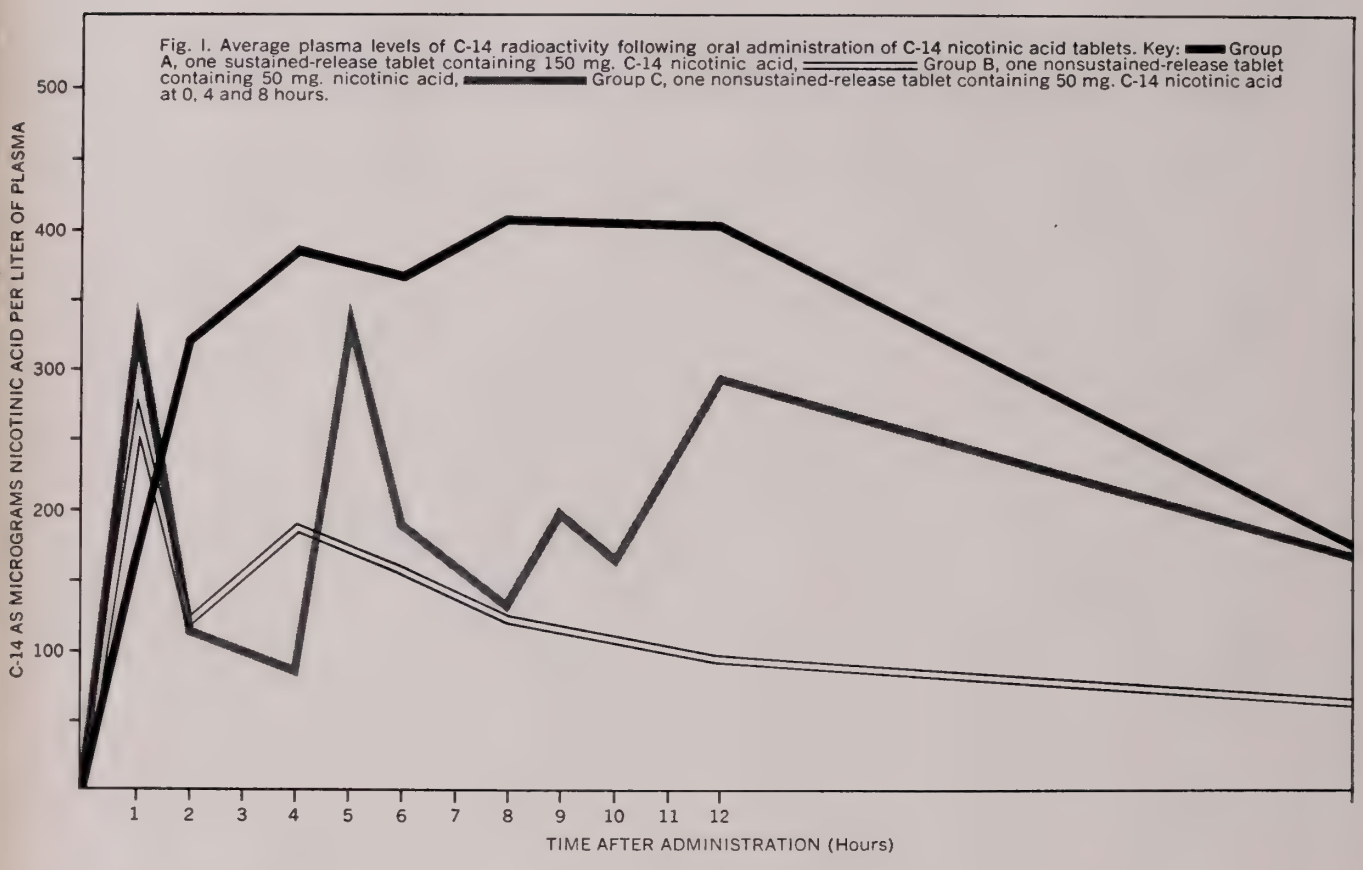
Contraindications: Dextro-amphetamine sulfate: In hyperexcitability and in agitated prepsychotic states. Previous allergic or idiosyncratic reactions to meprobamate.
Precautions: Use with caution in patients hypersensitive to sympathomimetic compounds, who have coronary or cardiovascular disease, or are severely hypertensive.

Dextro-amphetamine sulfate: Excessive use by unstable individuals may result in psychological dependence.

Meprobamate: Careful supervision of dose and amounts prescribed is advised, especially for patients with known propensity for taking excessive quantities of drugs. Excessive and prolonged use in susceptible persons, e.g. alcoholics, former addicts, and other severe psychoneurotics, has been reported to result in dependence on the drug. Where excessive dosage has continued for weeks or months, reduce dosage gradually. Sudden withdrawal may precipitate recurrence of preexisting symptoms such as anxiety, anorexia, or insomnia; or withdrawal reactions such as vomiting, ataxia, tremors, muscle twitching and, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, reduce dosage and avoid operation of motor vehicles, machinery or other activity requiring alertness. Effects of excessive alcohol consumption may be increased by meprobamate. Appropriate caution is recommended with patients prone to excessive drinking. In patients prone to both petit and grand mal epilepsy meprobamate may precipitate grand mal attacks. Prescribe cautiously and in small quantities to patients with suicidal tendencies.
Side Effects: Overstimulation of the central nervous system, jitteriness and insomnia or drowsiness. Dextro-amphetamine sulfate: Insomnia, excitability, and increased motor activity are common and ordinarily mild side effects. Confusion, anxiety, aggressiveness, increased libido, and hallucinations have also been observed, especially in mentally ill patients. Rebound fatigue and depression may follow central stimulation. Other effects may include dry mouth, anorexia, nausea, vomiting, diarrhea, and increased cardiovascular reactivity.

Meprobamate: Drowsiness may occur and can be associated with ataxia; the symptom can usually be controlled by decreasing the dose, or by concomitant administration of central stimulants. Allergic or idiosyncratic reactions: maculopapular rash, acute nonthrombocytopenic purpura with petechiae, ecchymoses, peripheral edema and fever, transient leukopenia. A case of fatal bullous dermatitis, following administration of meprobamate and prednisolone, has been reported. Hypersensitivity has produced fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, stomatitis, proctitis (1 case), anaphylaxis, agranulocytosis and thrombocytopenic purpura, and a fatal instance of aplastic anemia, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation. Massive overdosage may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Bamadex® Sequels®



Dextro-Amphetamine Sulfate (15 mg.) with Meprobamate (300 mg.) Sustained Release Capsules

Lederle

LEDERLE LABORATORIES

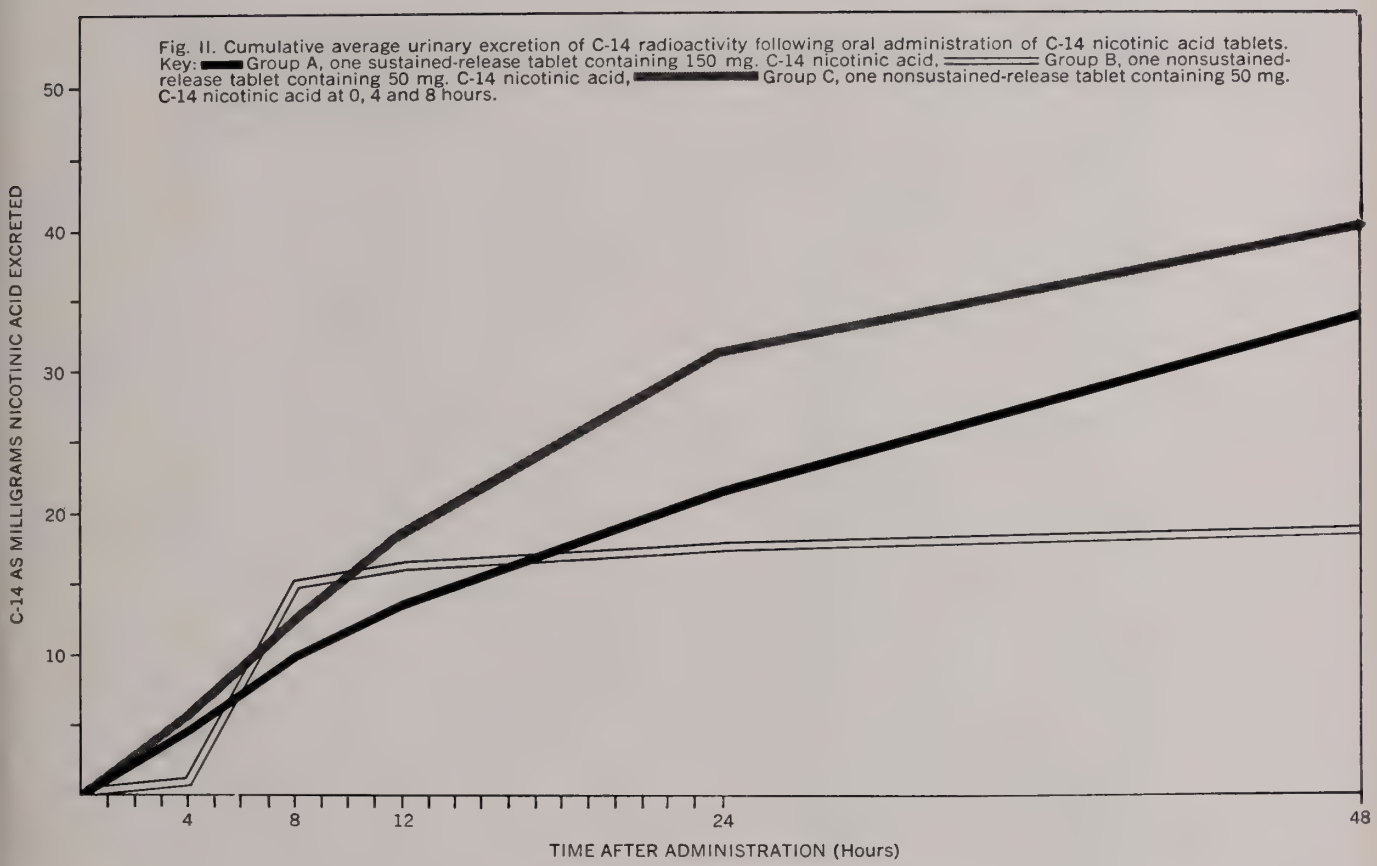
Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by absent-minded patients)



Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylenetetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

ıged and debilitated

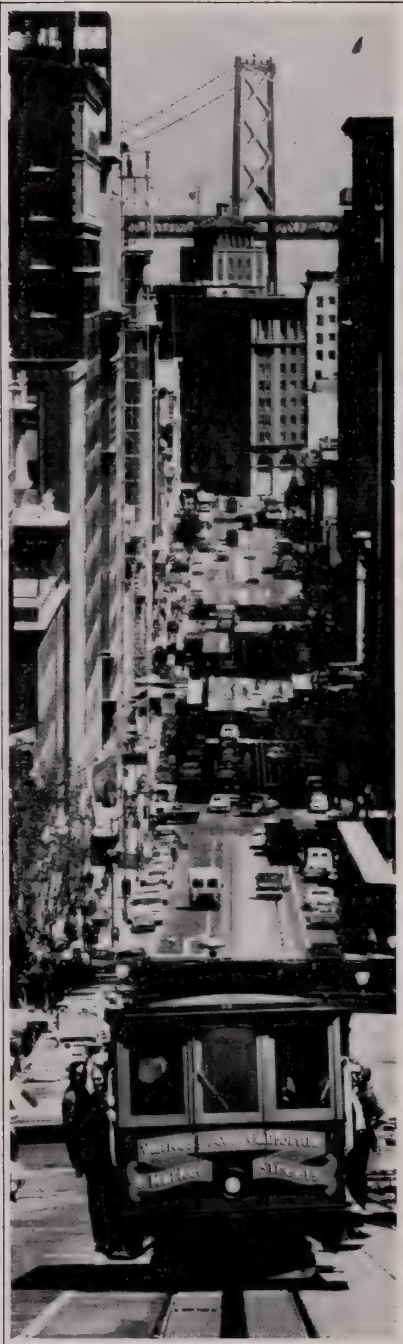
less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.



Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

SAN FRAN CISCO AMA '68

The excitement of San Francisco's famous sites is waiting for you. Chinatown, the Golden Gate Bridge, Fisherman's Wharf, Telegraph Hill, will add to five memorable and stimulating convention days. Plan to attend now and look forward to an excellent convention in a city of unlimited charm.

Continue your postgraduate education with a varied program of • four General Scientific Meetings on Auto Accidents, Health Care Planning, Infectious Diseases, Treatment of Advanced Malignant Disease • 23 Section Programs • Color Television • Medical Motion Pictures • and over 600 scientific and industrial exhibits. All are designed to bring you up-to-date on what is making medical news today. You will attend lectures by the nation's outstanding medical authorities and discuss with them the significant advances in medicine.

In addition the AMA TV network will present more than 40 hours of convention news.

Reserve now for the Scientific Awards Dinner in honor of the Scientific Award Winners—Wednesday, June 19, 1968. Since space is limited, we suggest you make your reservations before June 3, 1968. Tickets are $10.00 each, payable in advance.

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, May 6, 1968.

The Minnesota Thoracic Society and the Minnesota Respiratory Health Association announce a second award contest for medical students, interns and resident physicians in Minnesota.

(A) An award of $200.00 is offered for the best paper submitted by a senior medical student or intern on some aspect of respiratory disease, preferably based upon laboratory or clinical investigation.

(B) An award of $300.00 is offered for the best paper submitted by a resident physician based upon clinical or laboratory investigation in the area of respiratory disease.

Further information may be obtained from the Secretary. Entries should be submitted by September 1, 1968 to: David E. Dines, M.D., Secretary, Minnesota Thoracic Society, Mayo Clinic, Rochester, Minnesota.

Guest Speaker—Dr. Denton Cooley

Annual meeting of the Minnesota Chapter of the American College of Chest Physicians, May 14, 1968 in Plummer Hall, Mayo Clinic, Rochester. Dinner will precede the meeting which will start at 8:00 p.m. Guest speaker for the evening will be Dr. Denton Cooley. His talk will be "Surgical Treatment of Thoracic Aneurysms, Indications, Special Problems and Results." Everyone is invited. Contact: Dr. Drew Miller of the Mayo Clinic.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Suicide*

The Nondiminishing Rate

RONALD MARIS**
Hanover, New Hampshire

WE ARE NOT preventing suicide in the United States. In 1960 the suicide rate in the U. S. was about 11 per 100,000 population, almost exactly the same as in 1900. During those 60 years life expectancy has increased from about 35 to 70 years. Death from scarlet fever, typhoid fever, measles, diphtheria, and whooping cough has been virtually eliminated; death from tuberculosis and pneumonia are less than one-fifth as frequent as they were in 1900. Death by nephritis has been halved. Generally, the crude death rate has decreased from 17.2 per 1,000 population to 9.6 from 1900 to 1960.

All this means that suicide is becoming an increasingly important factor in the death rate. In fact, if future generations want to lower the death rate they are well-advised to focus on the prevention of suicide and accidents, not on so-called natural deaths. Most of us do not want to live much beyond 70 years, but we are concerned about unnecessary, premature death. There is considerable evidence to suggest that accidents and suicide have much in common: that they spring from common causes. Indeed, many accidents are probably disguised suicides. There is evidence that not only has suicide failed to decrease over the years but that, especially in some groups, it has actually increased. The Metropolitan Life Insurance Company discloses that in the last 10 years the suicide rate has increased 10 percent among white males in the U. S., but 33 percent among non-white males. The corresponding figures for females are 49 and 80 percent. These changes are primarily the result of higher suicide rates among younger persons, ages 15-24.

The Ambivalence of a Suicide

Suicides are notoriously ambivalent about dying, which raises the interesting possibility of our *right* to simply respond to the life-affirming side of their motivation, rather than the life-denying side.

A few years ago a member of my doctoral examination committee asked me in all seriousness if I really thought that suicide was a social problem. "After all," he said, "It's still true that the typical suicide is an old, white male, who is single and usually in poor health, often alcoholic. Given the present population explosion would not the world be better off without these people?" I suspect that many of us feel the same way. Certainly in your work as physicians you must ask yourselves periodically, whether some people should not be allowed to die, especially in the case of clearly terminal illnesses which are painful and expensive.

The Right to Die

There is the further question whether or not people have the right to terminate their life, since it is their life. Philosophers David Hume and Bertrand Russell have both defended this right. In fact, one way of transcending death is to elect it, rather than let it eat away at you. Surrender can be victory! Life alone is not our goal, but life with purpose and quality. Nobel prize-winning physicist, Percy Bridgman, killed himself and left this note: "My work is over, why wait?" Since the suicide rate for men is highest at retirement age, I suspect that many of us can

---

*Presented to the staff of the Fairview Hospital, Minneapolis, Minnesota, in December of 1967. Readers who wish references and tables are encouraged to write the author for another manuscript in which the problem of preventing suicide is given a more scholarly treatment.

**Assistant Professor, Dartmouth College, Hanover.

sympathize with Bridgman's logic.

The Right to Reconsider

Suicide prevention centers are possible because we believe that potential suicides have the right, indeed the obligation, to reconsider suicide under less agitated and confused circumstances. The rights of the relatives and associates of the suicide have to be weighed; for example, does not his wife have the right to his support and companionship? Don't his children have the right to escape the social stigma of being labeled by their schoolmates as children of a suicide?

Suicide vs. Homicide

Let me suggest that we should be ambivalent about suicide because the suicide rate and the homicide rate often are inversely related. I know of few populations in which it has been possible to reduce both rates simultaneously. This suggests that to prevent suicide is to cause homicide and lesser acts of aggression. (In fact Menninger called suicide "Murder-in-the-hundred-and-eightieth-degree.") Is not suicide to be preferred to homicide? I sometimes justify my killing deer on the grounds that it keeps me from killing myself. This reasoning is not as far-fetched as it may seem. It is a fact that a nation's suicide rate always drops sharply during engagement in an international war. We also know that Negroes have very low suicide rates, but that their homicide and assault rates are very high. All of which makes me wonder if suicide rates have remained high in part because we want them to.

Suicidal Warnings

Seventy-five percent of all suicides have seen a physician within four months prior to their death. Thus, if doctors were sensitized to suicidal warnings and made referrals to the psychiatric unit or local prevention centers, the suicide rate could probably be lowered significantly.

Alcoholic or Depressed

A study in St. Louis showed that 75 percent of all suicides were either depressed or alcoholic or both (Menninger felt that alcoholism was a suicidal equivalent). Further, potential suicides do communicate their intention to kill themselves; in fact, 80 percent of all suicides have made a previous unsuccessful attempt. This means that four out of five gave dramatic warning of their intent to kill themselves. Usually, when the probability of suicide is high, the person will have a definite plan of action (the more specific the plan, the higher the lethality). Often, just before the act, appetite falls off, sexual activity diminishes, insomnia is present, a will may be drawn up, and previously valued possessions may be given away.

Social Factors

Certain types of people are more prone to suicide than others. The most common suicide is 50 to 70 years old, white, male, unmarried, and of a lower social class.

Personality Types

The French sociologist, Emile Durkheim, has argued that socially suicides are disproportionately isolated ("egoistic") and unregulated ("anomic"): living in a social environment of relative normlessness: without external restraint. In my Chicago research, I found a high negative correlation between the suicide rate and population per household, controlling for other relevant variables.

Studies of case histories reveal that, as children, suicides were often subjected to high parental severity while they were dependent upon others and dared not agress against them. They also tended to be normative virtuosos, unable to deviate from internalized role expectations; this inflexibility led to an inability to deal adequately with failure; to justify their actual performances; to shift their goals. They were easily shamed and showed high levels of guilt and hopelessness.

Preventive Programs

Not only has there been too little response to the cry for help, but much of the action undertaken has been misguided and premature: misguided in the sense that the programs were clearly not directed towards those with a high probability of suicide, but rather toward relatively minor, non-suicidal crisis situations. Premature in the sense that huge sums of federal money have been poured into unrewarding pro-

grams initiated without the guidance of solid, basic research.

The Prevention Center vs. The Morgue

The suicide prevention center in Chicago tended to see manic, young, married females (i.e., low lethality cases), while the coroner saw depressed, old, unmarried males. Clearly, the persons elevating the suicide rate are not contacting the suicide prevention center. Something is fundamentally wrong with the suicide prevention program. For example, why use a telephone as the major instrument of contact? Does it make any sense to expect a 65-year-old male who is depressed and hopeless (i.e., who wants to die) to pick up the telephone and pour out his soul to some young, female volunteer? Emphatically not.

Basic Research

If we are ever going to prevent suicide, basic research is the only answer. First, we must be clear on the nature and types of suicide. Grasp of the principles of completed suicides must precede design of prevention programs. Also, experiments must be conducted with control groups! Although it is always a moral problem to design an experiment which exempts some human beings from treatment while treating others, we have little to lose, since present programs have largely been failures anyway. Once successful intervention programs have been devised, the scope of treatment can be generalized.

Nonprofessional Management

Another reason for prior failure is that nonprofessional religious groups have initiated much of the suicide prevention movement (e.g., The Samaritans in London and Rescue Incorporated in Boston). In spite of their good intentions, ministers are not qualified to manage suicide prevention centers alone. Psychologists, psychiatrists, M.D.'s, and sociologists are needed.

Warning Signs

Acute and Chronic Suicides

There are different types of suicide; some are easier to prevent than others.

An acute situation might exist for a 29-year-old woman whose grandmother and mother both suicided on their 30th birthdays. Chances are good that the young woman will be all right, if you can get her past her 30th birthday. Other persons may have a style of life, physical or psychological attributes, that continually goad them to try suicide until they finally succeed. Marital problems, physical deformities, mental illness can all lead to chronic attempts. Remember that 80 percent of all suicides have tried suicide at least once before, and they often succeed just when they seem to be improving: when they regain the energy needed to kill themselves. One of the most dangerous times is the three-month period immediately following the beginning of improvement after a depression.

Appeal vs. Ordeal Suicides

We can also distinguish between "appeal" suicides and "ordeal" suicides. Many women attempt suicide as an ultimate appeal to their husbands to improve an unhappy marital relationship. If the appeal is successful, the possibility of future suicide is lessened considerably. On the other hand, the prognosis is not good for a man who is undergoing the ordeal of growing old, living alone, feeling ill more often than well, being unable to work, etc.

Ecological Groups

Once the profile of high-risk groups has been drawn, it is reasonable to assume that mass intervention programs might be aimed at certain ecological groups. For example, the areas with the highest suicide rates in Chicago are in skid-row areas (Madison & Halsted area) and on North Michigan Avenue. Perhaps social workers could invade these areas and institute measures aimed at minimizing social isolation and anomy.* The basic change from present suicide prevention center programs would be the decentralization and invasion of services. Communities with low suicide rates are usually populated by religious fundamentalists, have highly legalistic and authoritarian government, are extremely poor and uneducated (says Durkheim), and have high rates of assault and homicide. On the other hand, communities with high suicide rates include many of the nation's outstanding cities: viz., Berkeley, San Francisco, Los Angeles, Miami, Denver, Seattle, and St. Louis (Minneapolis is 13.5/100,000; just

*See Test Your Word Score Page 649.

above the mean). Maybe we simply cannot have our cake and eat it too.

Communication Channels

Another key question would be what communication channels might be open to the high-risk group, besides the telephone. Perhaps television, bars, and liquor stores, could be utilized.

Comments

We should consider a control dilemma of major proportions. I am not sure that most of us would want to live in the kind of community which would minimize suicide. Perhaps a high suicide rate is one of the necessary costs of a certain style of life, of a certain level of civilization.

In Aldous Huxley's classic work, *Brave New World*, a world very much like what ours is becoming, suicide was unheard of, even inconceivable. In the closing pages of the book the savage, an Indian brought into the Brave New World, wonders if happiness is the end of life; if the completely comfortable life is worth living:

"What you need," the savage went on, "is something with tears for a change. Nothing costs enough here . . . exposing what is mortal and unsure to all that fortune and death dare, even for an eggshell. Isn't there something in that?" he asked, looking up at Mustapha Mond (a world controller). "Quite apart from God—though of course God would be a reason for it. Isn't there something in living dangerously?"

"There's a great deal in it," the controller replied. "Men and women must have their adrenals stimulated from time to time."

"What?" questioned the savage, uncomprehending.

"It's one of the conditions of perfect health. That's why we have made the V.P.S. treatments compulsory."

"V.P.S.?"

"Violent passion surrogate. Regularly once a month. We flood the whole system with adrenin. It's the complete physiological equivalent of fear and rage. All the tonic effects of murdering Desdemona and being murdered by Othello, without any of the inconveniences."

"But I like the inconveniences."

"We don't," said the controller. "We prefer to do things comfortably."

"But I don't want comfort. I want God, I want poetry, I want real danger, I want freedom, I want goodness, I want sin."

"In fact," said Mustapha Mond, "you're claiming the right to be unhappy."

"Not to mention the right to grow old and ugly and impotent; the right to have syphilis and cancer; the right to have too little to eat; the right to be lousy; the right to live in constant apprehension of what may happen tomorrow; the right to catch typhoid; the right to be tortured by unspeakable pains of every kind."

There was a long silence.

"I claim them all," said the savage at last.

So this is where we stand. We are not preventing suicide, because we are ambivalent about its worth, insensitive to its symptoms, too ready to act on an incomplete understanding of it, and thus unable to control it. I close by asking you: Is this a sorry state of affairs or not? Should suicide be prevented and how? Or should men have the right to be unhappy and to end their own lives? And perhaps most importantly, can we preserve the right to be unhappy and at the same time prevent suicide?

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

b.i.d.

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, consider DECLOMYCIN 300 mg b.i.d.

The maintenance dosage of DECLOMYCIN 300 mg can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective, because of high serum binding and slow renal clearance.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE
Lederle

Prescribing information on next page.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE
b.i.d.

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.

Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg every 6 hours for a minimum of 4 doses or 300 mg every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg every 6 hours or 300 mg every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg in 3 divided doses for six days.

Law and Medicine

Today's Top Malpractice Risks*

(1) The author reviewed 1000 Malpractice Claims. Many doctors are not aware of the recent trends that have made certain risks today's top malpractice threats.

Three specific faults present the greatest malpractice dangers: (1) inadequate medical records; (2) colleagues' and assistants' mistakes; (3) errors in diagnostic tests. Court awards are rising steeply, especially for deaths of children and housewives. Malpractice experts with whom the author conferred agreed that if all private practitioners would take steps to minimize these three risks, the current incidence of malpractice claims would drop shortly. Four types of faulty record-keeping are recorded. (1) Surgeons invite trouble when they fail to keep adequate records of surgical operations in detail, fail to record complications and bad results, or fail to record the condition of the patient before, during, and after surgery. The Alaska Supreme Court stressed the importance of precise records; when lacking, surgeons face the jury with res ipsa loquitur (the thing speaks for itself). The case in point was a patient who suffered a division of a recurrent laryngeal nerve during a routine subtotal thyroidectomy. The operative report was so sketchy that an expert medical witness could not give an exact opinion on negligence. The Supreme Court ruled that the patient did not need any more proof of negligence.

The effect of the Alaska Supreme Court ruling has been felt in other jurisdictions. It led to a recent $48,500 settlement, paid to a man who lost his right kidney because of a surgical mishap. In separating multiple adhesions, the right ureter was divided. Defense experts agreed that the operative slip alone did not constitute malpractice. The operative report was not dictated until three weeks after surgery and did not mention either the adhesions or their location. The judge stated he was sending the $150,000 claim to the jury; but it was promptly settled out of court.

Astute trial lawyers make it a point to compare the date of surgery with the date of the dictation of the report.

(2) Failure to make a record of allergy. A four-man medical group paid $116,000 settlement for a death because one of its members was guilty of a fatal omission. A nurse, in the doctor's presence, gave an injection of penicillin. The patient had a reaction but was able to leave the office. The doctor was urgently called away and forgot to record the reaction. Months later the same patient came to the same office with a sore throat. Another doctor of the group checked the record and ordered penicillin. The patient died within an hour of the injection. A New York malpractice attorney states that anyone who does not record allergic reactions is exposing himself to a lawsuit, as no doctor can remember the peculiarities of all his patients. Records are even more necessary when treatment is given by a partner, a colleague or a hospital physician who may be ignorant of a known reaction.

An instructor was away lecturing to his class on allergy. A patient who he knew was sensitive to aspirin was waiting to see him at his office. A nurse gave the patient a small dose of aspirin. The treatment proved fatal.

*John H. Tovey, J. D. Medical Economics—July 10, 1967. In 4 parts.

Fortunately the family did not sue.

(3) Failure to report negative findings. A judge advised a doctor to settle a claim for $4,000. An expert witness had stated that a stillborn child should have been delivered by cesarean section. The doctor insisted that he thought the patient could deliver the child normally despite a small pelvis. The plaintiff's lawyer asked the $64 question: "Look at your records and tell me how small the pelvis is." The doctor couldn't because he had no record of any measurements. As advised by the judge, a settlement was negotiated.

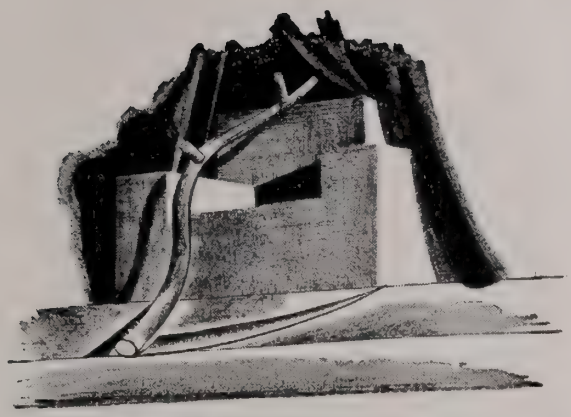
Melvin Belli, the California trial expert, states: "If a doctor fails to record negative findings he'll be hard pressed to prove to a jury that he did the examination, or ordered the test in question." Belli's words are given substance by a settlement for $25,000 of a case against an internist which took every penny he had. There were no records of allergy or other tests. The doctor said the tests were negative, why write them down and waste ink.

(4) Failure to record significant phone conversations. Malpractice lawyers have for years warned against giving phone consultations. If a doctor does give one, he should make detailed notes of treatment and medications prescribed. A doctor had a lawsuit brought against him because of a brain-damaged infant. The fatality was the result of an over-dose of medicine, the result of a mistaken phone order. The pharmacist swore he typed the label calling for an adult dose as the doctor instructed. The doctor swore he did not so order. Since the physician had no record of the conversation, his insurance carrier decided to settle.

An internist, on the phone, advised on the care of a 16-year-old boy with abdominal pain, without suggesting a personal visit or hospitalization. The boy died of a ruptured appendix and peritonitis. The mother sued for $100,000. She swore that she told the doctor her son had abdominal pain, elevated temperature and abdominal tenderness The doctor remembered none of this and had no record. He stated that if symptoms had indicated an emergency, he would have responded. A settlement was made for $18,000.

Note: During the years the science of medicine has advanced and so has the practice of law.

I can recall when malpractice insurance for $5,000 to $25,000 was considered adequate. The annual premium was about $25.00. At present those amounts of insurance are no longer adequate in view of the growing generosity of the courts.



Stanley R. Maxeiner, Sr., M.D.
Minneapolis, Minnesota

The Question

At some time in life every man has what is commonly called "a chance." The question is *not,* what *is* that chance, but *what will he do with it?* There are few questions in this life to which the solution is more important to each puzzled mortal than that which applies to *man's life,* from its first sleep in the cradle, *what will he do with it?*—E. Bulwer Lytton

I prefer the wicked rather than the foolish; the wicked sometimes rest.—Alexandre Dumas (pere)

In Memoriam

Our life contains a thousand springs,
And dies if one be gone;
Strange that a harp of thousand strings
Should keep in tune so long.—Watts

JOHN K. GROTTING, M.D.

Dr. John Grotting, 52, widely-known Minneapolis plastic surgeon, died February 8. A native of Minneapolis, he received his medical degree from the University of Minnesota and after interning a year in Receiving Hospital at Detroit, Michigan, he became a fellow at the Mayo Clinic in Rochester.

He was a member of the American Society of Plastic Surgeons, American Medical Association, Hennepin County Medical Society, Minnesota State Medical Association, Minnesota Surgical Society and the Mayo Alumni Association. He also was a fellow of the American College of Surgeons and a diplomate of the American Board of Plastic Surgeons.

He is survived by his wife, four sons and a daughter.

WILLIAM D. BROWN, SR., M.D.

Dr William D. Brown, Sr., 65, Minneapolis physician for forty years, died March 19. He graduated from Central High School and attended the University of Minnesota where he received his medical degree in 1925.

Dr. Brown was an active member of the National Association for the Advancement of Colored People and also a member of the American Medical Association, Hennepin County Medical Society and the Minnesota State Medical Association.

He is survived by his wife and a son, Dr. William Brown, Jr. of Minneapolis.

JOSEPH D. WALLER, M.D.

Dr. Joseph D. Waller, 86, Pine City ophthalmologist, died January 6. He was born in Litchfield and attended the University of Minnesota where he obtained his medical degree in 1905.

He was a member of the East Central Medical Society, the American Medical Association and was a 50 Club and Associate Member of the Minnesota State Medical Association.

He is survived by his wife.

MARTIN NORDLAND, M.D.

Dr. Martin Nordland, 79, Minneapolis surgeon, died March 23. He specialized in thyroid surgery and was listed in "Who's Who in America."

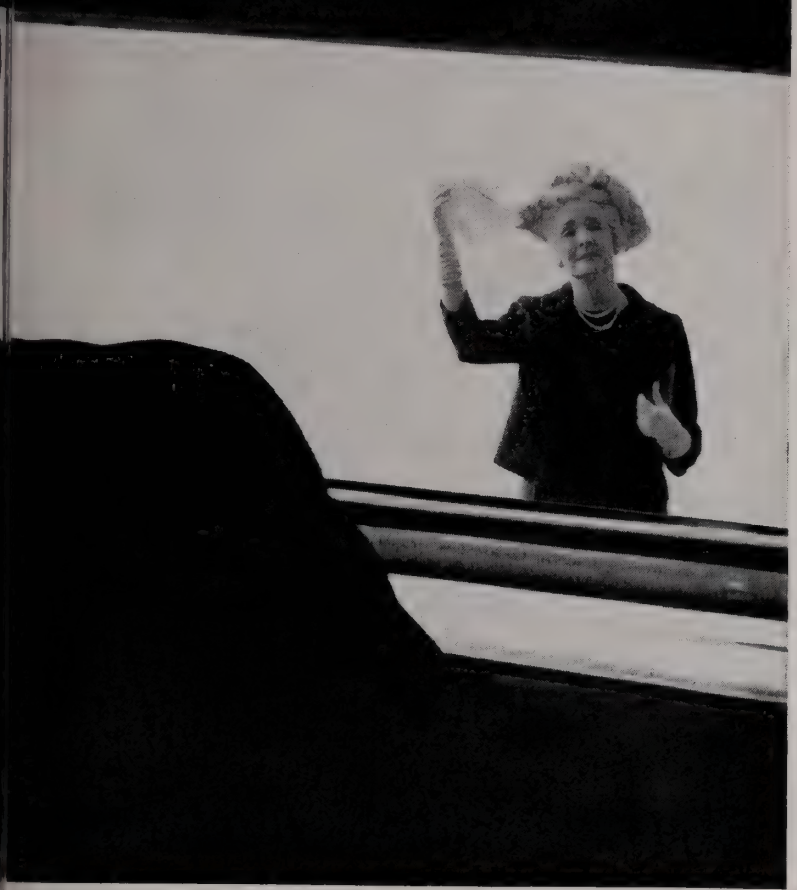
A native of Austin, Minnesota, he received his medical degree from the University of Minnesota in 1911 and was a member of the faculty in the Department of Surgery at the University of Minnesota. Dr. Nordland was chief of staff at Northwestern Hospital in 1931 and 1932, a member of the founders' group of the American Board of Surgery and in 1934 and 1935 was president of the Minneapolis Surgical Society.

He was a former associate editor of LANCET, a former vice-president of the Hennepin County Medical Society, a member of the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife and a daughter.

ROBERT SCHWYZER, M.D.

Dr. Robert Schwyzer, 77, former chief surgeon of the Kreisspital, Bulach, Switzerland, died following a prolonged illness October 28, 1967.



Dr. Robert Schwyzer, a relative of the late Dr. Arnold Schwyzer of St. Paul and Dr. Gustav Schwyzer of Minneapolis, received his training at the University of Zurich, Switzerland. He came to Minnesota and practiced medicine at Blackduck for two years transferring to Minneapolis in 1927 to become associated with Dr. Gustav Schwyzer and a member of the Hennepin County Medical Society. In 1932, he returned to Switzerland.

He is survived by his wife, a son and a daughter.

Indications: Tofrānil is recommended for the treatment of depressive states of diverse psychopathology.
Contraindications: The concomitant use of Tofrānil and monoamine oxidase inhibiting (M.A.O.I.) compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur. Potentiation of adverse effects can be serious or even fatal. An interval of at least 7 days after M.A.O.I. therapy has been discontinued should be allowed before Tofrānil may be substituted. Initial Tofrānil dosage should be low, increases should be gradual, and the patient's progress should be carefully observed.
Warning: Clinical reports have suggested that there may be a risk of teratogenesis associated with the use of this compound during the first trimester of pregnancy. Unless, in the opinion of the prescribing physician, the potential benefits outweigh the possible risks, Tofrānil should not be used during the first trimester of pregnancy.
Cardiovascular complications, including myocardial infarction and arrhythmias, have occasionally occurred in susceptible individuals. Patients with cardiovascular disease should be given the drug only under careful observation and in low dosage.
Precautions: Since suicide is always a possibility in severely depressed patients and one which may persist until significant remission occurs, such patients should be carefully supervised during early treatment with Tofrānil. Some severely depressed patients may also require hospitalization and/or concomitant electroconvulsive therapy.
Because of its anticholinergic effect, caution should be observed in prescribing Tofrānil for patients with increased intraocular pressure.
In rare instances, transient cardiac arrhythmias have occurred in hyperthyroid patients and in patients receiving thyroid medication when Tofrānil was added to the regimen.
Imipramine may block the pharmacologic activity of guanethidine and other related adrenergic neuron-blocking agents.
The drug is not recommended at the present time in patients under 12 years of age.
Adverse Reactions: Dryness of the mouth, tachycardia, constipation, disturbances of accommodation, sweating, dizziness, weight gain, urinary frequency or retention, nausea and vomiting, peripheral neuritis, mild parkinson-like syndrome, tremors, rare cases of falling in elderly patients, confusional states (with such symptoms as hallucinations and disorientation), activation of psychosis in schizophrenics and agitation (includ-

When a milestone in life is marred by depression...

Often in the mind of the lonely, widowed, depression-prone individual, she's not gaining a daughter...she's losing a son. The occasion may be marred by depression with such symptoms as feelings of sadness, incapacity, helplessness and hopelessness.

Tofrānil often relieves symptoms of depression.

As maintenance therapy during the active phase of depression, it may help prevent relapse.

The use of Tofrānil in patients receiving M.A.O.I.'s is contraindicated.

In patients with cardiovascular disease, hyperthyroidism or increased intraocular pressure; or in those receiving anticholinergics (including antiparkinsonism agents), thyroid medication, or antihypertensive adrenergic neuron-blocking agents; and in those in their first trimester of pregnancy, the special precautions listed in the prescribing information should be carefully observed.

Toxic reactions severe enough to require discontinuation of Tofrānil are uncommon. However, for complete details, please refer to the full prescribing information.

Tofrānil® imipramine hydrochloride Geigy

ing hypomanic and manic episodes) which may require dosage reduction and/or addition of a tranquilizer or temporary discontinuation of the drug, epileptiform seizures, orthostatic hypotension and substantial blood pressure fall in hypertensive patients, purpura, transient jaundice, bone marrow depression including agranulocytosis, sensitization and skin rash including photosensitization, eosinophilia, and mild withdrawal symptoms on sudden discontinuation after prolonged treatment with high doses. Occasional hormonal effects (impotence, decreased libido, and estrogenic effects) may be observed. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those using anticholinergic agents (including antiparkinsonism drugs).
Outpatient Adult Dosage: Initially, 75 mg. daily, increased, if necessary, to 150 or 200 mg. Maintenance dosage may be lower, 50 to 150 mg. daily, if possible.
Geriatric and Adolescent Dosage: Initially, 30 or 40 mg. daily, which may be increased according to response and tolerance. It is usually unnecessary to exceed 100 mg. daily.
A lag in therapeutic response, lasting from a few days to a few weeks, should be expected. When dosage recommendations are already being followed, increasing the dosage does not normally shorten this latency period and may increase the incidence of adverse reactions.
Availability: Tofrānil: Round tablets of 25 and 50 mg.; triangular tablets of 10 mg. for geriatric and adolescent use; and ampuls, each containing 25 mg. in 2 cc. for I.M. administration.

Annual Meeting

Rochester Will Host Our Annual Meeting

IT'S ANNUAL MEETING time in Rochester. In a setting of everything medical, the Minnesota State Medical Association will meet May 13, 14 and 15 for its 115th Annual Meeting. Members of the Zumbro Valley Medical Society will be the hosts for the 1968 event. Members of the Woman's Auxiliary will hold their 46th Annual Meeting in conjunction with the business and scientific sessions of the Association.

Business Sessions

The House of Delegates will meet for its opening session Sunday, May 12, at 2:00 P.M. in the Kahler Hotel. Delegates and interested physicians are advised to note the change in time for the second session of the House, which has been scheduled to convene Monday evening, May 15, at 7:30 P.M., a departure from its traditional Tuesday morning second session. Reference committees will meet at 8:00 P.M. Sunday to consider committee reports and resolutions. A second session of reference committee meetings will be scheduled, if needed, Monday morning at 9:30 A.M.

Because of the important role which the Reference Committee hearings and House of Delegates meetings play in determining future policy of the Association, the Council urges all members to attend these sessions and especially, the reference committee meetings where opinions of members will be welcomed.

Many of the nearly fifty scientific and nonscientific committees of the Association have scheduled 7:30 A.M. breakfast meetings Monday, Tuesday or Wednesday. Members of the committees are urged to attend their meetings and actively participate in matters scheduled for discussion and action.

Scientific and Technical Exhibits

The Committee on Scientific Assembly has

115th Annual Meeting

Program Timetable

Sunday, May 12

2:00 P.M.	House of Delegates—Kahler Hotel
6:00 P.M.	New Members, County Officers and Delegates Dinner—Kahler Hotel
8:00 P.M.	Reference Committees of the House of Delegates—Kahler Hotel

Monday, May 13

7:30 A.M.	Committee Breakfasts—Kahler Hotel
8:45 A.M.	Registration at Mayo Civic Auditorium— Exhibits open 8:45 a.m. to 5:00 p.m.
9:00 A.M.	Morning scientific session begins—Mayo Civic Auditorium
9:30 A.M.	Reference Committee Meetings—(If needed)—Kahler Hotel
12:15 P.M.	Round Table Luncheons—Kahler Hotel
2:00 P.M.	Afternoon scientific session begins—Mayo Civic Auditorium
7:30 P.M.	House of Delegates—Kahler Hotel
7:30 P.M.	Bridge Tournament—Holiday Inn

Tuesday, May 14

7:30 A.M.	Committee Breakfasts—Kahler Hotel
8:45 A.M.	Registration at Mayo Civic Auditorium— Exhibits open 8:45 a.m. to 5:00 p.m.
9:00 A.M.	Morning scientific session begins—Mayo Civic Auditorium
12:15 P.M.	Round Table Luncheons—Kahler Hotel
2:00 P.M.	Afternoon scientific session begins—Mayo Civic Auditorium
7:00 P.M.	Annual Banquet—Kahler Hotel—Preceded by reception at 6:00 p.m.

Wednesday, May 15

7:30 A.M.	Committee Breakfasts—Kahler Hotel
8:45 A.M.	Registration at Mayo Civic Auditorium— Exhibits open 8:45 a.m. to 12:00 p.m.
9:00 A.M.	Morning scientific session begins—Mayo Civic Auditorium
	End of meeting—12:00 p.m.

indicated that this year's scientific and technical exhibits in the Mayo Civic Auditorium will be particularly outstanding. Ample time will be provided before and between scientific sessions to view these fine exhibits.

The committee expresses the hope that physicians will make a point of indicating their appreciation to the technical exhibitors whose participation continues to help make the splendid scientific sessions possible.

Heart, Blood, Bones, Shock, Sex

The new "in depth" scientific program format promises to appeal to all physicians, regardless of medical specialty.

Major topics selected for presentation during the two and one half day scientific program include Heart, Blood, Bones, Shock and Sex. Program participants will include outstanding Minnesota physicians as well as a number of visiting experts. All scientific sessions will be at 9:00 A.M., and will be held in the Mayo Civic Auditorium. A listing of scientific sessions and participants appears at the close of this article. For more details, physicians are urged to consult the official Minnesota State Medical Association Annual Meeting program, which will be mailed to the membership.

Round Table Luncheons

A provocative and informative series of Round Table Luncheons have been scheduled for 12:15 P.M. Monday and Tuesday. Round Table Luncheons scheduled for Monday are:

1. "Moral Implications of Heart Transplants"
   Norman E. Shumway, M.D.
   Palo Alto, California
2. "Innovations in Regional Blocks of the Upper Extremity"
   Van S. Lawrence, M.D., Rochester
3. "Diagnostic Aids in the Evaluation of the Hemolytic Anemias"
   Harry Jacob, M.D.
   Boston, Mass.
4. "An Endoscopic New Look at Gastric Lesions"
   Jack A. Vennes, M.D.
   Minneapolis
5. "The Over-Achiever—Why He Fails"
   Harold R. Martin, M.D. and
   Wendell M. Swenson, Ph.D.
   Rochester
6. "Treatment and Consideration of Plantar Warts"
   Robert R. Kierland, M.D.
   Rochester
7. "Risks of Treatment—Medical and Legal"
   Mr. Curtis D. Forslund
   Minneapolis

Topics scheduled for discussion at the Tuesday Round Table Luncheons include:

1. "To Tell or Not to Tell"
   Rev. Dr. Paul B. McCleave
   Chicago
2. "General Anesthesia in the Traumatized Patient"
   Joseph J. Buckley, M.D.
   University of Minnesota
3. "Transplants—The Surgeon's Philosophy"
   John S. Najarian, M.D.
   University of Minnesota
4. "Family Practice"
   Richard V. Ebert, M.D.
   University of Minnesota
   Benjamin F. Fuller, M.D.
   University of Minnesota
5. "Learning Difficulties in Children"
   John S. Pearson, Clinical Psychologist
   Rochester
   Mrs. Jean S. Osman
   Rochester
6. "The Keogh Bill—Fact and Fancy"
   Mr. Jule M. Hannaford
   Minneapolis

Annual Banquet

Seventeen Minnesota physicians who have practiced medicine for 50 years will be honored at the Annual Banquet Tuesday, May 14, at 7:00 P.M. at the Kahler Hotel. The Annual Banquet will be preceded at 6:00 P.M. by the President's Reception.

The Southern Minnesota Medical Association will present its annual medal award at the banquet to the physician who has prepared the outstanding scientific exhibit. In addition, the 1968 recipient of the distinguished service award will be announced. Banquet guests are cordially invited to remain for an evening of outstanding entertainment, including a floor show and dancing. The price of the banquet ticket also includes a late evening buffet.

The annual Bridge Tournament will be held Monday, May 13, in the Holiday Inn.

Pre-Registration

Pre-register for the meeting in Rochester. By completing the registration card enclosed with the monthly Newspage and returning it to the State Office before May 5, physicians can be certain that their badge will be waiting for them at the advance registration desk in the Mayo Civic Auditorium.

Seeing Snakes

Perhaps the most lurid experience that I can remember in the transferring of patients is the time I had a delirium tremens case, with four policemen strategically placed so that the lithe wriggling patient could not escape through any of the apertures of the ambulance which had no doors to close the patient in. All the way to Bellevue I caught "snakes" with him. Poor devil, he saw them on the floor, the sides of the bus, under the blankets, everywhere, crawling and hissing at him. Many of the cases were quite prosaic: old people with chronic illnesses, tuberculosis patients, people recovering from fractures, vagrants, and the like. It was heavy, gruelling work at that time but I would not have had it otherwise, for this intimate daily and nightly contact with the old Bellevue brought me closer to the very heartbeat of my native city.*

*Emily Barringer, M.D.: Memoirs of A Lady Ambulance Surgeon, Bowery to Bellevue, 1950.

I would rather that the people should wonder why I wasn't President than why I am.—Salmon P. Chase

---

He and I have been dead these two years, but we don't choose to have it known.
—Lord Chesterfield

NORTHLANDS REGIONAL MEDICAL PROGRAM

REGIONAL PROGRAM FOR HEART DISEASE, CANCER AND STROKE

The social revolution of our time now focuses on the delivery of health services. "Creative federalism" is not new. It has expanded steadily with the increasing demands of a progressively more advanced and more complicated society. Focuses on employment, agriculture, and rural electrification in the 1930's progressed onward through welfare, education, research and hospital construction. Current involvement in the delivery of medical care began with several fundamental pronouncements:

(1) Medical care is no longer either a personal privilege or a public charity. It is a fundamental human right of all citizens.

(2) Every patient should receive all of the benefits of the latest scientific knowledge.

(3) Each state, each region and each sub-regional area should develop a system of effective health planning.

The Regional Medical Program Act comprises a part of the social revolution in Medicine. In many ways this program simulates the federal agricultural program started over 35 years ago. Recognizing the eventual magnitude of change this program might create, Congress specified an initial phase of planning and development, to last from a few months to several years.

The Northlands Regional Medical Program planning grant was awarded January 1, 1967. We are now in the second year of this planning phase.

What has been accomplished in the fifteen months?

(1) The program organized an extensive involvement of medical centers, professional organizations, health agencies, and health care personnel on a cooperative basis.

(2) Working committees containing many capable and respected physicians, administrators, paramedical and lay personnel have spent literally hundreds of hours developing the program.

(3) A series of basic studies necessary for effective planning and implementation have been instigated. Those most completely developed are as follows:

(a) Development of a Minnesota Health Personnel Databook.

(b) A survey of continuing medical education of physicians.

(c) An evaluation of the TV series "Monday for Medicine."

(d) A plan for a state-wide program for intensive coronary care units.

(e) A rural health care study analyzing three component aspects.

(f) A study for postgraduate education in pediatric cardiology.

(g) A survey of existing and potential resources relating to the care of patients with stroke.

(h) A study to determine feasibility of collecting data and integrating care of pediatric solid tumor patients.

(i) A study of telephonic transmission of computer analysis of multi-channel electrocardiograms.

(j) A computer analysis of the care and results of coronary artery disease.

(k) A study of changing food habits and serum cholesterol levels in free living families.

The Northlands Regional Medical Program is a program developed by the people of Minnesota for the people of Minnesota. Principal medical centers and other organizations have become involved. We need to develop interest and participation in areas distant from the metropolitan center. We solicit your suggestions for appropriate projects in the various sub-regional areas of the state.

Winston R. Miller, M.D., F.A.C.P.
Program Director

John Hunter—Resurrectionist

For years he practically haunted the Irish giant, Byrne (born O'Brien) whose eight-foot skeleton he coveted. The poor man desperately tried to evade him, but every time Hunter managed to track him down. Byrne willed that when he died his body should be placed in a lead coffin, taken out to sea and sunk; at his death the body was placed under heavy guard. Hunter found out when the men on duty had gone off for a drink. He went to the tavern and bribed them with five hundred pounds which he had to borrow, and was able to arrange for the removal of the corpse in a hackney-coach. It was then transferred to his own carriage and taken to Earl's Court. He sectioned the body, removed the flesh by boiling in a huge vat, and reassembled the skeleton, which later hung in his study. In the portrait Joshua Reynolds painted of Hunter, the dangling legs of the giant can be seen in the background.*

Salutation to the Dawn*

Look to this day, for it is life. The very life of life.
In its brief course lie all the verities
And all the realities of your existence.
The bliss of growth. The glory of action. The splendor of beauty.
For yesterday is but a dream. And tomorrow is only a vision.
But this day well lived makes every yesterday a dream of happiness
And every tomorrow a vision of hope.
Look well, therefore, to this day.
Such is the salutation to the dawn.—Kalidasa

*Originally written in Sanskrit by Kalidasa, a Hindu poet and dramatist. Most literary historians agree that it was written in about the third century. Kalidasa was known as the Shakespeare of India. Contributed by Doctors Vernon D. E. Smith, Gerhard E. Knutson, and Neil M. Palm, St. Paul.

Physician's Diary

Bust rather than rust.—Forbes Epigrams

Dr. Robert W. Hollenhorst, Professor of Ophthalmology, Mayo Graduate School of Medicine, has been elected as a member of the Board of Examiners of the American Board of Ophthalmology.

Dr. Michael D. Levitt, instructor at Boston University Medical Center, has been appointed assistant professor of medicine in the gastrointestinal unit of the department of medicine, University of Minnesota.

Hairy sites where creams and ointments do not spread or penetrate readily.
Exposed areas where cosmetic considerations are important.

An invisible topical

for many dermatologic problems

Moist or intertriginous areas where drying action is desirable.

See last page for contraindications, precautions and side effects.

Structurally unique topical steroid in propylene glycol vehicle produces rapid response in many dermatoses.

Synalar Solution produces rapid antiinflammatory, antipruritic action through its unique topical corticosteroid, fluocinolone acetonide. The propylene glycol vehicle provides additional benefits for therapy at problem sites where it is difficult to achieve contact between the lesion and medication – or where creams or ointments may make the lesions worse. Synalar Solution has proved particularly valuable in the symptomatic treatment of seborrheic dermatitis of the scalp, nasolabial folds, eyebrows, ears, and in flexural folds such as the axillae, inframammary, umbilical and anocrural areas. It has also been reported to achieve excellent results in the adjunctive management of atopic dermatitis, contact dermatitis, neurodermatitis, nummular eczema, psoriasis, and sweat retention syndromes in these problem sites.

Penetrates the hairy sites.

In many areas of the body, hair gets in the way of treating the underlying dermatitis. The propylene glycol vehicle of Synalar Solution permits penetration and dispersion at sites where creams and ointments do not readily penetrate. May be applied without matting of hair.

Ideal for moist or intertriginous areas.

Propylene glycol is strongly hygroscopic and is especially useful where sweat retention is a problem. Its low surface tension permits easy spreadability in difficult-to-treat body areas. A number of studies have also shown that propylene glycol has inherent antimicrobial activity.

Cosmetically acceptable for exposed areas.

The propylene glycol vehicle of Synalar Solution possesses many useful cosmetic properties. Clear and greaseless, it is not sticky or messy, will not stain clothing or skin.
In exposed areas of the body where cosmetic appeal is important, Synalar Solution shows nothing but results.

Economical—a little goes a long way.

Because of the properties of propylene glycol and the milligram potency of fluocinolone acetonide, a small quantity of Synalar Solution goes a long way. Also, the prescription price of a 20 cc. plastic squeeze bottle of Synalar Solution is surprisingly low. Thus, your patients obtain economy with the proved efficacy of a potent, truly advanced topical corticosteroid.

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components.

Precautions: In some patients with dry lesions, the solution may increase dryness, scaling, or itching. Application to denuded or fissured areas, such as genital or perianal sites, may produce a burning or stinging sensation. If this persists and dermatitis does not improve, discontinue medication. Although propylene glycol has antiseptic activity, there should be careful initial evaluation and follow-up of infected sites. Incomplete response or exacerbation of lesions may be due to true infection, which requires susceptibility testing and appropriate therapy. On the other hand, saprophytic or low grade infections may clear spontaneously under the influence of Synalar Solution alone. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time.

Side Effects: Side effects are not encountered ordinarily with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions.

Availability: Synalar (fluocinolone acetonide) Solution 0.01% in a propylene glycol vehicle with citric acid as preservative. 20 and 60 cc. plastic squeeze bottles. *Also available:* Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

Salary negotiable, with an association leading to early partnership opportunity. Write: Minnesota Medicine—403, 375 Jackson Street, St. Paul 55101.

Minnesota Medicine at a Glance

Bronchodilator Solution Postoperative—*Ratelle et al.* Page 605

Any procedure or medication that would be useful in speeding the recovery of a patient from anesthesia should also be worthwhile in aiding in a surgical recovery. The studies of Ratelle et al. indicate that the use of a bronchodilator solution was effective in this regard.

The Cytologic Evaluation of Early Pregnancy—*Adcock* Page 611

Vaginal smears taken during pregnancy in threatened and habitual abortion are of prognostic value and identify those pregnancies in which hormonal therapy may be indicated. Vaginal smears are readily obtained, relatively inexpensive, can be repeated frequently and are available with little delay.

Hormones produced by the corpus luteum and the placenta during pregnancy affect the maturation and exfoliation of vaginal epithelial cells. Thus vaginal smears reflect the hormonal background of the pregnancy.

Hyponatremia—*Segar and Moore* Page 625

In recent years, an interesting syndrome, that of hyponatremia associated with excessive renal losses of sodium, has been linked with certain cases of bronchogenic carcinoma. Patients with this disorder fail to curtail thirst despite a diminished urinary volume, which results in an expanded extracellular water volume. In addition, renal sodium excretion is excessive, despite low serum sodium concentrations. A resume of investigations in the aspects of this phenomenon is presented.

Chondrosarcoma of the Sternum—*Larson et al.* Page 679

Tumors of the sternum, either benign or malignant, are fortunately rare. When encountered, however, they can be effectively managed by currently available surgical techniques. The authors present a case and also a description of the surgical procedure required to reconstruct chest wall continuity. En-bloc excision and chest wall reconstruction, tailored to meet the individual requirements of these specific patients, are the essentials of successful management of tumors of the sternum.

To cure is the voice of the past; to prevent, the divine whisper of today.—Kate Douglas Wiggin

Dilantin®
(diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anticonvulsant drugs.
PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. ADVERSE REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred.
DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.
Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

PARKE-DAVIS 015R67

■ to help restore and stabilize the intestinal flora

■ for fever blisters and canker sores of herpetic origin

LACTINEX contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

First introduced to help restore the flora of the intestinal tract in infants and adults,[1, 2, 3, 4] LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.[5, 6, 7, 8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

Salt used to be an all or nothing proposition. Now, there's a happy compromise.

When you tell your patients to cut down on sodium, they have to settle for less than tasty meals. That takes a lot of will power. Now there's new Morton Half/Salt Mixture™. It contains half the sodium of regular salt so your patients can cut down on salt without cutting it out. But, they still get all the satisfaction of true salt flavor. You'll find that new Morton Half/Salt Mixture is far more dependable than will power. And, it makes low-sodium diets a lot easier for your patients to swallow.

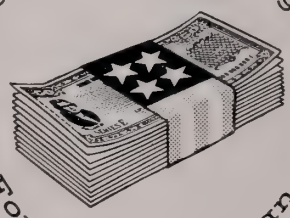
After the picnic even Gramps Was a victim of intestinal cramps

Parepectolin for quick relief of acute diarrhea
...soothes colicky pain with paregoric*
...consolidates fluid stools with pectin
...adsorbs irritants with kaolin,
and protects intestinal mucosa

In elderly patients it is particularly important to stop the diarrhea fast. Parepectolin helps you control diarrhea promptly and gain the patient's confidence until etiology has been determined.



Parepectolin®

Each fluid ounce of creamy white suspension contains:
*Paregoric (equivalent) ..... (1.0 dram) 3.7 ml.
Contains opium (¼ grain) 15 mg. per fluid ounce.
warning: may be habit forming
Pectin ..... (2½ grains) 162 mg.
Kaolin (specially purified) .... (85 grains) 5.5 Gm.
(alcohol 0.69%)
Usual Adult Dose: One or two tablespoonfuls three times daily.

Is it depression?
He says "It's my stomach..."

...but his other symptoms:
functional somatic complaints, anxiety, insomnia, anorexia, feelings of guilt strongly suggest an underlying depression.

when the diagnosis is depression

ELAVIL® HCl
AMITRIPTYLINE HCl

Indications: Mental depression and mild anxiety accompanying depression.

Contraindications: Glaucoma and predisposition to urinary retention. Not recommended in pregnancy.

Precautions and Side Effects: Drowsiness may occur within the first few days of therapy. Patients should be warned against driving a car or operating machinery or appliances requiring alert attention. When depression is accompanied by anxiety or agitation too severe to be controlled by ELAVIL HCl alone, a phenothiazine tranquilizer may be given concomitantly. Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having varying modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Monoamine oxidase inhibitor drugs may potentiate other drugs and such potentiation may even cause death; permit at least two weeks to elapse between administration of two agents; in such patients, initiate therapy with ELAVIL HCl cautiously with gradual increase in dosage required to obtain a satisfactory response. Caution patients about errors of judgment due to change in mood, and that the response to alcohol may be potentiated. May provoke mania or hypomania in manic-depressive patients.

Side effects include drowsiness; dizziness; nausea; excitement; hypotension; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of schizophrenia which may require phenothiazine tranquilizer therapy; epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration or, rarely, transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of the mouth, blurring of vision, urinary retention, constipation; paralytic ileus; jaundice; agranulocytosis.

Careful observation of all patients is recommended. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Supplied: Tablets ELAVIL HCl, containing 10 mg., 25 mg., and 50 mg. amitriptyline HCl, bottles of 100 and 1000; Injection ELAVIL HCl, in 10-cc. vials, containing per cc.: 10 mg. amitriptyline HCl, 44 mg. dextrose, 1.5 mg. methylparaben, and 0.2 mg. propylparaben.

Before prescribing or administering, read product circular with package or available on request.

WHERE TODAY'S THEORY IS TOMORROW'S THERAPY

President's Letter

Academic Medicine

SINCE THE TURN of the century there has been a gradually increasing number of men turning to what is called Academic Medicine, and the tendency is to separate these men from those in the Practice of Medicine.

In this country men of such caliber as Halsted, Osler, Kelly and Welch were of the early group of full-time professors of Surgery, Medicine, Gynecology, and Pathology; and under their impetus others were trained specifically to become full-time teachers. Some of Halsted's men remained in training for seven to ten years and then went to occupy full-time teaching posts.

In the last twenty years, particularly under the influence of Doctor Wangensteen, the increase in the full-time Academic Surgeon has been fantastic; young men enter training with the idea that they will stay in Academic surroundings for the full course of their career, becoming highly trained, not only in the practice of surgery but also in research.

This increase of Academics has led to some misunderstanding with those in practice and vice versa, neither side fully comprehending the problems of the other.

In the 1920s many of the Chairs of Medicine and Surgery were held by part-time men, the Clinical Professors, whose main concern was the training of clinical men with little time for or knowledge of research. It is true that many fine surgeons have evolved under this system; however, as medicine and surgery developed rapidly the clinical professor became more frustrated. He was unable to keep up with, let alone get ahead of the tremendous growth of knowledge, and at the same time was unable to give proper attention to his ever increasing patient load. He found it difficult to be both fish and fowl, but had to choose between them.

There are many frustrations for the man who chooses an Academic career, such as some loss of independence, interdepartmental skirmishes, decline in income, administrative responsibilities, and less personal rapport with patients. However, he does have the advantages of more time for reading and research, ease of consultation, the protection of the institution, and the satisfaction of developing young men to become highly qualified practitioners or teachers of medicine or surgery in their own right.

The Practitioner also has many advantages, such as a larger income, greater independence, freedom of movement, a more personal relationship with his patients. However, his disadvantages consist of full responsibility for his patients and too little time to support and sustain a large patient load.

There has developed a third type of doctor:

The Evaluation and Treatment of Hydrocephalus

DONLIN M. LONG, M.D.*
SHELLEY N. CHOU, M.D.*
LYLE A. FRENCH, M.D.*
Minneapolis, Minnesota

THE SERIOUS PROGNOSIS of untreated hydrocephalus is now thoroughly documented and the need for prompt evaluation and surgical therapy is well accepted.[20] Laurence has reported upon the natural history of hydrocephalus and recorded a 46 per cent mortality in untreated cases. Of the survivors, only 18 per cent had I.Q.s greater than 85.[9,10] Foltz and Shurtleff reported even less optimistic statistics. Only 22 per cent of their patients survived for five years without surgical therapy, and of the untreated cases, only 5.5 per cent had I.Q.s of 75 or higher.[6]

Over the years a variety of operations have been devised for the control of hydrocephalus. Each has had its enthusiasts; but in general, salvage rates of less than 50 per cent have been reported. In 1952 Nulsen and Spitz introduced a unidirectional ventriculo-atrial shunt.[14] This technique of shunting excess spinal fluid from the cerebral ventricles to the vascular compartment has proved of great value and has become the standard method for the treatment of hydrocephalus. Many modifications of the original system are in use, but the basic principle remains the same.

The ventriculo-atrial shunt has now been in use long enough to permit assessment of its value for control of hydrocephalus and to allow comparisons with the results of other procedures. This review of 230 patients operated upon at the University of Minnesota Hospitals from January 1, 1938, to July 1, 1967, has been made to provide an accurate evaluation of the results of the various kinds of operative procedures undertaken in the treatment of hydrocephalus. Special emphasis has been placed upon the 93 patients treated since 1961 in whom some type of ventriculo-atrial shunt was employed as the primary therapy for hydrocephalus.

Methods

This investigation is based upon 230 patients

*Department of Surgery, Division of Neurosurgery, University of Minnesota Medical School.

with hydrocephalus, 87 of whom were treated between 1938 and 1951 and have been previously reviewed by Haines.[7] Between 1938 and 1960 a variety of operative procedures were utilized; from 1960 until the present time the ventriculo-atrial shunt has been employed primarily for the control of hydrocephalus.

The patients were all treated at the University of Minnesota Hospitals and were initially evaluated on either the Pediatric or the Neurosurgical Services. The standard evaluation consisted of complete historical and general physical examinations and complete neurological examinations. Head circumferences were obtained on a serial basis. Roentgenograms of the chest and skull, hemogram and urinalysis were also obtained.

The majority of the patients had subdural taps, communication studies and an air study of some type prior to operation.

Most of the patients with associated meningocele* or encephalocele underwent definitive repair prior to a shunt procedure; operative procedures for the correction of orthopedic, urologic and other defects were undertaken when indicated.

Nearly all operative procedures were performed under general anesthesia. The procedures themselves were standardized and followed the accepted techniques described in the literature (Table 2). After operation the patients were followed on a regular basis and evaluated in the Neurosurgical Clinic. Regular measurements of head size and estimates of functional capacity as well as neurological status were made. No formal psychometrics were obtained. The average follow-up in those cases with ventriculo-atrial shunts was 32 months, with the longest follow-up period being eight years.

The standard ventriculo-atrial shunt was the Pudenz-Heyer medium pressure valve. As soon as it became available, a flushing device was incorporated into this system and has been a part of the shunt procedure since 1961. A small number of Holter valves were utilized as well.

*See Test Your Word Score Page 797.

TABLE 1

Cause or Type of Hydrocephalus—1951 to Present

Communicating, cause?	32
Noncommunicating, cause?	19
Myelomeningocele	34
Encephalocele	10
Meningitis	14
Other congenital defect	17
Unknown or other	17
	143

TABLE 2

Operations for Hydrocephalus

	Number	Mortality
Choroid plexus coagulation	34	9.4%
Third ventriculostomy	21	33.0%
Lumbar-peritoneal	11	.....
Ventriculo-peritoneal	4	.....
Ventriculo-mastoid	20	14.3%
Other	13	15.0%
More than one	10	.....
Ventriculo-atrial	81	7.0%
Ventriculo-atrial + other	12	.....

Findings

Types of Hydrocephalus

The majority of the hydrocephalics were of the noncommunicating variety; the single most common cause of hydrocephalus was the Arnold-Chiari malformation associated with a myelomeningocele (Table 1).

Operative Procedures

In the 87 patients operated upon in the period from 1938 to 1951, 119 operations were performed (Table 2). In the original evaluation by Haines, 35.2 per cent of these patients were found to have adequate control of hydrocephalus and 43.2 per cent were found to have normal mentality.[7] Only a small percentage of these patients were available for long-term follow-up, but 10 were judged to have been normal for periods ranging from six to 19 years.

Mortality

It is interesting to note that third ventriculostomy and exploration of the posterior fossa with lysis of adhesions were associated with a 33 per cent mortality rate, which is consistent with the mortality published in other series (Table 2). Choroid plexus coagulation had only a 9.4 per cent mortality; but its control of hydrocephalus was felt to be adequate in only 37.5 per cent of cases. While quite effective in tumor cases in which a 65.7 per cent control of increase in intracranial pressure was obtained, the Torkildsen procedure, a shunting of fluid

from the ventricular system to the cisterna magna, was effective in only 18.2 per cent of nontumor cases of hydrocephalus.

In the 81 cases of ventriculo-atrial shunts which were not unusually complicated or did not also have choroid plexus coagulation, 118 operations were performed, an average of 1.5 operations per patient. In the nine cases which were considered unusually complicated, 59 operations were performed, a total of 6.6 per patient. Of these, 25 were ventriculo-atrial shunts: an average of 2.8 ventriculo-atrial shunts per patient. In the cases which had choroid plexus coagulation in addition to the ventriculo-atrial shunt, 16 operations were performed, an average of 5.3 operations per patient; five of these were ventriculo-atrial shunts or 1.5 shunts per patient.

Results of Operation

Results in this group are somewhat difficult to evaluate in the absence of formal psychometric and intelligence testing and because of the young age of many of these patients. For this reason, rather large groups have been used for classification purposes (Table 3). The patients were said to be functional mentally if they were competing with their peers in school or in other intellectual endeavors, or if it was the impression of parents and examining staff physicians that they were at a competitive level. If they were able to compete but were thought to be significantly less adequate than their peers, they were judged to be slightly retarded. It is probable that there is overlap between these two groups. Those who were noncompetitive were classified as seriously retarded.

Fifty-one per cent of these patients were considered to be functioning normally; an additional 16 per cent were thought to be slightly retarded. Combining these two groups provides a figure of 67 per cent who were functional from an intellectual standpoint. This evaluation does not include other neurological deficits. Twenty per cent of the patients were judged to be very retarded and 6 per cent had died. Most of these deaths occurred in patients with myelomeningoceles and were secondary to chronic urinary problems. The operative mortality was 7 per cent, a figure which will be explored in more detail in another part of this report.

TABLE 3
Results of Operation

	functional	severely retarded	dead
Ventriculo-atrial Ventriculo-atrial + Other	67%	20%	6%
All other operations			
1938-1951	35.2%	....	....
1951-1960	32%	33%	7%

In those patients undergoing operations other than ventriculo-atrial shunts, there were 96 operations in 46 patients, an average of 2.1 per patient. Twelve of these patients were judged to be normal and three to be slightly retarded, giving an overall competitive rate of 32.7 per cent. Fifteen patients were felt to be seriously retarded. Three expired due to nonoperative causes. The operative mortality in this group was 15 per cent (seven patients) and the follow-up was thought to be inadequate to make an evaluation in six patients.

Complications

Infection

The overall infection rate including both major and minor infections was 14 per cent. The infection rate in otherwise uncomplicated patients was 8.5 per cent; while in those patients considered unusually complicated, undergoing multiple operative procedures, the infection rate was 31 per cent. It must be emphasized that this infection rate does not represent primary infections. No attempt has been made to separate those cases which were complicated upon arrival at the University of Minnesota Hospitals or which had suffered previous infections or complications in other operative procedures performed prior to admission. Of the 10 operative infections occurring in the 81 otherwise uncomplicated cases, six followed postoperative cerebrospinal fluid fistulae secondary to inadequate shunt function. Thus in those cases without previous infection with adequately functioning ventriculo-atrial shunts postoperatively, the overall infection rate was only 4.9 per cent.

In addition to infections definitely related to the operative procedure, there were additional cases[11,19] in which the valve became infected during an episode of supposed septicemia secondary to urinary tract infection, pneumonia

or other upper respiratory infections.

Obstruction of the Catheter

Obstructions of the ventricular end of the catheter are usually secondary to envelopment by the choroid plexus or obstruction of the catheter lumen with detritus. This occurred 23 times in this series of cases. Obstruction of the atrial end of the catheter is usually secondary to thrombosis in the superior vena cava and is frequently the result of growth of the patient with gradual elevation of the atrial catheter into the superior vena cava or jugular vein. This occurred 18 times in this series. There were no cases of serious thromboembolic phenomena from venous or cardiac thrombosis. There were three instances in which an atrial catheter became disrupted and a portion of the catheter embolized to the right heart.[11] There were 12 cases in which some portion of the equipment was felt to be structurally incompetent, resulting in disruption of the shunting system. In three instances the valves inserted developed a malfunction and had to be replaced.

End Results

The overall results may then be summarized as follows: of 93 patients in whom some form of ventriculo-atrial shunting was employed as the primary treatment of hydrocephalus, 67 per cent were found to be competitive, 20 per cent were found to be very retarded, 6 per cent succumbed in the course of their illness due to nonoperative causes, and the operative mortality was 7 per cent. In two series of patients from this Clinic who were treated with operations other than the ventriculo-atrial shunt, the success rate varied from 33 to 42 per cent. The operative mortalities were 15 and 33 per cent in the two series.

Discussion

This entity appears to have been known since ancient times[7,18] and was clearly described by Vesalius in the sixteenth century. However, even after the classic papers of Key and Retzius demonstrating the circulation of the cerebrospinal fluid, the pathophysiological condition underlying hydrocephalus was thought by most authors to be meningeal hydrops.[7] It remained for Dandy and Blackfan to provide conclusive evidence that obstruction of the circulation or absorption of cerebrospinal fluid was responsible for hydrocephalus.[2] The process of cerebrospinal fluid production by the choroid plexus and circulation through the ventricles into the lumbar and cranial subarachnoid spaces with the eventual absorption in the cranial arachnoid villi was formulated in its modern form by Weed in 1917 and has been modified only slightly since that time.[21,22]

Shunt to Basal Cisterns

Shortly after Dandy's experimental work on this subject, several operations for the control of hydrocephalus were devised. Of these third ventriculostomy and choroid plexus coagulation have been most utilized. Third ventriculostomy consists of puncture of the lamina terminalis above the optic chiasm and/or puncture of the floor of the third ventricle as well, thus allowing the fluid contained within the obstructed ventricular system to escape into the basal cisterns and so circulate throughout the subarachnoid spaces.[3,4,5] Unilateral or bilateral endoscopic coagulation of the choroid plexus of the lateral ventricle was also used extensively before the introduction of the ventriculo-atrial shunt.[16] But the favorable results of choroid plexus coagulation and third ventriculostomy[18] have not been substantiated by other series, including our own. Lumbar-ureteral and ventriculo-ureteral shunts have proved successful in selected cases;[7] however, the number of candidates for the procedure in any group of hydrocephalics is not large and these operations have not been employed in our patients.

Shunt to Nonvascular Compartments

Attempts have been made to shunt spinal fluid to a variety of spaces besides the vascular compartment. Shunts into the subcutaneous tissue and into the marrow space have not proved successful.[7] In communicating hydrocephalus lumbar-subarachnoid to peritoneal cavity, shunts have proven effective in some instances; however, in our hands the shunts from ventricle to peritoneal cavity have not been successful for more than a few months because of loculation of fluid with adhesions and failure of absorption by the peritoneum. A few individuals have reported more success with this method. Ventriculo-pleural shunts have also been employed, but formation of adhesions from pleura to lung and failure of absorption

in this space have occurred with considerable frequency.[8] We now do not routinely employ these shunts in the primary treatment of hydrocephalus, though they may be of value in selected cases complicated by infection or as a temporizing measure when a vascular shunt is contraindicated for some reason. Ventriculomastoid shunts have been created but have commonly resulted in infection.[13] We have successfully used a ventriculo-sagittal sinus shunt in several adults with malignant brain tumors but have not employed this technique in children. Recently, a direct ventriculo-atrial shunt has been described, which requires thoracotomy and placement of the atrial catheter by cardiotomy; but it remains to be seen whether improved results will justify the use of an operation of this magnitude.

The Shunt Tubing

Early attempts at creating ventriculo-vascular shunts were confounded by the lack of an adequate shunt-tubing material. Finally in 1952 Nulson and Spitz introduced the Holter valve which consisted of unvalved ventricular and atrial catheters connected by a ball valve pumping device.[14] The standard method for the insertion of this shunt was described at that time. The ventricular catheter is placed preferably in the frontal horn of the lateral ventricle through a small parietal burr hole and connected to a subcutaneously placed pumping device over the mastoid region. The atrial catheter is placed in the right jugular vein, threaded down to the level of the mid-right atrium, and connected subcutaneously to the pumping device. In 1957 Pudenz and Sheldon introduced the Heyer valve which consisted of a straight ventricular catheter attached to a vascular catheter with a slit valve located at the intra-atrial end.[15] Again, this shunt was from right lateral ventricle subcutaneously into the right jugular vein and then into the heart. Later a flushing device or pump was included in the Pudenz system so that the function of the shunting system could be checked. Many modifications of these basic types have now been made and several systems are now available, but the method of insertion and the functional principles remain the same.

Evaluation of Suspected Hydrocephalus

As a result of our experience to date, we have now come to utilize a more or less standard evaluation procedure for the suspected hydrocephalic. In addition to routine historical and physical examination, a complete neurological examination and skull films are obtained. Bilateral subdural taps are performed to exclude the possibility of subdural hematoma. Following the subdural taps, 1 cc. of dilute Evan's Blue is injected into the right lateral ventricle. Fluid is then removed from the left lateral ventricle to be sure there is circulation from right to left. A lumbar puncture is performed and small amounts of fluid serially removed to determine if communication from ventricle to lumbar-subarachnoid space occurs. If no communication is present in 15 minutes the case is judged to be functionally noncommunicating. Recently we have been utilizing the intrathecal administration of a radioactive technetium-albumin complex and following the migration of this protein complex by serial scintillation scans, which provides a much more dynamic analysis of circulation of the spinal fluid. Following the communication study a limited ventriculogram is performed and, if it seems indicated, lumbar pneumoencephalography may also be utilized. In a few cases positive contrast ventriculography is necessary to delineate the process. As soon as the air is absorbed, a right ventriculo-atrial shunt is performed. It is now our practice to insert the ventricular catheter through a parietal burr hole and to place the tip at about the level of the coronal suture in order to avoid the choroid plexus. The pump or flushing device is placed behind the right ear in the burr hole, and the atrial catheter introduced into the jugular vein through a branch of the common facial vein with the tip of the atrial catheter placed in the mid-right atrium. We prefer to place this atrial catheter under x-ray control, though other methods using electrocardiogram and pressure wave changes have been described. Postoperatively there is no need to pump the shunting system, for it will function spontaneously, being constructed to flow at a specific pressure and to remain closed at all lower pressures.

Postoperative Evaluation

Patients are followed subsequently at regular intervals in the outpatient clinic. These

visits include measurement of head size and check of valve function. It is most important to be assured that the valve is functioning, and it is also important to follow the head growth curve. If the shunting procedure has been successful the head growth should cease until the head circumference has returned to the normal range for the patient's age and size. Head growth may then continue, but at the normal rate. If the head circumference remains outside the normal range and slow head growth continues, it may mean that the shunting system is inadequate. We also consider it most important for these children to receive prophylactic antibiotics if they have intercurrent infections. The urinary tract infections to which the myelomeningocele paraplegics are prone must be treated promptly. It is our usual practice to administer antibiotics to shunt patients in the course of viral or upper respiratory diseases as well.

Choice of Operative Procedure

As a result of this study we believe several statements can be made concerning the treatment of hydrocephalus. It seems unequivocal that the successful use of the ventriculo-atrial shunt will provide a higher percentage of functional individuals than the other methods for the treatment of hydrocephalus currently available. It also seems definite that the results of surgical treatment in hydrocephalus are significantly better than hopeful waiting. In our hands third ventriculostomy, choroid plexus coagulation, ventriculopleural, ventricular and/or subarachnoid-peritoneal shunts have not proven as effective as the vascular shunts. This does not mean, however, that these methods cannot be employed to advantage in many instances; indeed, they remain helpful adjuncts in the care of these patients. The mortality and morbidity of the vascular shunting operations are real but not great. Since the institution of these procedures, the infection rate has steadily decreased and the mortality rate is now less than 5 per cent.

Assessment of Functional Recovery

Because of the young age of many of these children and since we do not have formal psychometric evaluations of all of them, it is impossible to completely characterize their functional state. Even accurate measurement of the I.Q. is not always possible in these cases, for it has been shown that there is a marked disparity between verbal and performance intelligence quotients in many of these children.[6] Nevertheless, we feel the judgment of the responsible physician and the parents can be sufficient for the purposes of this communication. How competitive these children will actually be must await reevaluation after a more significant number of them have advanced through school. Nor does this evaluation take into consideration the physical deficits which many of these children suffer. Foltz has indicated that the prognosis for hydrocephalics without significant neurological loss is much better than for those with associated myelomeningocele or other deficits, even when the latter are mentally intact.[6]

What the eventual salvage rate in hydrocephalus may be is still unknown. It is obvious that the ventriculo-atrial shunt is not a panacea for this disease but appears to be definitely superior to no treatment at all and is the most valuable of the multiple procedures in current use.

Summary

(1) A total of 230 patients with hydrocephalus were treated surgically at the University of Minnesota Hospitals from 1938 through 1967. (2) Eighty-one were treated with ventriculo-atrial shunts; 67 per cent of this group are functional individuals. (3) Twelve additional cases were treated with ventriculo-atrial shunts but also underwent multiple shunting procedures and were considered unusually complicated. (4) Twenty-one other combinations of procedures were utilized primarily before 1960. Of these patients only 37 per cent could be considered functional. (5) We have described our current plan for the evaluation and treatment of hydrocephalus.

I do not greatly care whether I have been right or wrong on any point, but I care a good deal about knowing which of the two I have been.—Samuel Butler

Periarteritis Nodosa

Complicated with Bilateral Spontaneous Massive Perirenal Hemorrhage

EARL E. GAMBILL, M.D.*
JAMES H. DE WEERD, M.D.**
MALCOLM B. DOCKERTY, M.D.†
Rochester, Minnesota

PERIARTERITIS NODOSA is a systemic disease that involves the small and medium-sized arteries. It is characterized by an inflammatory reaction that results in necrosis and weakening of the vessel with secondary nodular thickening and fibrosis of the vessel wall, thrombosis, infarction, aneurysmal formation, and hemorrhage. Acute, subacute, and chronic phases may be seen simultaneously in the same organ. The etiology is unknown. However, some work by Rich[1] and by Rich and Gregory[2] lends support to the possibility that the disease might be due to a hypersensitivity reaction. Although the vascular lesions can occur in almost any organ, they reportedly are most commonly found in the kidneys (in about 80% of cases). The incidence of perirenal hematoma due to this disease is rather low, the first case reported with this complication being that of Schmidt[3] in 1908. Up until 1966 we were able to tabulate approximately 30 such cases,[4-12] to which we would like to add another. Bilateral perirenal hematoma due to this disease is rare. Up to 1966 we were able to find reports of four cases,[4,6,8,9] ours making a total of five.

Successful recognition of the microaneurysms within the kidneys by means of selective renal angiography prior to rupture of an aneurysm has been demonstrated by Ostrum and Soder[11] and by Horner and associates.[12]

Report of Case

A 48-year-old male farm worker was admitted to the Mayo Clinic and hospitalized on September 25, 1962, with the complaint of progressive left ear deafness for five months. Eight weeks before admission he had noticed decreased auditory acuity in the right ear associated with the onset of episcleritis in the right eye; this spread to involve the left eye approximately one month before admission. At this time he also noted the onset of a left frontoparietal throbbing pain, worse at night, unassociated with rhinorrhea, lacrimation, or scotomata, and usually relieved by ergotamine with caffeine (Cafergot), belladonna alkaloids, and acetophenetidin (Wigraine), or large doses of salicylates. During the six weeks before

†Mayo Clinic and Mayo Foundation: Section of Surgical Pathology.

admission his weight had dropped from 190 to 160 pounds, and for two weeks before admission he had had intense anorexia, nausea, and occasional vomiting, unrelated to the presence of headaches.

Physical Examination

On physical examination he weighed 160 pounds and had a temperature of 99.2 F, a pulse rate of 75/min, which was regular, and a blood pressure of 128/86 mm Hg. Examination revealed a nerve-type hearing loss. Bilateral episcleritis was present without impaired vision; the optic fundi were normal. The edge of the liver was palpable on inspiration but did not seem enlarged. Moderate pain with tenderness was present over the left temporomandibular joint and over the right heel. The left gastrocnemius muscle was tender to pressure.

Urinalysis, determination of blood hemoglobin and urea, complete serologic examination, and roentgenographic examination of the chest, temporomandibular joints, esophagus, stomach, colon, small intestine, and head did not show any abnormality. A diverticulum was noted in the third portion of the duodenum. The leukocyte count was 9,100/cu mm of blood, with 91% neutrophils. The sedimentation rate was 30 mm in one hour (Westergren method). The flocculation test for rheumatoid factor was weakly reactive and a lupus erythematosus clot test was negative. The value for fasting blood sugar was 93 mg/100 ml. The sulfobromophthalein test for hepatic function showed a retention of 30% at the end of one hour. The bilirubin concentration was 0.5 mg/100 ml of serum direct and 0.7 mg indirect (van den Bergh reaction). The alkaline phosphatase value was 15 units/liter and the serum glutamic-oxalacetic transaminase activity was 0.93 μmole/hr/ml (normal values). Urinary amylase values were normal. Serum protein electrophoresis revealed the following values (gm/100 ml): albumin 3.05, α_1-globulin 0.58, α_2-globulin 0.87, β-globulin 1.02, γ-globulin 2.11, and total protein 7.63.

Hospitalization

During hospitalization the patient had a low-grade fever, his temperature increasing at times to 101 F. His headaches responded partially to the use of vasoconstricting drugs. The episcleritis responded poorly to the topical administration of steroids. Anorexia persisted. After several days, the sulfobromophthalein test showed 40% retention at the end of one hour; thymol turbidity was 3 units, cephalin-cholesterol flocculation negative, alkaline phosphatase 22.8/liter, sedimentation rate 50 mm in one hour, and the Quick prothrombin time 20 seconds. Repeated attempts at transthoracic needle biopsy of the liver revealed striated muscle, fat, and a very tiny fragment of liver tissue not adequate in amount for diagnosis. Repeat needle biopsy of the liver was advised but the patient refused. He was dismissed, being advised to rest at home for six weeks and then to return for further study.

Five days later the patient returned complaining of dull epigastric and right-upper-quadrant aching. Examination disclosed moderate rigidity in the right upper quadrant associated with tenderness. He had grade 3 albuminuria, grade 2 microhematuria, and grade 3 pyuria. The blood leukocyte count was 8,700 with 87% neutrophils. The sedimentation rate was 94 mm in one hour.

Two days after the second admission the patient was awakened from sleep by extremely severe right lower abdominal pain which was referred to the right groin and scrotum and to the right costovertebral angle. Acute right-lower-quadrant tenderness with the rebound phenomenon was present; the right side of the abdomen was rigid and there was marked tenderness to percussion in the right flank. At this time the hemoglobin value was 11.3 gm, the erythrocyte count 4,000,000/cu mm, and the leukocyte count 12,900 with 87% neutrophils. The sedimentation rate was 107 mm in one hour and the blood urea value 54 mg. An excretory urogram suggested the presence of a right renal mass, and subsequently a right retrograde pyelogram demonstrated a collecting system which seemed to be compressed but otherwise normal. Both renal outlines were poorly defined, but comparison of films revealed a definite increase in size of the right renal mass over a span of 72 hours. Further investigation of the indeterminate mass lesion by nephrotomagraphy versus exploratory laparotomy was considered.

Two days later the patient had a sudden recurrence of severe right midabdominal pain with shock and a drop in systolic blood pressure to 50 mm Hg. Exquisite tenderness in the right flank and right midabdomen was noted over a firm, ill-defined mass. The hemoglobin value was 10.4 gm.

An emergency operation on October 21, 1967, disclosed a moderate amount of free serous fluid in the peritoneal cavity. There was considerable edema in the right side of the abdomen, and a hematoma was present in the mesocolon. The gallbladder, stomach, duodenum, liver, pancreas, appendix, and colon were normal. The hematoma occupied most of the right renal region, extending down almost to the pelvic brim and medially as far as the great vessels. Several firm, palpable, subcapsular nodules were felt in the spleen but were not accessible to vision. In nearly the whole length of small bowel there were tiny, firm, discrete subserosal nodules which appeared to be within the lymphatics. One of these was biopsied but not identified by the pathologist. It was necessary to remove the kidney, adrenal, and 15 cm of the right ureter. Pathologic examination of the tissue revealed extensive perirenal hematoma formation, secondary to renal panarteritis with a cortical aneurysm 3 cm in diameter which had ruptured through the renal capsule. The ureter showed periureteral hemorrhage.

Subsequently the patient was given blood transfusions, steroids, and general supportive measures. However, eight days postoperatively he was seized with severe pain in the left flank associated with marked tenseness and tenderness of the left flank and left side of the abdomen. At this time the hemoglobin value dropped to 7.2 gm. It was felt that he had experienced another massive perirenal hemorrhage. Accordingly, the next day the left renal region was exposed and a large hematoma measuring 10 by 15 by 20 cm was identified as probably arising from the kidney inasmuch as the blood was concentrated immediately adjacent to the kidney, especially posteriorly. The capsule had been separated from the kidney over most of the posterior and lateral aspects by the hematoma. In the lateral margin of the lower pole of the kidney

was a defect 2 cm long and 0.5 cm wide filled with organized clot. It was assumed that bleeding with hematoma had resulted from an aneurysm secondary to periarteritis nodosa of the kidney. Renal biopsy for confirmation was considered extremely hazardous and therefore inadvisable. Large mattress sutures were placed and tied firmly over absorbable gelatin sponge (Gelfoam) to discourage further hemorrhage from the defect in the kidney. Convalescence was slow. The patient was dismissed one month postoperatively with instructions to continue on steroid therapy (methylprednisolone [Medrol], 10 mg four times a day).

On November 28, 1962, 11 days after discharge from the hospital, he was readmitted complaining of unusual dyspnea, orthopnea, ankle edema, and a cough productive of pinkish sputum. Roentgenograms of the chest showed a patchy infiltrate extending into the perihilar regions of both lungs, consistent with patchy interstitial hemorrhage. Temporary response to therapeutic measures was followed by gradual increase in cough and dyspnea. There was also recurrence of severe pain in the left lower abdominal quadrant and left flank. Three days later, clinical shock suddenly supervened and the patient died. The clinician felt that death was due to hypokalemia, uremia, and congestive failure.

Autopsy disclosed numerous vascular lesions in the liver and kidney and some in the gallbladder wall typical of panarteritis nodosa (periarteritis nodosa). The testes and adrenals showed hemorrhagic areas but no definite arterial lesions. The myocardium showed some scarring but no definite lesions. Multiple lesions of periarteritis were seen in the kidney.

A Vinegar Cure

On one occasion a man came to Ibn Butlan* in his surgery at Aleppo complaining of hoarseness and complete loss of voice, and stating in reply to enquiries as to his occupation that he was a sifter of earth. Ibn Butlan made him drink half a pint of strong vinegar, whereupon he was seized with vomiting and threw up a quantity of mud with the vinegar, after which his throat was cleared and his speech became normal. Ibn Butlan said to his son and his pupils who were present, "Treat no one with this remedy or you will kill him. As for this man, some of the dust from the sieve had stuck in his gullet and nothing but vinegar could have dislodged it."**

*Ibn Butlan was a notable Arab Christian physician of the second century, A.D.

New Theory

First a new theory is attacked as absurd; then it is admitted to be true, but obvious and insignificant; finally it is seen to be so important that its adversaries claim that they themselves discovered it.—William James

It's the Law

The courts have established that, in a hospital, the physician's order on the patient's chart is a prescription order to dispense by nurse and to administer. In a nursing home, however, the chart order is merely an order to administer; not to dispense. Accordingly, unless the physician writes and signs a separate prescription order or personally transmits the order via telephone, the pharmacist must contact the physician for verification of the chart order. It should also be remembered that the physician's office nurse, as an agent of the physician, can legally transmit such information. The nursing home nurse, on the other hand, is an agent of the nursing home, not the physician, and cannot legally transmit the physician's order to dispense. Hence, the pharmacist's return call to the physician for verification.

The matter of prescription renewal (refill) authorization is one of continuing interprofessional concern. If the physician would indicate, whenever possible, the number of renewals or length of time for renewal authorization, considerable time could be saved by all parties and better patient care would result.

Minnesota State Pharmaceutical Association

Waardenburg's Syndrome

This syndrome includes developmental anomalies of the eyelids, eyebrows, or nose root, pigmentary anomalies of the iris and head hair, and congenital deafness. Waardenburg in 1951 described the syndrome as a distinct entity. He found the anomalies in 12 of 840 deaf mutes. A regular dominant inheritance is the rule. Both sexes transmit these characteristics; in particular, there is father-to-son transmission.

Although the most serious defect in this syndrome is congenital deafness, it is seldom accepted and mentioned by patients. Dystopia canthorum is the most conspicuous feature. This displaced palpebral angle is readily apparent, especially in childhood. Other frequently observed anomalies consist of (1) lateral displacement of the medial canthi and lacrimal points; (2) a hyperplastic, broad, high nasal root; (3) hyperplasia of the medial portions of the eyebrows; (4) partial or total heterochromia iridum; and (5) partial, unilateral circumscribed albinism of the frontal head hair (white forelock). There may be blepharophimosis rather than ptosis, hypoplasia of the carunale and of the plica semilunaris, displacement of the puncta, especially the lower, laterally toward the cornea, and widened interpupillary distance. Occasionally other anomalies may be present, such as limitation of ocular movements, underdevelopment of the orbit, thickening of the tarsus, epicanthus, and such generalized defects as brachycephaly.

Waardenburg expressed the opinion that many of these abnormalities represent a persistence of the normal relationships in the embryo at eight to 10 weeks, so that the syndrome is parallel in nature to the persistence of the embryonic choroidal cleft.

Intravenous Regional Anesthesia*

A New Technique

G. THOMAS WIER, M.D.**
St. Paul, Minnesota

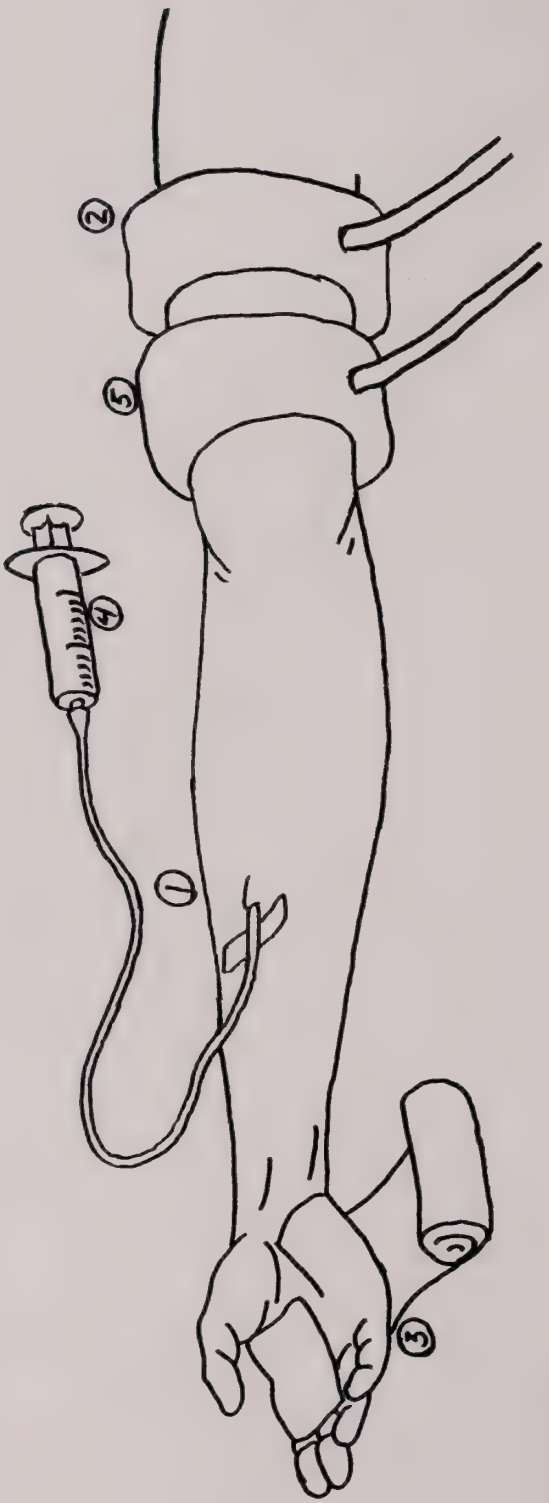
EVER SINCE Bier in 1908[8] and Holmes[9] in 1963 described in the literature the technique for intravenous regional anesthesia, it has been catching on like wildfire in most of the major clinics of this country and Europe. The technique is one that finds its greatest use in the general practice of medicine and surgery rather than in anesthesiology. It is with this thought in mind that I have presented this paper for a group not doing anesthesia full time. The technique is extremely simple and if carried out meticulously, the results approach 100% success.

Technique

Step No. 1.

A needle is carefully placed and anchored in a vein usually as close as possible to the site of surgery, or in the case of fracture, to the site of the injury. I prefer to use a No. 19 gauge Butterfly type needle, but any needle that is likely to stay in place easily will do. It is best to have a short extension of intravenous tubing from the needle to the syringe as this will facilitate wrapping of the arm in a later step.

Step No. 2



The tourniquet is placed on the upper arm as close to the axilla as possible and is connected to a source of pressure which must be adequate to overcome the systolic blood pressure. In isolated instances where this has not been done it has proven to be a serious hazard to the technique of regional anesthesia. The systolic blood pressure should be known before the tourniquet is inflated.

Step No. 3.

The arm is then elevated so that the blood will drain by gravity as a rubber bandage is placed to help squeeze the residual blood from the extremity. After the arm has been completely wrapped with the rubber bandage (Martin or Esmarch) to include even the upper tourniquet, the tourniquet should be in-

*Presented at the Big Mountain Medical Ski Conference January, 1968, in Whitefish, Montana.

**Chief, Department of Anesthesiology, St. Paul-Ramsey Hospital, St. Paul.

Figure

flated to a pressure above the systolic blood pressure. The rubber bandage is then removed and the arm laid down in the position for surgery.

Step No. 4.

At this time a syringe filled with the anesthetic agent is attached to the previously placed intravenous tubing for the purpose of injecting the agent slowly into the now collapsed veins. If at this time the needle should become dislodged from the vein, it is quite difficult to reinsert it in the collapsed vein and the procedure will probably have to be re-started. If the needle remains properly in place, the veins fill slowly. If they do not fill, then an adequate volume of anesthetic solution has not been used to produce acceptable anesthesia for the surgery involved.

The onset of anesthesia should be almost immediate.

Step No. 5.

In this last step, we now put a second tourniquet below the first. This tourniquet is, of course, being placed in an anesthetized area of the arm and when inflated will cause significantly less pain and discomfort than the upper tourniquet. Patients seldom tolerate the tourniquet for much more than 20 or 30 minutes without giving large voice to the complaint of pain involved. For this reason the second tourniquet below the upper one is now inflated and used to produce ischemia to the limb for the remainder of the operation.

Comments

In the recent literature a great deal of work has been done regarding the mode of action of intravenous regional anesthesia and what the long-term effects may be.

Volume and Dosage

Many individuals have been using this technique with different agents and volumes of solution. The general consensus is that it takes about 40 ml. of a solution to give adequate anesthesia in an adult arm and approximately 100 ml.[7] for an adult leg. The only anesthetic agents that seem to cause any degree of difficulty in this technique are 2-chloroprocain because of thrombophlebitis which may be associated with its use;[1] and although this is

not absolute contraindication, the formation of methemoglobin[3] following the use of prilocaine has been postulated as a hazard in the elderly patient for intravenous regional anesthesia.[6] Xylocaine (0.5%) injected in the previously recommended volumes gives adequate anesthesia for nearly all surgical techniques. Occasionally, with this concentration of agent a patient may retain some motor control and probably will feel some bone pain if extensive work is being done on the bones, such as insertion of artificial metacarpal phalangeal joints. To alleviate these problems, a higher concentration of anesthetic agent may be used in anticipated cases, but it must be realized that this also increases the possible toxic effects when the tourniquet is released.

Duration of Anesthesia

Most anesthesiologists feel that this technique should be limited to procedures that can be completed within two hours because of the restriction of arterial blood flow to the extremity. However, prolonged intravenous regional anesthesia for up to four hours[1] has been described in the literature by the technique of deflating the tourniquet after one to one and a half hours and a few minutes later reinflating it and then injecting one half the initial dose of local anesthetic. This may, of course, produce some discomfort during the time the tourniquet is deflated.

Circulatory Anesthesia

One of the major problems that has developed with intravenous regional anesthesia has been the problem of tourniquet release and consequently the release of perhaps large amounts of anesthetic agent into the circulation which, of course, will very rapidly reach the brain. Many studies of blood levels[4] of local anesthetics following the release of the tourniquet have been reported and indicate that peak concentrations are usually achieved at about five minutes after release. Approximately 15 to 30% of the local anesthetic injected into the isolated limb is found to reach the systemic circulation upon immediate release of the tourniquet. It has also been noted that the blood level of local anesthetic achieved after release of tourniquet in patients receiving regional intravenous anesthesia was less than the blood level of local anesthetic in patients receiving axillary, brachial plexus, lumbar epidural or caudal block.[4]

Mode of Action

It is thought that xylocaine or any other anesthetic agent in intravenous regional anesthesia travels out of the vascular space and through the tissues to reach the nerves or nerve endings themselves.[5] One study showed that intravenously injected procaine and xylocaine reduced nerve conduction in experimental animals in small but not in large-diameter myelenated axons. Since pain is conducted in the small myelenated axon and in some non-myelenated axons, this would give adequate cause for the pain relief achieved by intravenous regional anesthesia.[2]

Summary

The technique of intravenous regional anesthesia is described and recommended for use by general surgeons and others doing general medical and surgical work. The technique is nearly 100% successful if properly administered and complications are few and easily avoided. The safety of the technique is described and references to recent works in the literature show that the blood levels following this are certainly no greater than after other regional anesthetic techniques. Although we are not certain at this time of the exact mechanism of action of intravenous regional anesthesia, some of the more recent and plausible theories have been alluded to in this paper.

Boys will be boys, and so will a lot of middle-aged men.—Kin Hubbard

Shakespeare: Diseases

Syphilis*

Timon was a wealthy noble Athenian who became disillusioned with the world because of its numerous evils and vices: war, prostitution, and particularly, human perfidy and corruption. Before his cave of self-imposed exile he had been approached by Alcibiades, the Athenian general, and his mistresses, who unashamedly confessed that they would do anything for gold. They pressed Timon for money until he became so incensed that he commanded them to betake themselves away, upbraiding them harshly for their venality and impudence.

Where else could be found a more devastating description of the ravages of syphilis than Timon's excoriating charge to the two prostitutes who solicited him for gold?

Consumption[1] sow
In hollow bones of man: strike their sharp shins,[2]
And mar men's spurring.[3] Crack[4] the lawyer's voice,
That he may never more false title plead,
Nor sound his quillets[5] shrilly; hoar[6] the flamen[7]
That scolds against the quality of flesh,
And not believes himself; down with the nose,
Down with it flat; take the bridge quite away[8]
Of him, that, his particular[9] to foresee,
Smells from[10] the general weal; make curled-pate ruffians bald,
And let the unscarred braggarts of the war
Derive some pain from you; plague all;
That your activity may defeat and quell
The source of all erection. Timon of Athens IV, III

To say what you mean without ever offending people is usually to say what you mean without making them believe you mean what you say.—James Hilton

---

Senior Peers

I have found no differences that are absolute between Eastern and Western life except in the attitude toward age. In China, the first question a persons asks the other on an official call is: "What is your glorious age?" If he replies apologetically that he is 23 or 28, the other generally comforts him by saying that he still has a glorious future, and that one day he may become old. Enthusiasm grows in proportion as the gentleman is able to report a higher and higher age, and if he is anywhere over 50, the inquirer drops his voice in humility and respect. People actually look forward to the celebration of their 51st birthday.—Lin Yutang

Coarctation of the Aorta in Veterans

M. L. BEARD, M.D.*
Y. SAKO, M.D.*
Minneapolis, Minnesota

DURING A 19-year period (1948-1967), 18 veterans with coarctation** of the thoracic aorta have been admitted to the Veterans Administration Hospital.

Diagnosis

The detection of coarctation of the aorta in the young adult is generally considered to be relatively straightforward, most frequently made possible by the finding of a discrepancy in pulse strength and/or pressure between the upper and lower extremities. Other common findings are the occurrence of a bruit over the course of the thoracic aorta or intercostal vessels, x-ray findings of a prominent aortic knob or left subclavian artery, or rib erosion in the intercostal artery groove. Abdominal aortic coarctation or aortic occlusion secondary to arteriosclerosis, particularly in the older patient, also enters into the differential diagnosis; and appropriate procedures such as aortography may be indicated and are generally performed in most instances of suspected coarctation in recent years.

Despite the relative ease with which aortic coarctation can be diagnosed on physical findings, symptomatic coarctation of the aorta may go undetected for many years. All of our patients had been examined on several occasions, and some had been rejected for one service but subsequently accepted for another. Two had passed fairly detailed medical examinations and qualified to serve as pilots. Another served in the Marine Corps for five years and still another in the Army for six and one-half years. Several had been unduly penalized for suspected malingering because of their inability to participate in physical activities due to leg fatigue or to syncope or headaches associated with increased activity. Similar observations have been made by Sellars and Hobsley,[1] who described accidental discovery of coarctation in school children and in adults who were army commandoes, champion swimmers, and boxing

*Department of Surgery, University of Minnesota and the Veterans Administration Hospital, Minneapolis.
**See Test Your Word Score Page 797.

competitors.

Coarctation of the aorta is generally considered incompatible with a normal life span. The average age of death in patients with untreated coarctation is in the mid-third decade of life[2]. Coarctation endangers life because of hypertension and its sequelae, such as aortic rupture, cerebrovascular accident, congestive failure, valvulitis, and endocarditis[3]. The occurrence of bicuspid aortic valve in 30 to 40 per cent of patients with coarctation has long been known. Such valves are apparently vulnerable to bacterial infection, and probably more so in hypertensive patients.

Indications for Surgery

The indications for and the technical considerations for the surgical treatment of aortic coarctation are now well recognized and have become standardized[4,5]. Many centers have reported on series consisting of hundreds of cases with a very low mortality rate. The most favorable period for correction of the coarctation is around the ages of seven to 15 years, when the aorta will have attained such size that even if the anastomotic site did not grow appreciably there would be no relative stenosis later in life. Correction during an earlier period or in infancy may, however, be necessary if cardiac failure cannot be controlled or if hypertension becomes severe. Because of secondary changes in the aorta surgical correction tends to be more difficult in older patients, particularly in those beyond the third decade of life. These dangers are now largely minimized by the utilization of either bypass, end-to-end, or patch grafts of prosthetic arterial substitutes.

Physical and X-Ray Findings

In our series the ages ranged from 19 to 60 years, with the majority in the 20 to 35-year range (Table). All have had one or more

TABLE
COARCTATION OF THE AORTA IN VETERANS

Age When Admitted	Preop Blood Pressure	Date of Operation	Years Followed
20	164/90	4/6/49	1 yr.—BP 145/70—Then moved to Neb.—Present status unknown.
24	170/95	2/25/50	10 yrs.—BP 150/76—Then moved to Calif.—Present status unknown.
27	180/98	3/8/51	16 yrs.—BP 150/70—Working as a carpenter.
29	190/130	7/12/51	12 yrs.—BP 114/80—Present status unknown.
32	210/120	2/19/54	9 yrs. BP 142/82—Worked as a painter—Present status unknown.
29	168/106	7/2/54	13 yrs.—BP 130/80—Working as a bookkeeper.
45	160/110	8/29/55	Died 11 months postop in another state. Diagnosis on death certificate—coronary occlusion.
30	156/90	9/15/55	8 yrs.—BP 120/70—Then moved to Calif.—Last heard from in 1963—Current status being sought.
19	160/80	3/13/56	11 yrs.—BP 110/60—Working as a mechanic.
31	180/90	9/9/57	10 yrs.—BP 154/72—One year postop—Now living in Calif. Current status being sought.
35	190/110	2/15/61	7 yrs.—BP 160/90—Three months postop—Working as manager of paper firm—Recent BP being sought.
36	160/90	4/3/61	7 yrs.—BP 135/80—Working as a farmer.
30	150/80	3/8/63	5 yrs.—BP 108/70—Working as a barber.
43	200/110	12/16/63	4 yrs.—BP 142/90—Working as a farmer.
37	150/80	12/2/66	1 yr.—BP 130/70—Working as heavy equipment operator.

Patient, Age 34, BP 164/92, Refused operation and left hospital in 1950. Relatives report patient died in 1963 at age 47, cause unknown.

Patient, Age 60, BP 200/96, First seen in 1955. Operation not done due to old age. BP 196/58 in 1960. Died at age 76 of congestive heart failure.

Patient, Age 37, BP 190/100, Refused operation and left hospital on 8/6/57. Present status unknown.

symptoms of recurrent headaches, shortness of breath, chest pain, aching legs, claudication, and episodes of dizziness. Varying degrees of hypertension were noted, some discovered on routine physical examination for work or for insurance (Table). Systolic and diastolic bruits over the precordium and along the scapula were present in all. About one half of the group had bruits along the intercostal arteries; 15 had rib erosion. Other x-ray findings were prominent aortic knob and left subclavian arteries. Only five underwent studies such as aortography and cardiac catheterization.

Surgery

Surgical correction was done in 15 patients. Two patients declined operation and one, age 60, was considered a poor surgical risk with operation not advised; but he lived to be 76 years of age.

Excision of the coarcted segment and end-to-end anastomosis were performed in 14 patients; and one 43-year-old patient had a 4 × 2½ cm. diamond-shaped dacron patch applied after an incision into the coarcted segment and into the aorta above and below the constriction because of large thin-walled collateral and intercostal arteries and post-stenotic dilatation and sclerosis of the aorta. All had the adult type of coarctation; in two a small opening was found in the ductus arteriosis. All patients survived the operative procedure.

The long-term follow-up information is listed in the Table. One patient is known to have died, and two in the non-operative group are known to be dead. After a variable period of follow-up, four in the operative group have not been traceable, and one in the non-operative group is lost to follow-up. Recent information is available in the remaining ten patients: they are well and working. All have responded favorably to fall in blood pressure, some more significantly than others. Symptomatic relief was also reported in all of the patients. Femoral and leg pulses became normal.

Summary

Experience with management of coarctation in 18 veterans is reviewed. This series is of some interest because it represents a group in whom the lesion eluded detection despite examination for physical fitness. More importantly, however, this group shows that coarctation in the adult may be excised safely with a favorable symptomatic response and lowering of the blood pressure.

DERIVATIVELY SPEAKING

Abdomen—possibly from Latin *abdere* (to hide)

Everything is simpler than you think and at the same time more complex than you imagine.—Goethe

The Heart Besieged

A young woman was brought in with a chest wound. She was hit from a pistol twenty minutes before, and her condition was serious. The surgeon found a tiny hole in her chest, but no second hole to show that the bullet had left the body. There were unmistakable signs that it had lodged itself in the heart or near it. The uncertainty of its exact location had the greatest bearing on what came after. The chance of saving the woman hinged on the hope that the bullet was embedded somewhere outside the heart.

The operation began. The surgeon exposed the heart. The wound was in its front wall, in the region of the right ventricle. The surgeon sutured it, and in making the final stitch his fingers encountered a solid object in the heart muscle. The bullet had penetrated the front wall, passed through the cavity of the ventricle, and lodged itself in the back wall of the heart.

That was just what the surgeon had feared most. To reach and extract the bullet he would now have to incise the wall of the ventricle. But that would mean a second wound to a heart muscle already damaged and copiously flooding the site of the operation with blood. Moreover, the surgeon would have to manipulate on the back wall of the ventricle, which was hidden from view. In that day it all appeared virtually impossible. To top it all, the bullet was lodged in the immediate neighborhood of the descending branch of the right coronary artery. Utmost care was required to avoid damage to this vital vessel.

The life of the patient hung on a thread, as it were, which grew slimmer and slimmer with every passing second. But the surgeon hesitated only for an instant. The operation continued. He drew out the heart as far as it would go, transfixed the heart muscle with two sutures, and cut the back ventricle wall. The cut was made in the direction of the bullet, opening access to it.

The silence of the operating room was soon broken by the sound of metal striking glass. The doctor had extracted the bullet and dropped it into a bowl. The operation ended happily.

That was how Manteufel, a Russian surgeon, made medical history in Yuriyev on September 12, 1905.*

A Jaw Dislocation

Gruelling as the ambulance work was, it always provided a welcome escape from the tense situation within the hospital, and sometimes the call would have its humorous aspects. One day a worn-out old woman with a grievance was at last having her day in court, letting the judge know all about it. As she got deeply into her story her excitement rose. She was finally gesticulating and shrieking with her mouth wide open striving for even greater eloquence when her jaw clicked. And there she was, poor thing, in agony with a dislocation, in greater mental agony that she had been silenced in her great moment.

A hurry call brought me from the hospital to the courtroom and there surrounded by fascinated onlookers, I was fortunate enough to be able to reduce the dislocation quickly. Another click and her jaw bone was back in place and then the torrent of words started right in, just where she had left off. As I went from the courtroom she was still going strong, and somehow I believe she may have won her case.*

Neointimae

Smooth Muscle Cells in Replacement Teflon Prosthetic Grafts

T. SHIMAMURA, M.D.*
Vermillion, South Dakota

T. KAWAKAMI, M.D.**
A. C. BEALL, M.D.†
Houston, Texas

SMOOTH MUSCLE cells have not been observed by the extensive study on neointima‡ (Figure 1) of human Dacron arterial prostheses reported by DeBakey et al.[1] However, they have been demonstrated in the neointimae of arterial prostheses in the baboon[2] and in young growing pigs.[3] We are reporting the observation of morphologically characteristic smooth muscle cells in neointimae of canine infrarenal caval replacement Teflon prostheses.

Method

The infrarenal caval segment of five centimeters in length was replaced with a woven Teflon prosthesis in nine adult female dogs. At the same time, a side-to-side anastomosis was created between the 1-to-1.5 centimeter long incisions that were made in the wall of the right femoral artery and vein.[4,5] The femoral vein was ligated immediately distal to the fistula, and a collapse of the lumen was prevented by placing three stainless steel rings around the external surface of the prosthesis.[6] Four out of nine cases showed widely patent lumen until the time of their sacrifice by intracardiac injection of pentobarbital sodium at 26, 34 and 36 weeks (two cases) after the operation. The neointimae of only these four cases was studied. Of the excluded five dogs, two were killed at two and three weeks respectively without occlusion or stenosis of the lumen. The remaining three were killed in earlier phases of the experiment because of an occlusion or stenosis of the lumen.

Parts of the neointimae from the central segment of graft of these dogs killed at 34 and 36 weeks (one case) were fixed in Mil-

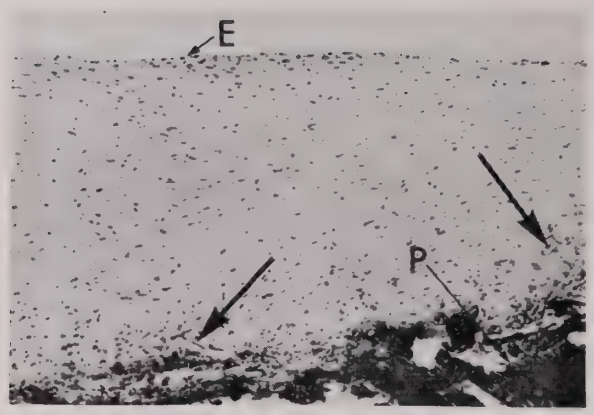

Fig. 1—A single layer of endothelial cells (E) lines the luminal side of the tissue. Immediately adjacent to the prosthetic material (P) is a mild foreign body reaction. The arrow indicates newly formed vasa vasorum. Hematoxylin and eosin stain. Mag. 45X.

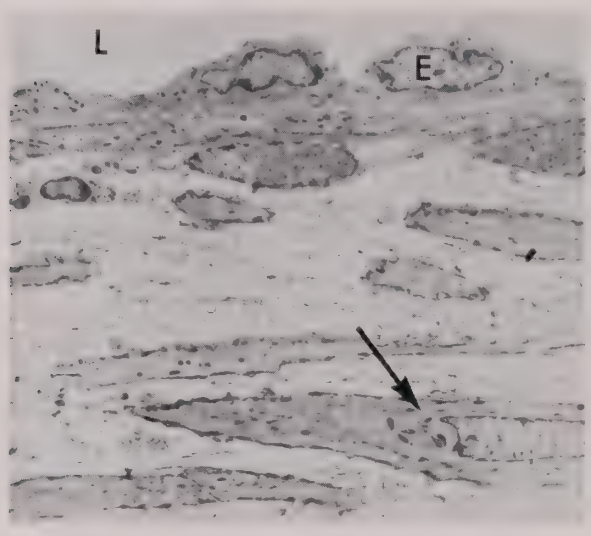

Fig. 2—Many smooth muscle cells are seen in parallel arrangement to the endothelial cells. L: vascular lumen. E: endothelium. Mag. 3300X.

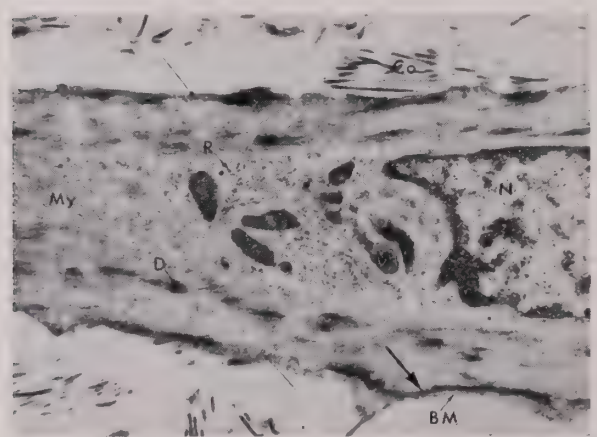

Fig. 3—Smooth muscle cells showing characteristic myofilaments. D: focal cytoplasmic electron dense area. M: mitochondria. N: nucleus. R: ribosomes. BM: basement membrane-like material. Co: collagen fibers. Mag. 25000X.

lonig-buffered[7] osmium tetroxide for one hour, dehydrated and embedded in a half-and-half mixture of Epon and Araldite. Thin sections were cut on a Porter-Blum microtome, double-stained with lead citrate[8] and uranyl acetate, and examined with an RCA-3G electron microscope. The remaining tissue from the four cases was fixed in 10% neutral formalin, embedded in paraffin, sectioned at a thickness of 6 microns and stained with hematoxylin and eosin for light microscopy.

Results

Endothelial Cells

The inside walls of these four prostheses with widely patent lumens were lined by a thin layer of semitranslucent gray smooth glistening tissue. The light microscopic section of the tissue showed fibrous connective tissue covered by a delicate single layer of endothelial cells (Figure 1).

Smooth Muscle Cells

By electron microscopy, morphologically characteristic smooth muscle cells were observed within the fibrous connective tissue (Figure 2). These cells were spindle-shaped, with abundant parallel myofilaments, which often appeared condensed to form electron-dense foci in the cytoplasm. The cell borders showed many vesicles. Nuclei were located centrally; and small numbers of mitochondria, ribosomes, and traces of rough-surfaced endoplasmic reticulum were seen in the paranuclear area. These cells were frequently surrounded by a basement membrane-like material (Figure 3).[9,10]

Connective Tissue

Ingrowth of connective tissue from the outside areolar tissue into the neointima through the tightly-knit prosthesis was not observed by us in the examination of the light and the phase microscopic sections.

Comments

We assume that the smooth muscle cells either grew from the line of anastomotic sites toward the center of the prosthesis or originated from cellular elements of the blood. It has been reported that the new inner layer which forms in the prosthesis proceeds from the lines

of anastomosis toward the center and is able to cover the entire inner wall if the length of the graft does not exceed 4 cm.[11] We are uncertain whether or not the smooth muscle cells will similarly appear in the central part of the woven Teflon replacement caval prosthesis of a much longer segment.

Summary

The neointimae of long-term patent canine infrarenal caval Teflon replacement prostheses were found to have endothelial cells and smooth muscle cells. The smooth muscle cells were present as the major cellular component in these neointimae.

Hunter's Deer Antler Experiment

In the most roundabout way, an animal experiment sometimes led him to a new principle in human surgery. Once while studying the growth of antlers in deer, Hunter found that if he tied off the artery to the head on one side the antler became cold, but in a few weeks the circulation was completely restored. Autopsy showed that the blood had been shunted through other blood vessels.

Many years later he applied this observation to a patient with a clot inside a large pocket of a stretched and bulging artery in the knee. The customary treatment was to tie the vessel above and below the clot, and then scoop the clot out of the bulging pocket (aneurysm). The procedure was fatal so often that amputation was considered safer. Hunter recalled the experiment with the deer's antler. He tied the large artery in the triangular space (now called Hunter's canal) between three muscles above the knee, shutting off that branch of the circulation. Within six weeks the patient was well, his leg having been nourished by the blood shunted from neighboring connecting vessels. Since then this procedure for treating aneurysm has saved many a limb as well as life.*

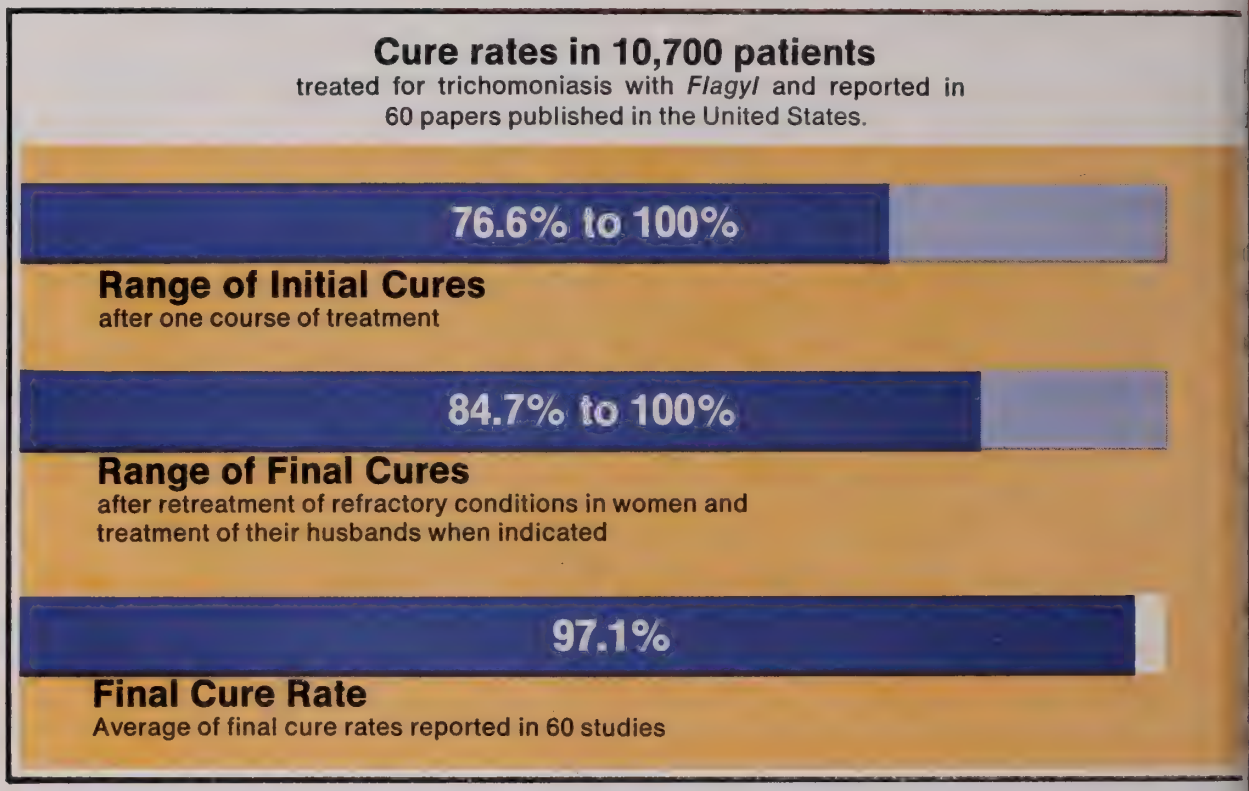
Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.



Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

True Drug Failure...

How often does it occur

Indications: Flagyl is indicated only in the treatment of trichomoniasis in both men and women.

Contraindications: Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precaution: Complete blood cell counts should be made before, during and after therapy, especially if a second course is necessary.

Side Effects: Infrequent and minor side effects include nausea, metallic taste and furry tongue. Gastrointestinal disturbances, flushing and headache sometimes occur, especially with concomitant ingestion of alcohol. The taste of alcoholic beverages may be altered. Other effects, all reported in an incidence of less than 1 per cent, are diarrhea, dizziness, vaginal dryness and burning, dry mouth, rash, urticaria, gastritis, drowsiness, insomnia, pruritus, sore tongue, darkened urine, anorexia, vomiting, epigastric distress, dysuria, depression, vertigo, incoordination, ataxia, ab

with Flagyl®?

brand of

metronidazole

n clinical practice an occasional uncooperative or drug-sensitive patient r spouse makes 100 per cent cure of trichomonal vaginitis in large series f patients difficult.

Further a very few patients who apparently absorb Flagyl poorly nd a few rare instances of trichomonads resistant to Flagyl have been eported. Nevertheless, approximately half the United States investiga- ors report a final cure rate of 100 per cent with Flagyl.

Sixty papers[1] published on the use of Flagyl in trichomoniasis in the Jnited States and comprising a total of 10,700 patients have been evalu- ted. In thirty of the papers it was declared that all patients adequately ollowed and treated were free of trichomonal infection.

Analysis of all of these papers shows that the incidence of cures for he *initial* course of therapy ranged from 76.6 per cent to 100 per cent. The cure rates after retreatment of female patients and treatment of their usbands when indicated ranged from 84.7 to 100 per cent. The average inal cure rate reported in all investigations was 97.1 per cent.

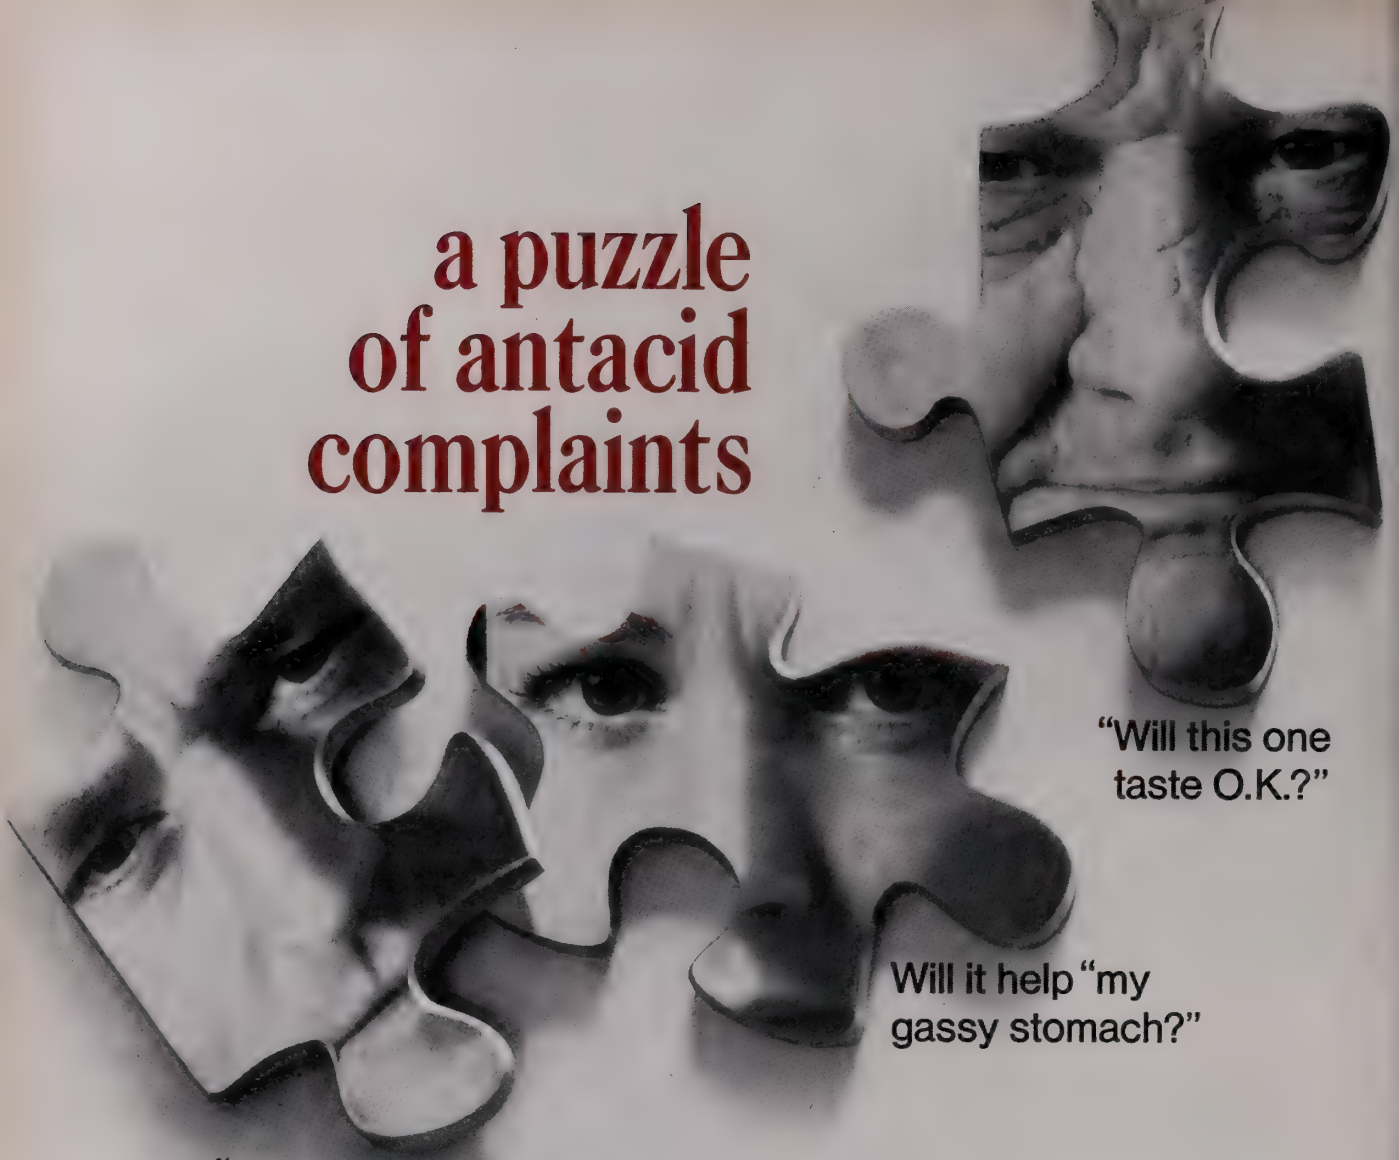
dominal cramping, constipation, stomatitis, numbness or paresthesia of an extremity, joint pains, confusion, irritability, weakness, cystitis, pelvic pressure, dyspareunia, fever, polyuria, incontinence, decreased libido, nasal congestion, proctitis and pyuria. Elimination of trichomonads may aggravate candidiasis.

Dosage and Administration: In women: one 250-mg. oral tablet three times daily for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When used, one vaginal insert should be placed high in the vaginal vault each day for ten days; concurrently two oral tablets should be taken daily.

In men: When trichomonads are demonstrated, one 250-mg. oral tablet twice daily for ten days in conjunction with treatment of his female partner.



Dosage Forms: Oral tablets—250 mg.
Vaginal inserts—500 mg.

Minnesota Medicine Joins the 50 Year Club

VOLUME 1, No. 1 of MINNESOTA MEDICINE appeared in January of 1918. This same year 17 physicians whom we honor this year entered into the practice of medicine.

These physicians* received their 50-club pins at ceremonies last month at the Annual Meeting of the Minnesota State Medical Association in Rochester. This is a scintillating company of doctors whose work is now part of Minnesota history. Particularly distinguished are those great men who helped transform the medical school into the world-renowned institution of today.

Prior to 1918 "THE JOURNAL OF THE MINNESOTA MEDICAL ASSOCIATION" appeared as a section of the JOURNAL LANCET. The new MINNESOTA MEDICINE owned and controlled by the state organization ventured forth into the medical world under the editorship of Dr. Ernest T. F. Richards of Saint Paul, who no doubt wrote this "Salutatory" of MINNESOTA MEDICINE: "Now that the Minnesota profession has taken this step, it is a foregone conclusion that it will never regret it and will soon feel the value of the bond its own journal will make between its various component county and district associations, and above all the bond that will bind the entire membership into a more homogeneous whole. There is no better instrument to do this thoroughly than a mutual interest in the success of an undertaking." Subscription price was $2.00 per annum in advance, single copies 25¢, foreign countries $3.00 per annum. There have been three editors since Dr. Richards, namely: Dr. Charles B. Drake, Dr. Arthur H. Wells, leading up to our present Editor-in-chief, Dr. Carl O. Rice, who was a teenage boy with the American Expeditionary Forces in France in January, 1918.

The year of 1918 was one of glory for the United States with the troops coming home victorious from World War I in France, Belgium, and Germany. Woodrow Wilson was the man of the year who would lead the world out of purgatory into a democratic heaven.

Volume I of MINNESOTA MEDICINE is a mirror of the times and the following quotations are taken from it:

Tonsillectomy was near the zenith. "Joint, heart, kidney, goiter and glandular conditions show such marked improvement after tonsillectomy as to leave no doubt as to the source of infection." (Gillespie, N.H., page 21). However, not everyone agreed. "While

DOW

it may seem presumptuous and foolhardy in this enlightened medical age to question, it is my sincere belief that the profession has gone plum loco on the tonsil question, and that they are barking up the wrong tree. I regret that one of the latest fantasies in the treatment or prevention of rheumatism seems to have been found in tonsillectomy." (James, J.H., page 23). Doctor Charles N. Spratt said: "Like Banquo's ghost the tonsil question is ever before us and it is still unsettled. I divide my tonsil cases into two classes—those in which I make a diagnosis at the office from the appearance of the tonsil, and those in which we make a diagnosis over the telephone, or from what the patient tells me. The first variety is the large hypertrophied tonsil, diseased or not, and in the second variety one makes the diagnosis from the history, namely repeated attacks of tonsillitis or rheumatism."

Advertisement: "Good location, open for position. There is a splendid opening at South Shore, South Dakota, for a doctor who can run a small drugstore in connection with his practice."

Of General Interest: "Lt. Theodore H. Sweetser of Minneapolis, son of Doctor H. B. Sweetser, has been recommended for the British War Cross for bravery and devotion to duty near Paschendale on March 13. Lt. Sweetser attended to 40 gas victims although he was himself suffering from the poison gas." "Dean Wulling and his co-workers in the College of Pharmacy, University of Minnesota, during the past year prepared 28,000 half-pint bottles of tincture of digitalis. This constituted the complete supply of the drug used in the United States army."

"Some of you probably heard what Sir James McKenzie said in Chicago at the meeting of the American Medical Association. I heard him discuss effort syndrome, in which he brought out conclusively the fact that he was sorry the stethoscope had ever been invented, meaning by that, we have been paying too much attention to the morphology of the heart and not enough to its function." (Discussion by Doctor H. L. Ulric of a paper by Olga S. Hanson). Doctor Hanson's paper discussed the value of that new instrument—the electrocardiograph in cardiac diagnosis. Sir James' deprecatory remarks about the stethoscope in 1918 apply equally well in 1968 and could be extended to include the electrocardiograph whose evidence unsupported by symptoms can do more harm than good.

News From Abroad—"Dear Doctor Farr (Robert Emmet Farr). I thought you would be interested to know how I spent the leave which I have had in Blighty. I visited Professor E. Thompson (Edinburgh). He performed an excision of the rectum for carcinoma 2½ weeks after a permanent preliminary colostomy. He reported that since he made a permanent artificial anus and did not attempt to save the sphincter, his percentage of recurrence in rectal cancer was greatly reduced." (Stanley R. Maxeiner, Capt., M.C., U.S.A., page 70).

I also took part in the war effort, recalling after a half century the three-minute speech exhorting* fellow students at Harrison School in the fifth grade to buy liberty bonds.

Thought for Today

Thank God every morning when you get up that you have something to do which must be done whether you like it or not. Being forced to work, and forced to do your best, will breed in you temperance, self-control, diligence, strength of will, content, and a hundred other virtues which the idle never know.—Chas. Kingsley

"Undress," as George Herbert says, "your soul at night," not by self-examination, but by shedding, as you do your garments, the daily sins whether of omission or commission, and you will wake a free man, with a new life.—William Osler

Doctors think a lot of patients are cured who have simply quit in disgust.—Don Herold

The AMBAR SCRAPBOOK of Obesity Oddities
FACT & LEGEND

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg., phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

Research*

With respect to the expenditure of public funds for the purpose of research in general, the federal government within recent years has assumed a major role and seems destined to play a larger and larger part as time goes on. By 1966 the federal share for research expenditures amounted to approximately 70% of the funds spent in this country on biomedical research. With the total national biomedical research program now having grown to a multibillion dollar enterprise, perhaps it is time to sit back and reflect on how judiciously this segment of the federal fiscal outlay is being managed, with a view toward implementing changes that would ensure the most fruitful return.

The Surgeon General of the Public Health Service recently stated: "Free scientific inquiry is the foundation upon which the entire complex rests." There is great wisdom in this statement and the message it bears deserves very thoughtful attention. Any attempt to improve the quality and the quantitative yield of research must give priority to considerations which will allow free scientific inquiry to operate unimpeded. Philosophical confidence in the humanitarian generosity of others must not relate the anticipated research productivity directly to the amount of fiscal outlay. Spectacular achievements often emanate from well thought out but poorly funded research programs. More lavishly supported programs may be unproductive because they are nourished by unimaginative minds or because there may be factors operating which act to restrict the talents of the researchers. Energies must be directed toward finding ways to unleash the creative genius of the scientific mind. Ideas are born of the minds of men and not of fiscal coffers.

In order to establish a research setting conducive to free scientific inquiry the investigator must be freed from the "political" aspects connected with research. Perhaps once a grant award is made to a researcher he should be invested with sufficient control over his funds, so that the direction of his program resides in his hands. He should be guaranteed continuity in the use of the funds over the entire period for which the grant award was made. Such assurances are essential to ensure productive use of research funds.

The artificial heart research program promises to become a multibillion-dollar federal undertaking. It is important that the system under which research is carried out in this country be carefully reviewed and overhauled prior to obligating such an immense portion of public funds. The time and effort taken in doing this will be rewarded by an improvement in the quality of research, not only in the artificial heart program, but in research programs generally.

Tympanoplasty for Chronic Otitis Media

The literature in Otology from the earliest stages contains repeated references to efforts in eliminating disease from the ear while preserving its function. In the early stages, successful accomplishment of these aims was limited by the inability of the unaided eye to see the small structures of the ear sufficiently well to allow conservative surgery. During the past quarter century, increasing use of magnified vision in otologic surgery has allowed increasing refinements in techniques. The use of magnifying loupes was of great benefit, but the degree of magnification was limited. Development of the surgical microscope, which allows magnification up to 40 power with adequate working distance, gave great impetus to the

your patient can feel better while he's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In bacterial/allergic u.r.i., ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the tetracycline-sensitive organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Average adult dosage: 2 tablets four times daily, given at least one hour before, or two hours after meals.
Contraindications: History of hypersensitivity to any component.
Warning: If renal impairment exists, even usual doses may lead to liver toxicity. Under such conditions, lower than usual doses are indicated and, if therapy is prolonged, serum level determinations may be advisable. Hypersensitive individuals may develop a photodynamic reaction to natural or artificial sunlight during use. Individuals with a history of photosensitivity reactions should avoid direct exposure while under treatment, which should be discontinued at first evidence of skin discomfort.
Precautions: Some individuals may experience drowsiness, anorexia, and slight gastric distress. If excessive drowsiness occurs, it may be necessary to increase the interval between doses. Persons on full dosage should not operate any vehicle. Use may result in overgrowth of nonsusceptible organisms. If infections appear during therapy, appropriate measures should be taken. Infections caused by beta-hemolytic streptococci should be treated for at least 10 full days to help prevent rheumatic fever or acute glomerulonephritis. Use of tetracycline during tooth development may cause discoloration of teeth.
Adverse Reactions: Gastrointestinal—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes (a case of exfoliative dermatitis has been reported); photosensitivity; onycholysis and discoloration of nails (rare). Kidney—rise in BUN, apparently dose related. Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. In young infants, bulging fontanels following full therapeutic dosage has been reported. This has disappeared rapidly when drug was discontinued. Teeth—dental staining (yellow-brown) in children of mothers given tetracycline during the latter half of pregnancy and in children given the drug during the neonatal period, infancy, and early childhood. Enamel hypoplasia has been seen in a few children. Blood—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. Liver—cholestasis (rare), usually at high dosage. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy.
